In connection with the topic of this paper, it may be profitable to call attention to a subject recently discussed by H. V. Winchell regarding the differences in surface appearance and mineralization between southern ore deposits and those formerly covered by the continental ice sheet, or, roughly speaking, north of the 45th or even 40th parallel of latitude in Eastern America.²⁰ This geologist points out what probably most of us know, did we stop to consider, that even were the rocks of these regions unplaned and undegraded by the ice sheet, the natural oxidation and decomposition of their vein croppings would be much slower than in southern, especially tropical, latitudes, hence the consequent secondary enrichment of such lodes is necessarily less. The planing down by the great continental ice sheet of the Pleistocene or Glacial period must have removed much if not most of the oxidized portions of these outcrops, except in places which may have been sheltered from this titanic leveler by reason of local topography or perhaps minimized by some other cause. Hence what remains today is either the roots of deposits of secondary ore or else primary ore veins which are likely to extend downward to considerable depths. Winchell claims that boreal regions seldom contain extensive deposits of secondary ore, that is, upper portions of primary deposits

enriched by secondary deposition. That such roots are likely to be as productive as secondary enriched lodes in unglaciated regions is not to be expected. Speaking in very general terms, their primary character would tend to render them low grade, but with the compensating advantage of probable persistence with depth. I take it that the practical point which Winchell here desires to emphasize is that in glaciated regions and those far north or south where, by reason of the cold, but little alteration could take place, the lode outcroppings are quite different from what may be expected in more temperate, especially tropical, countries. In warm regions outcrops may even be deceptive, since by excessive oxidation and decomposition a larger and richer deposit might be indicated than subsequent development exposes. In glaciated areas the planed-down rocks are likely to expose the lode at the surface in much the same condition as it exists a hundred or more feet in depth, that is, all superficial alterations have been sliced off, leaving the unaffected stump cropping to the light of day. Even though such veins be but the roots or stubs of once greater lodes, and are thereby likely to be of infinitely less value than when in their pristine condition, there is a compensating advantage in that the true character of the veins in such glaciated areas may be determined with comparative ease by simple surface trenching. In more southern unglaciated areas considerable depth must usually be attained before the original character of a lode can be studied with accuracy.

The most serious difficulties to overcome in deep mining are threefold—hoisting, high temperatures, and rock pressure. The mechanical problem of hoisting from depths of 5000 ft. is probably the least of these, and has been pretty well worked out in South Africa and at the copper mines on Lake Superior. When such shafts depart from the vertical in part of their course, the best practice seems to be to hoist in stages; in fact, it is not unlikely such a system may be found in many cases the most economical even where the shafts are wholly vertical, especially now that electrical appliances have reached such a high degree of efficiency.

The normal increase of rock temperature with depth is a more serious matter, although so far it has been capable of control, for while there is a steady rise of something like 1° F. for each 208 ft. (beginning with an average of 60° F. at surface) of depth in the South African gold mines,²¹ and 1° F. for each 103 ft. in the Lake Superior copper mines,²² good ventilation overcomes much of the discomfort from this source. In cases where the surrounding rocks are chiefly or wholly of eruptive origin, the rock temperatures are likely to be even higher. In the Comstock, for example, at the 2000 and 2100-ft. levels it ranges between 111° and 119½° F.²³ In the Savage mine, on the same lode, at a depth of 2200 ft. a spring of water having a temperature of 154° F. has been tapped.²⁴ In the Victoria Reef Quartz shaft at Bendigo the rock temperature is about 110° F., the water issuing therefrom 114° F.²⁵ At the bottom of the Nueva Luz shaft, 2000 ft. deep, at Guanajuato, Mexico, rock temperatures of 106° F. are now found.

It must not be assumed that the deeper the crust of the earth is penetrated the uniformly greater the heat, for some increase in rock temperature may be due to local phenomena, such as oxidation of the sulphides of the kaolinization of the feldspars. Thus, in the Comstock, the rise of temperature is not progressive below the 2000-ft. level. In fact there seem to be belts or zones of high temperature which rises to a maximum of about 2000 ft., followed in depth by a slight decrease. It should not, however, be concluded from this that there is not in general a normal rise of rock temperature on penetrating into the earth, for there undoubtedly is such in all kinds of

rocks; in other words, the earth becomes progressively hotter toward its centre. There have been many calculations as to what this increment of increase may be; but it is safe to say, as a rule, they are far from accurate; for, as we have seen, local conditions often import disturbing influences.

The increase of rock pressure in deep workings is probably the most serious difficulty of all, one likely to make the methods of supporting the roof increasingly costly with depth. It seems likely that steel and concrete and especially waste rock filling may be used in such instances to marked advantage, where in higher levels timber would suffice. One thing is certain, that in most cases whatever methods are adopted the expense is likely to increase out of all proportion to the profits. Moreover, the outlook for a decrease of cost in this respect is not hopeful, unless it be in the direction of flushing with tailing and fine dump material. These methods, or at least schemes of a somewhat similar character, have been carefully studied and used in the anthracite coal district of Pennsylvania and in the gold mines of the Transvaal.

In summing up the discussion attempted in this paper, I am impressed by the inconclusiveness of my conclusions. In fact, the nature of the subject precludes definiteness, except in a few broad principles. Probably it may be generally conceded that fissure veins will not contain profitable ore to indefinite depths. It must be recognized that a deep orebody which may not pay to work today, might be profitable in the next decade by reason of improved mechanical and electrical equipment as well as greater economy and efficiency in milling practice. General experience throughout the world tends to the conclusion that metal-bearing veins of all kinds, with some exceptions, show a marked decrease of value as depth is attained below the 1500 or 2000-ft. levels. Among the exceptions might be cited the Perseverance mine at Kalgoorlie, Australia, where the bottom levels are richer than the intermediate horizons between 1300 and 1750 ft.²⁶ Again, at Mysore, India, at several points in the bottom levels the gold content is high; thus, for instance, at the 2790-ft. level in Tennant's section, an average was obtained of about \$37 per ton, for over 4 ft., and at the 4010-ft. level in Bullen's section (Ooregum) the vein is 15 in. and averages 1½ oz. gold per ton.²⁷ MacLaren says of this great Mysore ore-shoot that it has an average width of about 4 ft., and has maintained this general width and value for a depth on its pitch nearly 4000 ft., and it is certainly the most notable shoot known in the history of gold mining.²⁸ At the Waihi mine, New Zealand, the veins are characterized by the continuity of profitable ore both in horizontal and vertical extension.²⁹ It is certainly a notable fact that so far as I am aware few of the deep metal-producing lodes other than iron occur in districts which have been subjected to glaciation. The copper deposits of the Lake Superior region are an exception. It is going too far, however, to assume that because of this the lodes have been eroded away and deep mining may never be expected to be possible in such areas; our knowledge is too slight to accept any such general conclusion. The fear that this condition may be a fact is perhaps justifiable from experience throughout the world, and in some degree is supported by deductive conclusions based on geologic observations. This question is a peculiarly timely one, moreover a very vital subject to Canada in view of the rapid development on the rich lodes of Cobalt and Porcupine.

MONAZITE-BEARING SANDS have been found in streams to the west of Naraguta, in Nigeria. In one case the tin concentrate contained nearly 30% monazite and zircon. The Mineral Survey in 1908 found a good deal of monazite among the granite hills at Kirigama and Kajuru. Analysis of some tin concentrate obtained at Jalingu showed 6% ceria and thorium compounds present.

In the experiments referred to, the effective velocities for an orifice of 1 sq. in. area, at pressures of up to 4 in. water-gauge, were tabulated, with the corresponding discharges in cubic feet per minute (free air.) All subsequent readings for different sizes of orifice were simply referred to this table. Removable screwed caps were used on the receiver with orifices of 0.125, 0.25, and 0.5 sq. in. area, these being simple fractions of 1 sq. in. These different sizes were used to keep the water-gauge readings within reasonable limits and covered all measurements up to 7 cu. ft. per minute, with 3/8-in. pipe and fittings. Pipe sizes do not come into the calculations provided that they are large enough to carry the quantity of air, and the receiver *F* need only be of sufficient size to reduce the kinetic action of the air to a negligible quantity, and give a true reading on the water-gauge. In the above case it was a can of about 2 pints capacity, and for air-lifts, consuming about 50 cu. ft. per minute, an ordinary kerosene

cock *C* closed, and valve regulated to give the same reading as on *I*. The resistance of valve *D* is thus made equal to that of *E*—the orifice. The tank was then nearly filled with water and its level noticed; cock *C* opened and *B* closed and hose connected to tank at *G*. Cock *B* opened and *C* closed simultaneously and free end of hose lowered; reading on *I* noted; when tank nearly empty, *C* opened and *B* closed simultaneously. The time air was passing to tank taken by stop-watch; air in tank reduced to atmosphere pressure (by bringing free end of hose *H* to level of water in tank) and volume of air noted; gauge *I* (if necessary due to any back pressure from tank) brought to same level (as when passing to tank) by valve *E* and reading *J* taken.

The table shows the results of these measurements, using discs with orifice equal to 0.214, 0.441, and 0.797 sq. in.; pressure on mercury gauge equal to 9 lb. per square inch; and volumes of free air from 9 to 16 cu. ft. per minute:

Area Orifice F. sq. in.	Height of Mercury Gauge I	Water Gauge J	Calculated volume flowing through orifice using 0.04 of discharge as in Mr. Weymouth's article Free Air.		Volume passed into tank. Cubic feet.	Time, Seconds.	Volumes in tank. Cubic feet free air.	
			Cubic feet per sec.	Cubic feet per min.			Per sec.	Per min.

tin, with interchangeable orifice plates with openings of 0.5, 1, 2, and 4 sq. in. area, was used, pipe fittings in this case being 1 in. In all cases, the compression in the receiver is so slight that all calculations are as for free air. With the apparatus described above, no difficulty was found in measuring quantities anywhere between 0.5 and 60 cu. ft. per minute. By substituting a high-pressure gauge at *B*, readings can be taken at any pressure, and in any case a little experience soon gives the most suitable size of orifice to use.

C. C. Freeman, metallurgist of the Lake View & Star mine, has submitted the following results of experiments in connection with this method of measuring air quantities. The apparatus shown in the accompanying sketch (Fig. 2) is almost identical with that used by Mr. Weymouth, with the exception of the sealed tank in place of the apparatus to be tested. Owing to the size of the tank used, quantities over 20 cu. ft. of free air per minute could not be tested, but results obtained for smaller flows gave excellent results, and for low-pressure air for agitation and similar purposes in the neighborhood of 5 lb. per square inch this method would be very useful. It consists of measuring the flow of air through a suitable orifice under low pressures, the orifice being varied so as to keep the pressure in the drum low enough to eliminate factors due to variations of volume due to pressure. Tests were carried out as follows:

Valve *A* opened to admit the requisite quantity of air, cock *C* opened and valve *E* regulated to give any required pressure on mercury gauge *I*. A suitable orifice attached to drum at *F* to give a reading on the water-gauge *J* of from 2 to 9 in. Hose at *G* disconnected, cock *B* opened,

these check very closely with the volumes measured in the tank.

THE coating of cement mortar applied by the pneumatic cement-gun which was sent to the Isthmus a little less than a year ago for use in spraying the surface of certain rock faces in Culebra cut which disintegrated on exposure to air, was found not to prevent this disintegration. The concrete mixture sprayed on the smooth surfaces adhered uniformly, but was not sufficiently air-tight to retard appreciably the progress of disintegration. The gun was used recently on the re-located line of the Panama railroad, in coating the surfaces of hand-laid revetment wall, made of hard Bas Obispo rock. In this case the concrete penetrated the interstices between the rocks as far as several feet and thus obtained a firm hold. Using a mixture of 1 part of cement to 3 of sand for the inner coating and 1 part of cement to 2 of sand for the final surfaces, it was practicable to lay a smooth strong coat from 2 to 3 in. thick over an area of about 25 ft. square per day. The spraying was continuous. By the time the work had been carried from one end of the area under treatment to the other, the first part was ready for another coat. In all, about 10,000 sq. ft. of revetment was treated.

CALIFORNIA is the only state which makes a commercial production of borax annually. The output for 1910, according to the U. S. Geological Survey, was 42,357 short tons, valued at \$1,201,842. Less than 1 tons was imported. About one-half of the borax consumed is used in the enameling industry for making kitchen and sanitary ware. Each year some new use is found for the mineral.

Birth of the American Mining Act—II

By H. W. MACFARREN

(Continued from page 526)

EARLY TAXES

In 1864 a tax of $\frac{1}{2}\%$ had been levied upon all bullion produced from public land, to be collected by a stamp tax at the United States assay offices. The following year it was increased to $\frac{5}{8}\%$. The mining bill as introduced by Mr. Sherman contained a clause providing that owners or occupants of a mine patented under this law should pay into the Treasury of the United States, each year until the national debt was extinguished, 3% of the *net* product of the mine in lieu of the stamp tax on bullion from land that still remained unpatented. This was a clause with which Senators Stewart and Conness and the balance of the Western delegation were not in accord. They had allowed it to be included under their protest to conciliate the Secretary of the Treasury and Mr. Sherman and those of Congress who believed that the Western mines should be directly taxed to assist in paying the Federal debt. Following Mr. Stewart's speech, Mr. Sherman moved to amend by making the tax of 3% perpetual. This amendment failed. He next proposed that the tax be raised from 3 to 5%. Mr. Stewart replied that he hoped the amendment would not be accepted. That it was much for them to consent to be discriminated against to the extent of 3%. That the mining industry should be fostered rather than taxed, and the poor man thus further encouraged to try his luck in finding mines so that the metallic currency could be increased. This, he contended, would increase the value of property and make the national debt that much easier to meet. He ended his argument by saying: "It seems to me the whole of this tax is wrong, but we have to submit to something, I suppose, and I trust at any rate it will not be put higher than three per cent." Thereupon followed a debate in which it was apparent that the senators generally considered that the mining industry deserved fostering through bounties rather than to be taxed. Thomas A. Hendricks, senator from Indiana, proposed that the section imposing a tax be stricken out. Mr. Sherman showed his broad character by volunteering to vote for the bill with or without the tax clause.

Mr. Williams, senator from Oregon, now moved to amend by striking out of the bill everything relating to the sale of mineral land. This would have left the bill stating only that mineral lands were open to occupation and development and water rights were open to acquisition under local or district rules and regulations. This would not have changed the nominal condition of mining and water rights one iota; it would simply have been a statutory acknowledgment of what the nation had impliedly given by its silence. It would simply have perfected the possessory right. Mr. Williams made objection upon nearly every point relating to the sale of mineral land, stating that the cost of survey and disposal would be prohibitive and that no rational system could be developed. He appeared to act partly under instructions from some of his constituency, partly from failure to grasp the bill, and partly from a realization of the difficulties of the question, for he said:

I am opposing every system of selling the mineral lands. I say that no system can be devised, and I defy any man to devise any system of selling the mineral lands of the United States at this time that will be found to be wise and just in its practical operation. My judgment is, that when Congress undertakes to legislate generally for the mines of this country it will do those mines an irreparable injury. Congress, when it once commences, will be compelled to tinker with legislation from time to time, until the whole system of mining regulations which has grown up from time and experience, and which is now well adapted to the wants and interests of the miners, will be thrown into inextricable confusion and made the means of endless controversy and litigation.

Senators Stewart and Conness worked with Mr. Williams step by step to show him the error of his way of thinking. James A. McDougall, the other senator from California, agreed with Mr. Williams, stating, after paying his respects to the learning of Mr. Stewart: "This might be called 'a bill to promote litigation, create controversy, and occasion difficulties.' No system yet has been matured for disposing of the mineral lands in fee, except as they are occupied in present possession under the customs of the country. Here is a bill providing a policy full of machinery very ingenious, but which, like some of those machines that are intended to secure perpetual motion, will run but a short time. We are not prepared here at the present time to provide a plan for the disposition of the mineral lands of the country." Mr. Hendricks of Indiana also sided with Mr. Williams. Under these conditions and with this diversity of views, the bill finally passed the Senate on June 28, 1866.

FIGHT IN THE HOUSE

On July 3 William Higby, representative from California and chairman of the House Committee on Mines and Mining, moved in the House to take up the Senate bill No. 257 on mining and refer it to the Committee on Mines and Mining. Mr. Julian of Indiana, the author of the principal bill to sell the minerals lands, was also chairman of the Committee on Public Lands as well as one of the older members of the House. He immediately seized upon the bill and had it referred to the Committee on Public Lands, where he exerted his influence to practically kill the bill through pigeonholing it. He proposed that the bill should not get out of the hands of the committee until his own bill had been discussed and, as he hoped, passed by both branches of Congress. Try as they could, every attempt of the Western members and senators to get the bill out of the hands of the House Committee on Public Lands and before the House met with failure, even though a majority of the committee were favorable to the measure. They were up against a solid stone wall of rule and precedent which they could not breach. Then occurred a piece of clever generalship upon the part of Messrs. Stewart and Conness. Mr. Higby had introduced House of Representatives bill No. 365 in the House and had it reported back from the Committee on Mines and Mining, together with some discussion in the House. The purpose of this bill was by a statutory act to confirm the owners of ditches and canals and the holders of water rights in their possessions under local or district rules and customs. Its purpose was so identical and its interests so inseparable from the subject of mines, that Messrs. Stewart and Conness had included it in the mining bill, though in a different and simplified form. As the way was clear for the House to consider and act on its water-right bill, Mr. Stewart reported the bill to the Senate from the Senate Committee on Public Lands with the recommendation that the entire dual mining and water right bill passed June 28 be substituted by amendment. On July 20 the Senate agreed to the amendment and the mining act took its place as H. R. bill No. 365, 'A bill granting the right of way to ditch and canal owners over the public lands, and for other purposes.' In this form it reached the House on July 21 as having been passed by the Senate with amendments in which the concurrence of the House was requested. At the same time the House Committee on Mines and Mining reported favorably on a bill precisely similar which had been introduced by Mr. Higby on July 16. A majority of the House Committee on Public Lands stood ready to report favorably on the original Senate bill as soon as they would be allowed to do so. The Committee on Territories

had approved the bill. The Commissioner of the General Land Office had given his written recommendation. Messrs. Stewart and Conness had personally labored among the Representatives and had been promised support. Every possible effort had been made to win the final struggle.

The bill came before the House the day after it had been passed by the Senate. When Mr. Julian found that he had been outmaneuvered, he was furious. First he tried to have the bill referred to his Committee on Public Lands, next he tried in every way to block the consideration of the bill, then he attempted to amend the bill by substituting his own to sell the mineral lands. Driven back in each attempt, he finally vented his rage, charging crooked tactics because the fathers of the mining act in the Senate had come to the members of the House of Representatives and asked for help. He said: "It is altogether consistent with the interests of these mining districts that their representatives should zealously labor for this bill, and that honorable gentlemen, not members of this House, should come upon this floor and perambulate these isles as they did on Saturday and are doing today, and tell us to vote for this bill, and command us, in the tone of slave-drivers, to 'Get up, get up, help us, this is a local measure, help us carry it.' Admirably natural and characteristic. But occupying the standpoint that I do outside these mineral districts, and of the contagion of local opinion and feeling and having no other desire than the establishment of a broad and enduring national policy—." At this point he was called to order by a member from Vermont and severely rebuked by the Speaker of the House, who said that senators had a right to come upon the floor of the House to confer with members in regard to legislation and that criticisms and uselessly language against members of the Senatorial body for so doing would not be permitted. Among other things, Mr. Julian said in his argument: "This bill before us hands over the miners everywhere to interminable litigation, discord, and strife. Instead of leading them out of the bondage into which the inaction of the Government had led them, it leaves them to wrestle with their destiny as best they may. That is what the nation will do in remanding this question to the miners as provided for in this bill. And this 'local custom of miners', enacted by 'a corporal's guard' of adventurers, who are here today and gone tomorrow, is to be the basis of a national policy, and the harbinger of peace and order in the mining regions. Instead of extricating this pernicious system, or rather lack of all system, we now propose to set it up as a rule, and coolly ask the nation to conform its policy to it."

Donald C. McRuer, member from California, said:

I wish to say that the proposition to sell the mineral lands did not come from the Pacific coast or from the mineral region. Two years ago we were progressing, as we have progressed for the past seventeen years successfully, to develop the wealth of the country, and possessory titles were considered sound. They were bought and sold with entire confidence and faith in the legislation of this country, the same as titles to real estate were bought and sold. But, sir, since that time there has been introduced into Congress schemes to sell the mineral lands without any regard to the possessory titles. I hold in my hand a bill that was introduced into the Thirty-Eighth Congress, reported from the Committee of Public Lands, which proposes—what? Why, sir, to put up every possessory right within that whole region, and sell it at auction. And the whole logic of that speech and the report made in regard to that measure was, that the people of the mineral regions were a set of vagabonds, and the women were, to a large extent unchaste, and therefore we shall drive out that worthless class of people, sell the mineral lands, and thus attract a meritorious class of people to these regions as settlers. It is in consequence of the apparent encouragement which such a scheme has received here that we now feel that our whole titles are insecure. It has disturbed the faith, it has disturbed the credit, and consequently those who are interested in that region, those who have the interests of that country at heart, have set themselves to work to frame a bill recognizing the possessory rights of all these people.

D. R. Ashley, representative from Nevada, said:

In 1850 it was proposed to legislate upon this subject. A discussion took place in the Senate, but ultimately nothing was done, on the ground that Congress was not sufficiently

informed, and it would therefore leave the people of the mining region to get along as best they could. Accordingly, they were let alone, and for seventeen years they have been going on under their own local rules. Rights of property have grown up. Men have spent seventeen years of their lives there, and invested their property. Their future hopes are all centered in that country. They have considered themselves safe heretofore, and I tell you if we could be sure that the Congress of the United States would never interfere with our occupation of these lands, would never survey and cut them up into square parcels and sell them at auction, we would not come here asking you to dispose of these lands in the manner proposed by this bill, because the local title would be considered safe. We want security. You own your own property here. We ask that the Government of the United States shall give us the same titles to ours. Why should we be lessees and tenants always? Is that the system that the American Government wishes to establish—that all the rest of you may own your own homes, but we who delve in the earth for the precious metals shall be tenants and serfs always?

The bill passed the House on July 23, by agreeing to the amendment of the Senate, there being 73 yeas, 37 nays, and 71 not voting. On July 26, 1866, it became a law through the approval and signature of the President, Andrew Johnson.

THE FIRST MINING ACT

The act of July 26, 1866, entitled 'An act granting the right of way for ditch and canal owners over the public lands, and for other purposes', opens with the section: "That the mineral lands of the Public Domain, both surveyed and unsurveyed, are hereby declared to be free and open to exploration and occupation by all citizens of the United States, and those who have declared their intention to become citizens, subject to such regulations as may be prescribed by law and subject also to the local customs or rules of miners in the several mining districts, so far as the same may not be in conflict with the laws of the United States." It provided that those who had expended \$1000 in labor and improvements upon a lode or quartz claim could obtain a patent therefor at the price of \$5 per acre. That the same was to be obtained through survey by the surveyor-general, and through application to the local land office. It provided that no location should exceed 200 ft. along the vein for each locator, with an additional location for the discoverer of the vein. No person was to make more than one location on the same lode, and not more than 3000 ft. of a lode could be taken in one claim by an association of persons—at this time it was customary for a number of locators to combine their locations into a single general claim. The apex or extralateral right to follow the vein indefinitely on its dip was fully given. It provided that all questions of adverse ownership arising when patent was being asked for, should be settled in the local courts and not in the land office. The section referring to water rights read: "That whenever, by priority of possession, rights to the use of water for mining, agricultural, manufacturing, or other purposes, have vested and accrued, and the same are recognized and acknowledged by the local customs, laws, and decisions of courts the possessors and owners of such vested rights shall be maintained and protected in the same; and the rights of way for the construction of ditches and canals for the purposes aforesaid is hereby acknowledged and confirmed."

The opening section of the act and that on water rights are the two vital features of the act as passed and as subsequently amended. About the first, all our mining law has been built as a matter of detail. The second, without any further national statutory act or legislation, has defined the method of securing water and ditch rights in the West, and is the fundamental authority upon which the states in the Far West control the disposition of water upon the public lands. Both are contained in the present law with a few substitutions of words which have not affected the meaning or interpretation in the slightest.

It is clear that the framers and amenders of the act had as full a knowledge and as wise an insight into each detail as was then possible. Nothing can be clearer from an examination of the debates in Congress, and a consideration of mineral-land history prior to, and subsequently than

that no man, possibly excepting one with a prophetic vision, could have done better, the apex question notwithstanding, as I shall show. For this wisdom, their hard labor, and the Napoleonic shrewdness by which the passage of this act was consummated, the miners of the West owe to Messrs. Stewart and Conness and their co-workers a great debt, one that we seem to have forgotten in these days of disagreement with any thing connected with public-land law. The opening section, and that on water rights was what the miners wanted to a man. They wanted to continue the system of free mining under their own local rules and customs. They were satisfied with them, they believed in them, in the words of Senator Stewart, "The miner's law is a part of the miner's nature. He made it. It is his bantling, and he loves it, trusts it, and obeys it." And in the words of Mr. Ashley, "I tell you if we could be sure that the Congress of the United States would never interfere with our occupation of these lands, would never survey and cut them up into square parcels and sell them at auction, we would not come here asking you to dispose of these lands in the manner proposed by this bill, because the local title would be considered safe." The miners were willing to pay tribute, willing to support the machinery of the Government, they were already paying a tax, but they wanted to secure titles—first, as to possessory rights, and then, as to the fee title through patent. They did not want to be tenants or trespassers, with their fortunes and their years of toil at the mercy of every will-of-wisp of public sentiment, and every irresponsible legislation. They did not want to be the footstool of every demagogue and politician, playing to a temporary popularity by proposing to sell the rich (?) mineral lands of the West to pay the national debt and replenish the federal exchequer—a pleasant and attractive proposition to the great majority in the East who were little concerned with the hardships it would saddle on the small minority in the West.

LODES ALONE CONSIDERED

Though the Western miners were a unit in declaring that Congress should authorize free mining under the local customs and rules, they split in an attempt to go further. The minority could not see how any system of giving the fee title could be put into successful practice. We can now understand why Mr. Stewart and his allies did not attempt to extend the section authorizing the sale of quartz veins or lodes to placer deposits. The lode type of deposit was peculiarly adapted for trying out the new law, which, if found successful, could be extended to other types of deposits and other methods of mining. To have included all types of deposits in the first bill in a comprehensive way, would have made it so involved that Eastern statesmen would have been against it through sheer inability to grasp it—instance the inability of the layman to comprehend the mining law today. For the same reasons a large part of the miners would have thrown their weight against it. Without doubt the passage of an all comprehensive mining act relating to obtaining the fee title would have been delayed for years. The reasons that caused Mr. Stewart to urge the enactment of a means of selling lodes or lode claims to the miners, instead of stopping with confirming the possessory rights were doubtlessly many. He was familiar with the tremendously expensive litigation then going on in the Comstock. The Sutro Tunnel act was about to be passed. The Central Pacific and Union Pacific railroads were rapidly approaching completion. The recent disbandment of the armies of the Civil War was turning westward thousands of men imbued with the restlessness and eagerness for adventure born of camp life. The homestead act was just commencing to populate the West. All these were increasing the importance of quartz mining and giving a new impetus to the development of the West. Agricultural and mineral claimants were rapidly encroaching upon each other, so that the fee title to mining claims and the separation of the agricultural from the mineral land was becoming necessary. The sponsors of the act made it plain that the sale of provisions were to extend only to lode claims; that the bill so far as concerned all other mining

claims was only to perfect their possessory right that they might continue working as heretofore, but with the certain knowledge that they would never be evicted as trespassers.

The idea contained in the act that only those who had expended \$1000 in labor and improvements (reduced to \$500 by the act of 1872) should obtain patent was probably first obtained from the miner's regulations of the Genoa district in Nevada. Hittell in 'Baneroff's Handbook of Mining for the Pacific States', 1861, gives Section 15 of these as follows: "Whenever \$1000 shall have been expended on the claims of a company in this district, the ground so claimed by the company shall be deemed as belonging in fee to the locators thereof, and their assigns; and the same shall not be subject to location or re-location by other parties ever after, except by an acknowledged abandonment by the company of the ground." Hittell makes the following comment regarding this: "In this code are singular clauses, not found in any other mining regulations on the coast. The first peculiar and important feature of this code is that by the expenditure of \$1000 in working a claim, the claimant gets a title beyond all forfeiture. Having spent that amount, he is secure forever in his possessions, against all other miners; but, of course, the code cannot give title as against the federal government, which is the fee-simple owner of the land and minerals. In every other code of mining regulations known to me, the title of mining claims is forfeited whenever the claim is abandoned; and neglect to work for a few days in the season when the claim can be worked, is considered abandonment."

LODE NOT LAND SOLD

One distinguishing feature of this act as exhibited in the wording of the statute, and in the debates in Congress was that it was to give a title to a lode or rather so many feet along a lode, with so much surface ground adjacent as might be necessary—the same to be fixed by local rules—and not give title to an area of land together with all lodes outcropping upon it. The lode or vein was the main thing, and the whole thing with the miner at that time, and the act gave expression to this. The claim was to cover only one lode and no patent was to issue for more than one lode. The rule that no location could claim more than 200 ft. of a lode was in accord with local rules at that time which limited each individual locator to from 100 to 300 ft. along a lode.

Along with the idea that the lode and not surface ground was the main thing, came the apex idea included in the act. Mr. Stewart refers to the apex idea in his speech, and in argument said: "He evidently has not read it [the bill], and has fallen into the popular prejudice of supposing that land is to be sold in rectangular form between perpendicular lines. It has been explained that this cannot be done. A vein pitches into a hill, and a perpendicular line would cut it up into pieces. He speaks of that. This bill provides for selling the vein and following it into the earth, with its natural dips and angles." Mr. Conness also said under argument on this subject: "I desire to say to him, in this connection, that vein mines do not enter the earth by perpendicular lines; but on the contrary, have what are called dips or slants running by oblique lines into the earth; that they follow each other regularly in that respect; and that the custom now, and the habit everywhere, and the law, first determined by necessity, by the fact, next by population obeying that necessity, next by the local courts affirming that necessity by their decisions, is that the miner is authorized to follow every vein according to its dips and angles and variations. This whole bill is based upon the principle of confirming what has grown out of necessity, the wisest system, perhaps, that could possibly be devised, which is the work of the people themselves. Would the senator want to enter the earth by perpendicular lines so that a man who owned a claim today, after he had descended 50 ft. of it, should leave it to the ownership of another man tomorrow."

(To be Continued)

GOLD DEPOSITS of exceptional richness are rumored to have been recently discovered at the Luibavinsky mine, on the river Onon in Siberia, about 200 miles from Chita.

The Institute Debt

By R. W. RAYMOND

*I have scrupulously avoided any connection with the recent contest concerning the management of the Institute. I have never personally favored a change in the name of the Institute, although, if such a change were deemed advisable by a majority of the members, I would not have regarded it as a question worth a fight.

I may also say freely that I have always opposed, except as a last resort, the increase of annual dues; and that I heartily approve the action, taken at the recent annual business meeting, by which this subject has been referred to a committee which is instructed to investigate the economy of the management of the Institute and to report whether such an increase is necessary. In my judgment, it would not be necessary, if the Western American members of the Institute would do their share in lifting the burden of the land-debt incurred by the Institute in its proportional acceptance of Mr. Carnegie's generous gift of \$1,050,000 to pay for the magnificent and perfect building, now occupied by the three national soci-

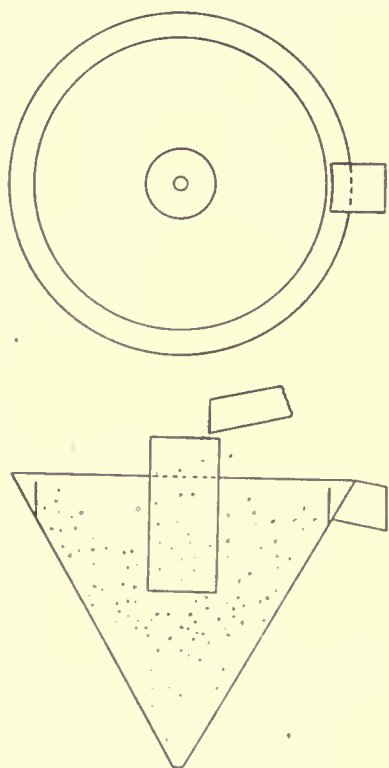

FIG. 1.

eties of Mining, Mechanical, and Electrical Engineers. This benefaction required the three societies to pay for the land on which the building was to be erected; and this obligation, amounting to about \$180,000 for each society, was so adjusted as to be payable in 20 years, with current interest at 4% on the unpaid balance. Into this somewhat perilous obligation the Institute was forced (in spite of my doubts and hesitations as its financial manager, though not against my hopes and aspirations for its assured national and international future) by appeal and pressure of all kinds, culminating in a vote of thanks of the whole membership, of which more than 99 per cent favored the acceptance of the Carnegie gift.

But no sooner had this gift been accepted, and the corresponding obligation assumed, than the very men who had, by their votes, forced this action, began to talk about the Institute as a concern maintained for the benefit of New York members. Now the facilities of our rooms in New

York are enjoyed, as they are intended to be, rather by non-resident than by resident members. The land debt of the Institute has been reduced by voluntary subscription from \$180,000 to less than \$80,000, and I cannot recall a single subscription to this fund coming from any place west of the Rocky Mountains. In fact, 90% of these subscriptions have come from persons in the Eastern states. If the members of the Pacific states would do anything like their share, we could extinguish our land debt, and go on, without increased dues, to expand the operations, especially of our library, so as to make the Institute more valuable to all its members, and chiefly to those who do not reside in or near New York. It is my hope that the investigation committee recently appointed will declare these facts so that they will be understood.

An Improved Cone

By DOUGLAS WATERMAN

Cone classifiers are in general use in cyanide plants to separate sand from slime. The ideal efficiency is attained when the overflow is free from sand. The volume and specific gravity of the pulp determine the size of the

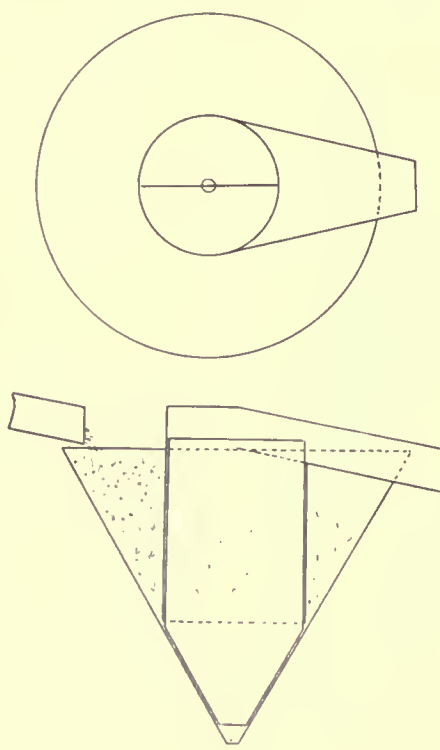

FIG. 2.

cone. It is desirable, in order to save head room, to have the cone as small as possible. Fig. 1 shows the usual form of cone, with a central cylindrical intake and peripheral overflow. Two factors operate to prevent the quiet settlement of the sand. One is the diminished sectional area where the pulp enters the cone, and the other the rapid rise of imprisoned air bubbles.

A simple device, which permits of a great reduction in the size of the cone, was introduced by W. G. Mosher at the Butters San Sebastian mine in Salvador, and has been generally adopted in the Butters plants. At San Sebastian this device has more than doubled the capacity of the cone. This improved cone is shown in Fig. 2. The pulp flows directly into the cone, rises through the central cylinder, and overflows by means of a spout attached thereto. The stream enters the cone at the point of greatest area, where the force of the current is readily dissipated. The rising current in the cylinder is of low velocity and entirely free from air bubbles. The cylinder is divided by a partition extending to near the point of the cone. This prevents the vortex which would otherwise be formed by the discharge of the spigot. The annular space between the side of the cone and the cylinder is $1\frac{1}{2}$ to $5\frac{1}{8}$ inch.

*We are permitted through the courtesy of Dr. Raymond to make public this expression of opinion, originally sent in a private letter. Coming as it does from the long-time leader and manager of the affairs of the Institute, it is of especial importance to all members.—EDITOR.

Chalking of White Lead and Its Prevention

By HENRY A. GARDNER

Chalking and Repainting.—The chalking of white lead is one of the evils attending the use of this valuable white paint pigment which the master painter is most anxious to correct. Every fair observer will probably admit that moderate chalking is not objectionable, as it leaves a surface for repainting which will quickly receive and amalgamate with the new paint applied; this result being difficult with an old painted surface which is excessively hard or brittle. Excessive chalking, however, which is often followed by deep 'alligatoring' and gradual disintegration, should be avoided if possible, for no matter how good a paint may be placed over a deeply-checked surface, the result is always unsatisfactory and unsightly. I have recently read with interest a pamphlet which attempts to explain the cause of chalking that is exhibited by nearly all pure white lead paints after exposure to the elements.

Oil Conservation or Oil Substitution.—It is stated in the pamphlet referred to that the chalking of white lead is due to a lack of linseed oil, and that chalking would not take place to any extent if white lead paints were mixed with greater quantities of linseed oil. From an economical standpoint, it would appear to me that if painters were to follow the above suggestion and use greater quantities of linseed oil than is at present the prevailing practice, the effect would be toward relief from the present high prices which must be paid for pure oil, and might not only encourage the use of linseed oil substitutes which have not been thoroughly tested, but actually lead to the use of such substitutes.

Short Oil and Long Oil Reductions.—It has further been stated that not only the painting coat of white lead but the top coat as well should receive very long oil reductions in order to form a film which would protect the pigment from the elements, which are the initial cause of chalking when lead is applied with the usual short oil reduction. The application of short oil varnishes which contain quantities of gum with very little oil is recommended, assuming that the same enduring results which are obtained on exposure of long oil varnishes would be obtained if lead paints were reduced with quantities of oil. Commenting on the above procedure, it would appear to me that the use of larger quantities of oil than are at present in common use would result in a paint deficient in hiding power and strength. Furthermore, the comparison is faulty in that varnishes consist of gums dissolved in oil; an entirely different material from an oil in which pigments are simply suspended. Both of these materials must be studied along separate lines, as they are physically and chemically different.

Amount of Oil Determined by Pigment.—It is well known that linseed oil, or, in fact, any oil, when spread into a paint forms a coating which upon exposure does not possess any great strength or moisture-excluding power. When linseed oil, however, has been ground with pigments, the strength of the films is increased materially, and the greatest strength is developed in those cases in which a critical percentage varies with the nature of the pigment, a small quantity of some pigments being sufficient, while of others a large quantity is found necessary to produce films of maximum strength. An average paint consists of 10 lb. of pigment suspended in 1 gal. of oil, but I have in mind at present a paint made from 35 lb. of pigment suspended in 1 gal. of oil. This pigment, namely American vermilion (basic chromate of lead), is probably the lowest oil-carrying pigment ever produced or applied under actual practical conditions, and today, after nearly four years' exposure along the Atlantic coast, where it has been subjected to the most severe atmospheric conditions, it is in almost perfect condition, showing absolutely no chalking. Being a lead pigment and being applied with a shorter oil reduction than white lead has been applied with, the result

would seem to dispose of the theory advanced that white lead should be applied with longer oil reductions. If the amount of oil and not the amount of pigment should determine the service of the paint, would not a pigment such as asbestine, which requires enormous quantities of oil, form a paint more durable than white lead or any of the other white base pigments? It is known, however, that this is not wholly the case, and, moreover, the question must be looked at in a practical manner, for the hiding power of a paint is one of the most important properties.

Hydrate and Carbonate.—The percentage of lead carbonate in corroded white lead determines its hiding power, while the percentage of hydrate determines the oil-carrying capacity. When the amount of carbonate runs to 80%, the lead has a high gravity and requires only 3½ gal. of oil to a hundred pounds of paste lead to produce an easy-spreading paint that will have good hiding properties. When the amount of carbonate in corroded white lead drops to 60% and the hydrate reaches 40%, difficulty in grinding is observed, even if additional oil is added. Such a product is likely to harden and become gummy in the package, and upon thinning 100 lb. of paste for application, 6 gal. of oil is required and the product has only slight hiding power. Corroded white lead that contains about 70% lead carbonate and 30% lead hydrate is probably the best grade that can be obtained; its oil absorption is medium and its working properties and hiding power excellent.

Amalgamation.—The claim has been advanced that the application of long oil leads in repainting work is desirable, on account of the penetration into the old paint that can be secured from the newly-applied paint, both amalgamating to form one solid film. If this phenomenon really took place under such conditions, a cross-section of the film produced would probably appear under the microscope as one solid mass of pigment and oil. As a matter of fact, this is not the case.

The Effect of Tints on Durability.—It is very generally admitted that tinted paints are far more durable than white paints. In the article under discussion, the claim is made that the increased durability of tinted paints is due entirely to an increase of oil brought to the white paint by the coloring pigments, all of which have rather high oil-carrying properties. As a matter of fact, however, the amount of oil carried into a white paint by one or two per cent of tinting color is too small for consideration and is insufficient to give the results claimed above. White leads made by various processes take up varying amounts of oil, 100 lb. of some paste leads requiring only 3½ gal. of oil, while in other cases leads made by different processes require as high as 6 gal. of oil to produce paints of the same consistence. Upon exposure of such leads, there seems to be no material difference in the way they wear. This result would further indicate the fallacy of claiming that the extra durability obtained from tinted paints is due to the slight increase of oil brought to them as a contribution from the coloring matter used. The greater durability of tinted paints must be attributed, therefore, to the nature of the added tinting pigments and to the differing physical and chemical properties which they bring to the white base.

Carbonate and Oxide Pigments.—The carbonate pigments, such as lead carbonate, calcium carbonate, and barium carbonate, will all chalk when painted out and exposed to the elements. This chalking seems to be a distinct feature of the carbonate pigments. While it is true that certain other pigments which are not carbonates chalk quite heavily, it is furthermore true that the exception proves the rule. Pigments which are not carbonates, but which have other radicals, and which will probably be more readily recognized if called by their trade names, such as red lead, zinc white, litharge, etc., do not possess chalking tendencies, and they form paints which remain hard and glossy under long exposure. When either carbonate pigments or oxide pigments are reduced with short or long oil reductions, the same conditions hold true. It would become at once apparent, therefore, that if the chalking tendencies of the carbonate pigments are to be overcome and corrected, or the excessive

hardness of the oxide pigments is to be reduced, a mixture of the two in the correct proportions should solve the problem. As a matter of fact, mixtures of this type do not become excessively hard, nor do they chalk to any great extent, and, although this principle was long ago discovered and has been used for years by progressive painters, it must be stated over and over again in order to convince those who are not thoroughly familiar with the results of paint tests.

Conclusions.—After considering the present practice of some of the leading members of the association, and summing up the results obtained from practical tests made throughout the country, I have formed the conclusion that the paint best suited to withstand service is a tinted paint made of a proper mixture of pigments, carefully ground together and applied by a painter, for even the best paint made must be applied by skilful hands, guided by intelligence, if the best results are to be obtained.

The Nature of Sherardizing

By A. R. JOHNSON and W. R. WOOLRICH

*It is now about a decade since Sherard Cowper-Coles made the discovery, quite by accident, that if a piece of metal, like iron, for example, is buried in zinc-dust, and the mass heated out of contact with air, there is deposited on the iron a beautiful coat of zinc. The process was given the trade name 'sherardizing.' While the commercial application of the process appears to have been slow at first, it nevertheless grew steadily in favor for certain kinds of goods, and, after getting a firm hold in England, appears to be spreading rapidly in the United States.

The close attention which this process is attracting may be due largely to the simplicity of the process and to the mystery surrounding the actual nature of the deposition, but, as we believe, is due more largely to the very great value of the coating as a protective agent for iron and steel goods. Any process that brings engineers and chemists one step nearer the solution of this so important problem in the realm of the conservation of building materials must surely attract the most serious attention. With this fact in mind, we present some results gleaned from a rather broad industrial research on zinc cementizing, which we hope are of sufficient scientific value to be of general interest. In working the process of sherardizing, whether for commercial or scientific ends, we must know the amount of zinc deposit as a function of the following factors: temperature, time, concentration of zinc-dust in inert powder, and size of zinc particles. No doubt, much of such information has been obtained, but it does not appear to have been published as definite data.

As in most physical and chemical processes, so in the case of sherardizing metals, the temperature factor is of extreme importance, and therefore many carefully arranged experiments were carried out to determine the rate of deposition of zinc not only upon iron, but also upon nickel, brass, copper, and zinc. Evidence is clear that not all metals, even those much less electropositive than zinc, sherardize with the same degree of readiness. Copper, as might be surmised, receives a coat of zinc much more readily than the other metals. The authors have produced coats on copper ranging from a mere film of yellow brass to a pure white of remarkable smoothness. Pure nickel sherardizes more readily than iron. A rod of pure zinc, polished until perfectly smooth, did not start to sherardize to any considerable extent until a few degrees below its melting point. Yellow brass receives a coat readily, but not so readily as does copper, and the curve has a somewhat different trend. But of the greatest interest is the fact that all the curves approach the same rate of deposition with rise of temperature, and the limiting value lies at about the melting point of zinc. From this point on, the depo-

sition of zinc becomes exceedingly rapid. The range of temperature between the point where the first appreciable deposit occurs to the melting point of zinc may be looked upon as the true sherardizing range of temperature for a particular metal. This range is greater for copper than for iron.

One of the most surprising facts found in our study of sherardizing is the pronounced effect the fineness of the zinc particles has on the rate of deposition and smoothness of the zinc coat. The finer the zinc particles the smoother and apparently more penetrating the zinc coat. But the finest of zinc-dust will not deposit as fast at a given temperature as a relatively coarse zinc-dust of 150 to 100-mesh. Results were obtained which showed nearly twice as rapid deposition of zinc at 370°C., in three hours, from 150 to 100-mesh zinc, as from the finest zinc-dust. The coat is quite rough for the coarser dust, however. For commercial work, a proper medium between smooth penetrating coats, slowly deposited, on the one hand, and rough thick coats, quickly deposited, on the other, might be struck. Coarse zinc-dust is much less satisfactory in other respects when used alone than fine zinc-dust, for it yields but little hydrogen when heated, and the voids are so large as to allow air to penetrate the mass to considerable depths and oxidize both the sample receiving a coat and the particles of zinc, often to such an extent as to destroy the sherardizing. Besides, there is a great tendency for the coarser material to fuse together. It is, therefore, necessary to use some impalpably fine inert powder with such so-called 'finely-divided zinc' to at least partly fill the voids.

Our explanation or theory of the sherardizing process is as follows: In the light of the phase-rule the iron, zinc, and vapor may be regarded as forming a closed system, all parts of which are practically at the same temperature. Zinc, compared with iron and most other metals, has a relatively high vapor tension. Zinc alloys fairly readily with many of the common metals like iron, nickel, and copper. When the process is ready to be started, the iron, for instance, is surrounded and in intimate contact with many particles of zinc. Under the influence of heat these particles, carrying their slight atmospheres of zinc vapor, form a superficial alloy with iron. This superficial alloy on the iron would very likely be a solid solution of zinc very rich in iron. Now we may look upon the iron with its insignificant vapor pressure as greatly lowering the very appreciable vapor pressure of the zinc which is forming a solid solution with it, and we should expect the zinc vapor to distil from the points of higher tension to the place of low vapor tension at the surface of the iron-zinc alloy. As the iron alloy grows richer and richer in zinc under the process of sublimation or distillation, its vapor tension will gradually approach the tension of the vapor of pure zinc particles, and hence the process gradually ceases.

The experimental facts already presented show that the nature of the metal to be sherardized, having reference to its alloying properties with zinc, has a great influence on the temperature at which sherardizing will start and its rapidity after starting. That we did not succeed after several trials in depositing zinc on a pure rod buried in zinc-dust is also in accord with our theory. Also, pieces of iron which had once received a coat of zinc of considerable thickness refused to sherardize at any such rate as fresh iron at temperatures below the melting point of zinc. However, if the coat of zinc already present is thin, the deposition will start again, though more or less tardily.

New lines for experimentation are suggested by this theory which should at the same time test its validity. Sherardizing should be greatly retarded if the finely-divided zinc used were a solid solution with some metal of low vapor tension, as iron, nickel, or copper. If the vapor tension of the metal to be deposited is lowered until about equal to that of the most saturated solution possible on the surface of the metal being sherardized, the process should not take place, or only to a slight extent. Furthermore, any substance which would impair or change the initial alloying tendencies of the metals should also greatly influence the process.

*Part of a paper presented at the meeting of the American Electrochemical Society, in Boston, Mass., April 18 to 20, 1912.

Lead Production in 1911

By C. E. SIEBENTHAL

*This advance statement is designed to afford at the earliest practicable date authentic figures of the production of lead in the United States in 1911. The figures of production are based on confidential reports by each lead smelting and refining company in operation in the United States during the year. The figures of imports and exports are taken from the records of the Bureau of Statistics of the Department of Commerce and Labor, and those for 1911, not having been finally checked, are subject to minor revision. The cordial coöperation of each lead-smelting company is acknowledged with keen appreciation. In explanation of the tables below, it should be said that the refined-lead product cannot be apportioned according to source of ore, owing to the fact that lead refiners treat smelted products whose origin may, as in custom refining, be unknown to them, the identity of the ore, and thus its original source, being preserved only as far as the smelter. Accordingly, the table showing source of lead smelted or refined in the United States is based on smelter figures. It includes pig lead reported by all smelters using Mississippi Valley soft lead ores and lead produced at all other lead smelters in this country. A part of the product reported by smelters operated in conjunction with refineries is in terms of refined lead. A like part of the antimonial lead product is thus eliminated from the 'lead' produced and appears only in the figures of production of antimonial lead. No lead ore from the United States was treated elsewhere during the period covered by the table.

The statement of the production of refined primary lead embraces all desilverized lead produced at works in this country and the pig lead recovered from Mississippi Valley soft lead ores. The pig lead derived from Mississippi Valley ores and desilverized is shown separately. The antimonial lead reported by refineries is also given. The original source of the ore and bullion affording this refined product is shown in detail in the accompanying table showing primary lead smelted or refined in the United States. In the table showing consumption, 'lead' includes all kinds—lead in ore, base bullion, pigs, bars, and old. The figures of domestic production are based upon returns by the smelters; all other figures are from the records of the Bureau of Statistics. Decrease by liquidation covers losses in smelting and refining in bond and other corrections. Warehouse stocks of bonded lead of foreign origin are given, but it has been found impossible to obtain complete figures of domestic stocks. For this reason the result is given as 'lead available for consumption.' The 'apparent consumption' of previous reports would be this quantity increased or diminished by the increase or decrease of domestic stocks during the year. The table showing the world's production of lead has been recalculated to short tons from the statistics published by the Metallgesellschaft, except those for the production in the United States.

² Subject to revision.

FERRO-TUNGSTEN can be produced in electric furnaces with a power consumption of 4000 kilowatt-hours per ton of metal. At Luton, the power is supplied from the corporation power-station at 500 volts direct current, and is converted into alternating current of low voltage by means of a motor-generator set provided with suitable regulating devices. Three large furnaces are operated alternately, thus utilizing the full power of the plant, and it is proposed to erect two more furnaces, each of about three times the capacity of the present ones. The ore is ground in a ball-mill, mixed with the reducing agent and flux in the desired proportions, and fed into the furnaces. After the smelting is completed, the resulting blocks of metal, weighing 6 to 8 hundredweight (hundredweight = 112 lb.), are lifted out by means of a crane and broken into large lumps, which are subsequently cleaned, broken into walnut size, and sorted ready for the market. Trials are also being made with other high-grade alloys, such as ferro-uranium and ferro-tantalum.

A REVIVAL during 1912 is predicted for the North Coolgardie field, Western Australia, which produced 60,270 oz. last year, and did not fall far short of the previous year's output of 60,887 oz. The chief mine of this field, the Menzies Consolidated, maintained its yield well during the year, and is looking as good as ever. Numerous small outcrops at Tampa and elsewhere have been taken up by small companies or syndicates, prospecting work has been fairly active, and the field begins this year with better prospects than last.

Discussion

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Insertion of any contribution is determined by its probable interest to the readers of this journal.

Government Bureaus and Potash

The Editor:

Sir—In the issue of March 30 of the *Mining and Scientific Press* I find an editorial on the subject of 'Government Bureaus and Potash.' I have no desire to enter into a controversy, but the wording of your article and the mis-statements contained in it call for an emphatic reply.

At the outset I wish it understood that I assume full responsibility for the press bulletin on Borax Lake. The Bureau of Soils coöperated with the Geological Survey in the search for potash, and F. K. Cameron of that Bureau participated in the preparation of the press bulletin in question to the extent that it met his approval as prepared; the first page of the bulletin containing some facts which failed to please you was written by myself except so far as the wording of the telegram from the field was adopted.

I am glad that you admit that it is highly proper for the Bureaus in question to undertake to discover potash salts within the boundaries of the United States. Considering that special appropriations had been made by Congress for this purpose, it was not only proper but imperative for these Bureaus to undertake this task. The method of investigation and the publication of the results were left to the discretion of the Bureau chiefs, who have followed their best judgment. Congress wisely did not request them to follow the guidance of the press or of private parties who themselves were investigating the subject. While I regret that you think our method of publication "a disgrace," I fail to understand what method you would have recommended. Possibly you would have preferred to have the Geological Survey preserve silence until the matter had been fully covered in detail by the preparation and publication by the Survey of a well illustrated professional paper and the "private parties" could have had an opportunity to ascertain the extent and location of similar deposits, if such exist? As I see it, it is beyond question the duty of the Geological Survey to publish important data of this kind at the time when they are needed and not several years afterward. Truly you are hard to please: in one issue the Geological Survey is scolded for dilatoriness in its publications and in another for publishing the results too soon.

Your complaint is, it appears, that the press bulletin on Borax Lake contains sensational statements and not accurate information. You attack the bulletin as "disgraceful" in its estimate of the amount of potash in Searles lake, and with more experience in mine sampling than in the evaluation of brines you ridicule the assertion that a great tonnage of potash salts are here available. Permit me to say that I am still of the opinion that the estimate of four million tons of potash is conservative and that probably the supply is much greater. If in a uniform area of lake basin of eleven square miles six wells are sunk at widely distributed points and yield practically the same results in percentage of potash down to a depth of 60 feet, I consider that there was full justification for the assumption of uniformity throughout. In these salt marshes there is unquestionably a sufficiently free movement of brine through the mass to give a high degree of uniformity in content of potassium salts, which are among the most soluble of those in solution. You refer to such reasoning as "facile leaps"; I would call it good logic.

You question whether the data given are accurate. Your acquaintance with the Geological Survey might have led you to assume that they would not have been issued unless reliable. As a matter of fact, control analyses were made

at the Survey laboratory in Portland. The statements as to the tonnage and availability of the supply of potash were issued as a *preliminary bulletin* and to furnish the people with information at the earliest possible moment. You will find in almost every sentence qualifying words indicating that the results are not final—the concluding sentence of the first page that, "at any rate it appears that this locality constitutes a very important source of potash in probably readily available commercial form," goes to make the press statement no more conclusive than we believed then and believe now the facts warrant.

You are evidently not aware of the exact facts in the discovery of potash at Borax lake. The deposits have been worked for borax and prospected extensively for soda by several different parties. All of this prospecting had been for the purpose of testing the brines and salines for sodium salts. No tests for potash were made. More recently some of the interested parties had three analyses made for potash on composite samples made up from old residue material on hand in the laboratory. Only one of these showed any appreciable amount of potash and it was questioned by the parties themselves whether the analysis was reliable. To the best of my belief this was the only scrap of exact information available to anyone interested in the Borax lake, until March 5 when the representatives of the Geological Survey and the Bureau of Soils jointly visited the locality and took careful samples of the brines from the six wells. While therefore the presence of potash was known before the visits of the Government men, Messrs. Gale and Free, the results of the analyses of the six samples was the first positive information available as to the exact amount and the uniformity of the contents of potash, even to the owners or proprietors of the Borax lake.

Your final accusation of "self advertisement" by Government bureaus is hardly supported by the fact that the Geological Survey is mentioned only twice in the offending bulletin in connection with the potash of Borax lake, but it leads me to inquire just how you would prefer to have a Federal bureau make authoritative announcement of information which it believes of public interest and benefit? I am not a little puzzled by your request for information as to the potash minerals in the brine. The potassium compounds are present in water solution, and if you will inquire from chemists you will find that with a mixture of salts in solution your query cannot be answered. In conclusion, I maintain that the Geological Survey was fully warranted in issuing the press bulletin of which you complain; that it has acted for the best interest of the people; that the facts are correct, and that future development will probably justify my position.

GEO. OTIS SMITH.

Washington, D. C., April 9.

[Our primary objection to the press bulletin criticized is the sensational form of the statement; secondarily, we question the accuracy of the estimates. No careful reader of the *Mining and Scientific Press* can have any doubt of our approval of promptness in publication on the part of the Survey. Indeed, among the excellent things that the present Director has accomplished, few rank higher in our estimation than the speeding up of the whole organization and particularly the decrease in lapse of time between field work and publication. While Presidential messages based on telegrams from field assistants may suggest an undignified scramble, we would not argue for dignity as against results. Neither have we any predilection for pretty reports or for elaborate, time-consuming illustrations. Prompt publication of reports that are simply and clearly written and which contain such illustrations as the circumstances demand, are what is desired by all the good wishers of the Geological Survey, among whom we claim a place. Our objection to sensationalism in a particular press bulletin can not fairly be interpreted as a criticism of the series or of promptness in publication. Surely there is no real confusion on this point.

In our judgment the particular bulletin to which objec-

tion was made was sensational and misleading in two particulars. In the first place, it announced as a "discovery" something that was previously well known to a considerable number of people, to most if not all of those concerned; in the second place, there was no suggestion of the fact that the lands concerned are not open to location but are already covered either by patent or location.

Searles lake or Borax lake has been known, as is stated in the original bulletin, for many years. It has been repeatedly investigated by engineers and chemists, and chemical works are now in existence on its borders. Borings have been made, at private expense, and much is known (as also much is unknown) about the content of the lake or *playa*, as it is better called. The samples taken by the Survey officials must have come from wells put down and owned by private parties. We are informed that the official had a blueprint showing the position of these wells, and probably also one showing the results of previous tests for salts other than those for potash. Scant recognition of all this previous work, which cost thousands of dollars, appears in the Survey bulletin. Furthermore, the Director is evidently not aware of the exact facts in the discovery of potash at Borax lake. It is true that potash was not taken into account at the time the original sampling was done, but its presence had been discovered some months ago. It is also true that many more than "three analyses" had been made, and it is not true that "only one of these showed any appreciable amount of potash and it was questioned by the parties themselves whether the analysis was reliable." As to these matters, the Survey officials were evidently not completely informed. So well established was the fact that potash was present, that negotiations have been conducted in New York for the sale of the property, and in fixing the price the probable value of the potash entered. Presumably the Survey officials knew, or could have known before visiting the property, that potash had been found there. Their observations are confirmatory, but they do not amount to a discovery—and the difference is large in advertising value.

In the second place, the bulletin was misleading in that there was no suggestion that the lands concerned are, in the eyes of the courts, if not on the records of the Land Office, private lands. Some of the land has been patented and the remainder is held by location; the very wells from which samples presumably were taken, were put down in performing annual labor on the claims. The California Trona Co., in particular, has large holdings, and its title was considered sufficiently good to warrant the Foreign Mining Development Co. in advancing considerable sums of money, foreclosed by a mortgage, which, it happens, was recently foreclosed. A locator has about as much chance to secure a share of this newly "discovered" potash as he has to file on part of the White House lot. Yet the bulletin was written in such terms that a stampede to the district resulted. We do not see that there is any public benefit in producing such a result, and much individual hardship is sure to follow.

Aside from the Sunday supplement style of the announcement, there is a question as to the accuracy of the figures furnished by the Survey. An estimate that ranges from 4,000,000 to 10,000,000 can not be very exact at best. Into its making entered (a) the accuracy and uniformity of the samples and analyses; (b) the salinity of the brine; (c) the percentage of brine in the salt body; (d) the area covered by the sampling. We have no question as to the accuracy of the analytical work, and it is stated that results indicate that the brine is nearly uniform throughout the flat—which statements of fact are accepted without question. Other sampling and analyses, however, give lower results both as to content of potassium and salinity of the brine. The latter is necessarily related to rainfall. The assumption that the salt body contains 25% by volume of brine, is necessarily arbitrary. It may be right or it may be wrong. There are no data available for checking or controverting it, but on its accuracy the whole estimate stands or falls. It is known that the solid salts, principally sodium chloride and sodium

carbonate, vary greatly in purity and distribution throughout the lake, and also that the structure of the rock mass, if that term be applied to the body of crystalline salts, also varies through a wide range. Presumably its porosity does the same, and it is an open question how much brine there is in the lake; a question that, so far as we know, has never been tested thoroughly by pumping. There may be as much potash in the lake as is estimated by the Survey—there may, indeed, be much more—but we do not believe that the available data warrant any such estimate on the part of a technical bureau supported by the Government, an organization that should deserve and have a reputation for the highest accuracy. The estimates would be in place in "the prospectus of an irresponsible promoter", and despite the qualifying phrases upon which the Director insists, the public will be fortunate if they are not widely used in such literature.

There is still another question involved. The potassium, as the Director suggests, is in solution in the brine and while in that condition can not be considered to be in any particular combination. It is important, none the less, to know the form of combination in which it occurs before going into solution, and especially the form in which it can be recovered. While data on these points are not complete, they point to the occurrence of the potassium as a chloride. It happens that this is the less easily available form. For use in fertilizer, which must be the main market, the sulphate is preferred; particularly in the Western states where fertilizer is in demand mainly for sugar-producing crops or fruit. A process for converting the chloride to the sulphate has been devised, but it increases the cost of the finished product and is an important obstacle to development. There is plenty of aluminum in clay, but practically it is not commercially available. The potash as chloride is by no means as unavailable as the aluminum, but there is point, none the less, in the analogy, and this point has been commonly overlooked in discussion of the potash situation. The attempt to obtain potash from Pacific Coast kelp is proving disappointing for this among many other reasons. There are many conditions connected with trade organization which make it certain that the development of a profitable potash industry in the United States is for the present improbable. Announcements of discoveries so worded as to lead to stampedes to the desert and to promotion of potash companies are, therefore, harmful rather than helpful. Eventually we hope to see the United States independent in the matter of potash supply. There will be ample time before this occurs to permit the Survey to prepare a most elaborate report, even if there is not time before Congress adjourns. In brief, we consider the offending bulletin to have been better calculated to influence Congressional opinion favorably in the matter of appropriations than to help development of an American potash industry, and we regret to see the Survey resort to such means for justifying its work.—EDITOR.]

The Mine-Owners' Liability for Accidents.

The Editor:

Sir—The new order of dealing with the problem of industrial accidents which had, as I have shown in my preceding letters, been evolving out of chaotic conditions for the better part of a century, was first given authoritative and general application in Germany in 1884 at the instance of Bismarck as a paternalistic counter-movement to the Socialistic proposals of the Social Democrats. The substance of Bismarck's economic creed was this: "Every able-bodied worker in Germany is an asset of the Fatherland and it behooves the Fatherland to take good care of him to the end that his toil may make the Fatherland rich."

Germany has done this better than any other nation, and for that reason Germany has become industrially the most efficient nation on the globe, and 'made in Germany' has become a household saying the world over. At first German employers protested that Bismarck's policy would bankrupt them and, especially, that it would shut them out of

the markets of the world, inasmuch as their commodities would have to meet in the open market the commodities of other countries in which the cost of industrial accidents was thrown upon the workers instead of upon the employers. Bismarck told them not to worry; that the nation that took the best care of its workers would prove the most efficient, and therefore the cheapest, producer. It was so, and today German products compete successfully with British in all the markets of the world. All of continental Europe soon saw the beneficial results of Germany's experiment, and made haste to follow Germany's example.

Great Britain also saw, but hesitated to undertake compulsory insurance, as Germany had done, for the reason that British genius and inheritance do not so well lend themselves to compulsion as to persuasive and permissive methods, reinforced by individualistic initiative. Nevertheless, British sentiment had long ago resented the heartless doctrines of Lord Abinger and Parliament had greatly modified them, but still made negligence the basis of claim until 1897, when compensation without regard to negligence was made compulsory as to certain hazardous occupations. The new order was extended in 1900 to cover farmers, and, in 1907, to cover all employers in Great Britain. Nearly all of the British colonies have followed the example of the mother-country. Insurance is not made compulsory, as on the continent of Europe, but compensation is compulsory as to all employers, if not as to all employees.

The United States, deriving its laws mainly from the Common Law of England, and not, as on continental Europe, from the Civil Law of Rome, has followed the British example as to compensation for industrial accidents with the exception that employers are afforded the right of a choice between a reformed law, of liability, still based on negligence, and compensation without regard to negligence. This has been done because the courts have taken to themselves powers of nullification of legislative acts, on grounds of unconstitutionality, that no court in Great Britain has power to exercise in relation to any act of Parliament; the authority of Parliament, and not that of the courts, being the supreme law of that land. Nothing in this country becomes compulsory that a united public sentiment does not force upon Congress, legislatures, and courts alike, and public sentiment has not, in this state and country, as yet become sufficiently educated to the need for, and justice of, compensation to justify compulsory measures.

Therefore the new order in this country, including California, mainly consists in abolishing the infamous old common-law defenses of assumption of risk and fellow-servant, and in the modification of the doctrine of contributory negligence to a doctrine of comparative negligence, under which injuries will be recompensed in damages in proportion to the degrees of negligence which employer and the injured person respectively contribute to the injury. This new order is supplemented with an optional compensation system, without regard to negligence, which the employer may or may not operate under, as he chooses. Every employer of labor in California must do business under one or the other of these two laws, liability in damages for negligence or liability for compensation without regard to negligence. No other country gives the employer any such power of electing what law he will do business under. In all countries where the compensation theory has been adopted in lieu of the negligence theory, the employer is bound absolutely. In Great Britain the employer is bound, but the employee is not. In that country the employee may, after he has been injured, elect whether he will proceed against his employer, first, for damages under the common law, with the old common-law defenses about as they were when Lord Abinger laid them down, or under the employers' liability law of 1897, which greatly modified those defenses, or, finally, under the compensation law without regard to negligence, as provided by the statute of 1907. But so satisfactory is compensation, with its limited payments, that during 1910, out of, in round numbers, 282,000 accident claims only 217 cases were carried into the courts outside the compensation law.

The abrogation and modification of these old defenses by

the first two sections of the Roseberry law have probably increased the liability of employers in damages for such accidents as occur to their employees, three or four times over. In other words, instead of having to pay damages for injuries in only 8 to 12% of the actions brought against them they will probably have to pay damages in 25 to 50% of all such cases. Furthermore, the tendency in suits for damages is for juries to come closer year by year to allowing the claimant all that he has lost, including payment for pain and suffering and disfigurement, as well as for loss of earning power for the rest of his life. The value of an industrial life has been rated ridiculously low by courts and juries, but the sums assessed in damages have doubled within ten years, although they will probably have to double again before reaching a parity with the losses suffered by those who are hurt.

It may be of interest to note, just here, how actuaries estimate the value of a life as a basis for annuity insurance. A man of 21 years, in good health, is estimated as having a capitalized value of \$6303 for each dollar-per-day of wages earned; a man of 30 years is set down at \$5883 for each dollar-per-day; at 40, \$5235; at 50 he still has a value of \$359 for each dollar-per-day of earning power, and at 60 he is worth \$3309. Even at 70 he is rated at \$2244. These figures are based upon actuarial mortality tables of long standing and are used to compute the present value of annuities, and, taking into account, as they do, the uncertainties of life, afford a very good standard for measuring the monetary loss to a family of the life of a breadwinner. A miner who earns \$3 per day would have a capitalized value to his dependents of three times the figures above quoted for the ages given. If ever courts and juries resort to such tables for computing damages as insurance companies use for computing the value of lives there will be such a rush of employers to get under compensation with its limited liabilities as will give the compensation provisions of the Roseberry law all the efficacy of a compulsory statute, and the trend of events is unmistakably in that direction. In my next letter I will set forth the four-fold justification of compensation, as a principle to be applied to the settlement of claims for industrial accidents as contrasted with the negligence theory of adjustment.

A. J. PILLSBURY.

San Francisco, March 25.

THE U. S. Geological Survey's estimates of the coal areas of Texas show that the bituminous fields known to contain workable coal cover 8200 sq. mi., and that 5300 sq. mi., not so well known, may contain workable coal. The known lignite areas cover 2000 sq. mi., and there are 53,000 sq. mi., extending from Sabine and Red rivers on the east and north to the Rio Grande on the southwest, which may contain workable beds of lignite. The estimated original supply of bituminous coal in Texas is placed at 8,000,000,000 short tons and of lignite at 23,000,000,000 tons, making a total of 31,000,000,000 tons as the original supply. From this there had been mined to the close of 1910 a total of 20,956,941 short tons, which represents an exhaustion of approximately 30,000,000 tons, the exhaustion being one-tenth of 1% of the original supply. The supply left in the ground at the close of 1910 would be equal to 19,000 times the production of that year.

MAMMOTH COPPER Co., of Klondyke, Queensland, is engaged in the preliminary work of smelter construction. The following are the principal mines under control of the company: Chieftain (working), Allen, Koeppeck, Lochinvar, Ladrone, Lamington, Noonday (working), and Mountain Maid. The erection of the smelter will be an inducement to other owners in the district to develop their claims.

ORE shipped from Norwegian ports will hereafter be weighed by public weighers, who at the request of shippers will weigh or control the weighing of ores for export, and for each shipment will furnish a certificate of weight to accompany the ship's papers.

Special Correspondence

NEW YORK

MEXICAN DEVELOPMENT AT A STANDSTILL.—PORCUPINE ISSUES DISCARDED.—COPPER SITUATION.—COMPANY NOTES.

The mining situation in Eastern financial centres, particularly in New York, is a peculiar one. There is not at this time any mining district in process of exploitation in which any part of the market public is interested. A very large share of the mining activities in New York is curtailed by reason of existing conditions in Mexico. Mining men who have recently returned from the other side of the Rio Grande are apparently a unit in declaring that intervention is the last thing that is wanted. On the other hand, intervention appears to be the next important move on the program. New Yorkers are told that American mining properties in places such as Guanajuato, Pachuca, El Oro, and similar centres have been turned into fortified camps and provisioned with rations, arms, and ammunition to withstand long sieges. Naturally, under such conditions there cannot be any steps taken in the development of new enterprises.

The formal opening of the mill of the Dome property at Poreupine was an event which passed without exciting any comment. The destruction of the power-plant by fire marred the celebration a little, but damage was repaired in time to proceed without interruption. The market followers have almost entirely discarded Poreupine issues, and so far as New York is concerned, the district can hardly be said to be now on the map.

Sixteen-cent copper is having a reviving effect upon many of the producers that have lain idle for a time. The old Santa Fé Gold & Copper M. Co., with properties in Santa Fé county, New Mexico, is to be once more placed on a producing basis if present plans mature. The property is equipped with a small smelter, to be blown in during the present summer. The property is capable of a production of 3,000,000 lb. copper per year at a cost of 11c. per pound. This property is a subsidiary of the General Development Co. Granby made up some of the ground which it lost a year and a half or more ago when it made its sensational drop in price, and scored a rise of about ten points on its improved prospects. A rumor was at once started that dividends were to be resumed, but this is authoritatively denied by officials of the company. There has been a great improvement in conditions at both the Grand Forks property and the Hidden Creek ground. The old property is now earning about \$100,000 per month net, while the conditions at Hidden Creek justify an estimate of a production of 30,000,000 lb. per year, at an 8c. cost within the next two years. Granby is one of the older properties that is due for a new and vigorous lease of life under the stimulus of 16c. copper. At present the company is spending about \$20,000 per month in the development of the Hidden Creek property. Plans for a smelter are for the present held in abeyance, but it is realized that before the Hidden Creek property is brought up to its full capacity the question of a smelter must be determined. The improved outlook in copper has had its effect upon even such issues as Ohio Copper, in which the trading has reached a fairly respectable volume recently in New York. The reports from the property are not altogether encouraging. A. E. Wall has been handling the mill; the tonnage being treated, and the results obtained are said not to be by any means satisfactory. Ohio Copper is one of the porphyries that ought to show great improvement if it ever comes into its own.

The annual report of the Nipissing Mines Co. has just been issued; the most interesting item being the production of 5,197,042 oz. silver at a cost of 13.95c. per ounce. This cost compares with 14.71c. in 1910 and 16.39c. in 1909.

A special meeting of the Guggenheim Exploration Co.

has been called for April 17 to authorize a division of the present stock issue into shares of \$25 par value. This will not change the outstanding stock of the company, but will simply give the shares a lower denomination, so that trading will be easier to handle. The Guggenheim Exploration is to be listed on the New York Stock Exchange and will undoubtedly be one of the market favorites. The Greene-Cananea management is considering plans to alter the par value of its stock, with the idea of reducing the number of shares from 2,500,000 to 1,000,000.

Shareholders of the Utah Consolidated are feeling somewhat discouraged. This is one of the copper properties that has not been rejuvenated. The annual report recently

MEXICO MINES OF EL ORO.

put out shows less than one year's supply of ore in sight, and unless future developments are much more favorable than those shown during the past year, the end of operations is apparently close at hand.

BOSTON

PRODUCERS' REPORT ENCOURAGES BULLS.—MAYFLOWER AND OLD COLONY 'GUESSING CONTEST.'—BOSTON INTEREST IN GRANBY.

The Copper Producers' statement, made public April 9, supplied an additional bull feature to the copper-share market. It had been predicted in Boston that the statement would show about a stand-off between production and deliveries. A further decrease in the supply of 572,431 lb. was favorably construed by market interests. Boston believes that the surplus of 62,327,557 lb. as of April 1 has reached as low an ebb as is desirable for the healthy maintenance of the copper industry. This surplus is the smallest amount reported since the Copper Producers' Association was formed and began to give its monthly statistics. With a record output of steel, with which copper travels as a companion, and the extraordinary foreign demand for copper, Boston is of the opinion that the metal will hold its rise, subject to the ordinary ebb and flow, for some time to come. Copper has sold higher than 16c. in Boston, and predictions are freely made that 18c. will be reached in the near future.

Boston is being treated to something of a guessing contest on both Mayflower and Old Colony. Anonymous letters have been circulated freely for the special purpose of boosting Old Colony, asking the question whether it is not as cheap as Mayflower. Almost before the No. 14 drill had got fairly started, the news was wired here that Old Colony had found the Mayflower lode. The facts were that it had not had time to find anything. It is not likely that the lode will be encountered above 800 ft. depth. Mayflower has its No. 18 drill down over 700 ft., with about 600 ft. more to go, which will take until the latter part of April. Mayflower recently sold at 17¾. Old Colony has not yet reached its high price of 21½.

made in 1909. It has about 10 points to go yet in that direction. These stocks are still very closely held, within a few hands, this being especially true of Mayflower, and the putting up of prices has been an easy matter.

The recent interest in Granby's market revival is natural in Boston, since Boston got in early in Granby's promotion a few years ago. The Granby management expects to start building this spring the proposed new smelter at Goose Bay, B. C., where it will treat northern British Columbia and southeastern Alaska custom ores. The Hidden Creek property, recently acquired by the Granby, is being put in condition for production during 1913. It is expected that the new property will produce around 30,000,000 lb. copper at a cost of not over 8c. per pound, with combined output of the new and old properties around 50,000,000 lb. at a cost of 8½c. per pound. The new smelter is to be built for custom purposes and to treat the Hidden Creek ore. Granby's market improvement is due to work getting under way at the old property and 16c. copper. There is some talk of an early resumption of Granby dividends, but this is denied.

PIOCHE, NEVADA

EARLY HISTORY OF THE DISTRICT.—W. S. GODBE'S WORK.—

EFFECT OF RAILROAD FAILURE.—LEADERSHIP OF E. R. WOOLLEY.

Since the Salt Lake railroad was washed into the Pacific Ocean on January 1, 1910, no one at a distance from Pioche could gather satisfactory and conclusive information about the district from any of the ordinary sources of publicity. Certain officials of a great corporation, whose interests are closely interlinked with those of the district, gave interviews apparently intended to induce a belief that Pioche had proved a failure. Spasmodically certain brokers in various cities wasted much good paper and ink in telling of wonderful impending developments which never developed. Lawyers were much in evidence and, however it might be with others, they were continuously 'working' the district for profit. Only recently has there been a prospect so definite that a prudent man could have been justified in making plans, as based upon reasonable certainty. So many changes have taken place here in corporate ownership and control that a brief review of the salient facts in Pioche history is essential to a lucid understanding of present conditions and probabilities.

Mining began here in 1868, when Pioche was three hundred miles from the only railroad in the West, with scarcely a hundred white neighbors in a hundred miles. The heaviest producing mines were owned by the Raymond & Ely M. Co. and the Meadow Valley M. Co. The banner year was 1872, when three companies distributed nearly \$3,000,000 in dividends. The ore was milled at Bullionville, twelve miles distant, where at one time practically a hundred stamps were in continuous operation. Water was met at a depth of 1200 ft. in 1874, and near the water-level the character of the ore changed and it could no longer be treated by amalgamation. In 1876 the light flickered for a few months, and finally went out.

In the eighties and early nineties W. S. Godbe, a man of remarkable energy and ability, and with strong backing, made heroic efforts to revive the district, but in 1892 misfortune befell the U. P. R. R. Co., which had graded to within sight of the town, and compelled that company to abandon its plans for Pioche. Coma followed for twelve years.

In 1894 the best of all the old properties were gathered together by the Nevada-Utah Mines & Smelters Corporation. This company also included in this district the Day mine, on this side of Bristol mountain, fourteen miles northwest of Pioche, the narrow-gauge railroad leading to it from the Pioche depot of the Salt Lake, thirty-two mile branch line, and certain disconnected properties in the region, more or less in the prospect stage. About that time the mines on the farther side of Bristol mountain, sixteen miles distant, were gathered together under the corporate control of the

Bristol Consolidated M. & S. Co. The Bristol mountain mines on both sides of the range were very rich, and for many years yielded large amounts. When the Godbe campaign collapsed, these mines also went into enforced repose. W. S. Godbe died, leaving three sons, who always held the district in the same esteem as their father had done. They obtained, through their father's estate, a half interest in the Pioche Water Co., which is a very valuable asset, because it is the town's only source of water supply. This they held jointly with the Nevada-Utah, and also certain valuable mining property.

In 1906 they began to develop the Susan Duster mine, then a recent discovery, owned by the Ohio Kentucky M. Co. In this virgin ground they opened an enormous deposit of silver-lead-zinc ore, similar to the ore of the Black Ledge, to be referred to again. Later the Ohio-Kentucky M. Co. took over another old property, with similar ore, which had not been secured by the Nevada-Utah. But the great achievement of the Godbes consisted in opening an early-day mine, rechristened the Prince, under the corporate ownership of the Prince Con. M. Co., which was controlled by them. Just before the railroad went out, the Prince mine, at an expense exceeding \$30,000, was exhaustively examined by an engineer of national reputation, and a tonnage running into the millions disclosed of the most desirable fluxing iron-manganese-silver-lead ore ever known in the West.

Negotiations for acquiring control of the Prince in the interest of the U. S. S. R. & M. Co. were nearing completion when arrested by the destruction of the railroad, which caused them to be abandoned. For half a year the engine and passenger coach left here by the receding floods remained chained to the track. A little desultory work was done and a few ears of ore shipped. The most important prerequisite to satisfactory activity was a spur track to the Prince mine, a distance of eight and three-fourths miles. Its fluxing ores were of too low grade to stand wagon haul for that distance. Its vertical and bedded veins of silicious ore, while sufficient in themselves to make a great mine, could be worked with proper economy only in conjunction with the fluxing ore. With this spur once built, there could be no doubt about the outcome for both the railroad and the district. But railroads cost money. The Prince treasury had been exhausted in opening the mine, previous to the disaster. At the conclusion of its period of 'innocuous desuetude' the railroad resumed its old train schedule, soon changed this to semi-weekly, and as if with a fateful purpose to destroy the district, immediately reduced that to weekly. All who could escape fled precipitately.

Such were the conditions when Ernest R. Woolley, of Salt Lake City, suddenly came into the limelight as the controlling factor in Pioche affairs. A professional promoter, with limited means of his own, and without any large backing that was ever disclosed, the announcement was suddenly made that he had secured control of the Nevada-Utah and been elected its president. The Nevada-Utah Mines & Smelters Corporation, with its 1,500,000 shares, distributed among 8000 shareholders, had for years been a football of mining speculators. With a par value of \$10, Thomas W. Lawson, shortly before the panic of 1907, during one of his characteristic campaigns, ran the shares up to \$8, giving the property a nominal market value of \$12,000,000 and filling its treasury with a handsome development fund. When Woolley was elected president this fund had been virtually dissipated by injudicious methods and the company's affairs were in a precarious condition. He, however, appointed Harry C. Parker superintendent, and work was resumed on the Day mine, which soon began producing 50 tons per day, and this output was gradually increased to 100 tons. At about the same time work was resumed on the No. 1 mine of the Consolidated Pioche M. Co., a corporate name which had been given to a former consolidation of certain conflicting interests of the Nevada-Utah and Ohio-Kentucky. This work was pushed to a junction with the old Raymond & Ely 1200-ft. level and resulted in finding the old Black Ledge, a

lead-silver vein opened by the Raymond & Ely in the '70s. H. H. Day, manager of the Raymond & Ely, believed it would restore that company to great prosperity. W. S. Godbe explored it to the 1500-ft. level and found it so promising that, largely because of it, he persuaded the Union Pacific railroad management to start building to Pioche. The meteoric Woolley regime, its conclusion and results, make a story of absorbing interest, which must be deferred to another letter, as must also the story of how the Prince Con. M. Co. found a way out, and why it is today constructing its own railroad to the Prince mine.

JOHANNESBURG, TRANSVAAL

DIFFERENT PHASES OF THE EAST RAND PROPRIETARY MINES AFFAIRS DISCUSSED.

After all, there was no struggle for the control of the East Rand Proprietary mines, a compromise having been mutually arranged between Sir George Farrar and the Central Mining & Investment Corporation. This arrangement was fully endorsed by the shareholders at the annual meeting, the majority of whom fully recognized the past services of Sir George, the principal founder of the company, as far outweighing any advantages likely to be gained at this late hour by the change of control of the company's affairs. It is quite true that many shareholders were somewhat disappointed at the apparent shrinkage in the ore reserves after so much prominence had been given at the previous annual meeting to the excess development, but it is not difficult to see that this shrinkage is more apparent than real. Those who are thoroughly acquainted with the property will know that Ross Skinner's report shows all the bad features it can and fails to recognize any encouraging feature the mines may seem to possess. When this is properly understood neither Mr. Skinner nor Mr. Anderson, the acting general manager, can be blamed, for the lower they can base the start the more will be the aggregate success they can show. Nevertheless, while the property in parts has bad prospects, there are some good points about which even the shareholders should know. It was disappointing that Mr. Skinner, when appealed to at the meeting of the shareholders, did not on the spot refute the figures given by one shareholder that this huge property had an estimated life of only ten years. Then again it seems due to the shareholders that when they are told of the water feeders likely to be found when the water-dike is intersected they should also be made acquainted with the fact that wherever this water-dike has been cut, sufficient improvement in ore has always been found to more than pay for the extra cost of pumping. No one will attempt to justify the sending of waste rock to the mill or abnormal quantities of low-grade ore, but in such a property of varied ore grades as that of the East Rand Proprietary Mines, where many million tons run close to the profitable grade, it frequently becomes necessary to work low-grade ore to get at one of better grade. Such a well equipped property as the East Rand must be worked and handled in a liberal manner. There is also something to be said in the case of the East Rand Proprietary Mines as regards large-scale working and bringing down working costs so as not only to maintain the recent profits but to mine many million tons of ore which at a fair working cost would be profitable.

The prevailing opinion here is that Messrs. Skinner and Anderson have, not unwisely perhaps, represented the property at its worst, so as to make it all the easier to earn credit for the results bound to follow the adoption of a good, sound, and straightforward method of mining. The recent disclosures in connection with the East Rand Proprietary Mines with regard to the calculation of tonnage milled continue to cause discussion. It does not seem to be generally known that the method of arriving at the tonnage milled is, with very few exceptions, on the Rand a loose one. At not a few mines it is based on results or even merely guessed. No wonder need be expressed that at the East Rand Proprietary Mines, where so many irregularities existed in the late administration, the manipulation

of the tonnage milled should be regarded as of small importance. Those who have had any experience outside of the Rand will know that, were it desired, absolute accuracy could be obtained.

A writer in a local mining paper professes to be incapable of understanding Mr. Skinner's explanation for the apparent increased costs of working during the latter end of 1911. He suggests that the mine manager would be 'emancipated' by the adoption of the idea of working profit for work-cost as a means of comparison of efficiency. It is quite clear from Mr. Skinner's report that the working costs at the East Rand Proprietary Mines have been apparently increased, or, perhaps it would be better to say, brought to their proper level by more accurate calculation of the tonnage milled through not using a too small unit of measurement, and also by charging the whole mining cost to that instead of to the development capital account. It is clear that the new policy of calculating the working cost must have a double-barreled effect, by decreasing the tonnage estimated to be milled through adopting a correct unit of measurement, and thereby creating a smaller division, and charging the full mining expense to revenue. The plan of 'emancipating' the mine manager by adopting the profit for cost as a means of comparison is generally recognized on the Rand, but not perhaps in the sense I have suggested. During the past six months as many managers have been 'emancipated' because they failed to produce the expected profits. It was this race after profits that delayed and intensified the clean-up at the East Rand Proprietary Mines.

BLACK HILLS, SOUTH DAKOTA

NEW ASSAY SCHEDULE.—MOGUL TO REBUILD MILL.—HOMESTAKE REPORT.

A new schedule of prices for ore-assays has been put into effect by the United States assay office, at Deadwood. An assay for gold and silver will be made for \$1, and iron, lead, zinc, tin, and copper will be determined for \$1 each. It is stated that this is the only Government office where this price has been made effective, and it will no doubt be liberally patronized. Formerly \$3 was charged for an assay for gold and silver. The insurance companies have made a satisfactory adjustment with the Mogul company for the damage sustained by the recent fire at that company's cyanide mill, and as soon as the money is paid over the work of rebuilding will be started. A sweeping decree in favor of the defendant, in a case brought in Detroit, Michigan, clears up the Golden Crest situation to a marked degree. In the suit a stockholder sued for an accounting of the money spent on the property. He wanted to know what had become of \$750,000. Mr. Bailie, president of the company, was able to explain the matter fully, and in addition to finding for the defendant, the court also ordered a large amount of stock and two large notes cancelled. This leaves the company with only a small bond issue and a judgment for \$125,000. It is understood that the money is in sight to pay the judgment and resume work. The property is one of the best equipped in the Black Hills, having a 40-stamp mill, a tube-mill, and a Moore filter. Everything about the property is in excellent shape, and it should be one of the most economically operated in the country. The shaft is 300 ft. deep and shows a large body of milling ore. The mill has never been operated, and it seems to justify the old saying, 'a good mine must be tested by litigation.'

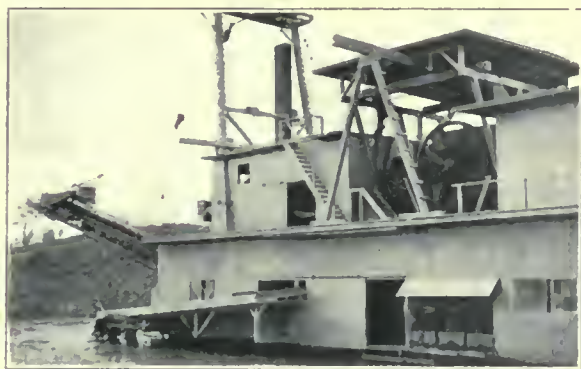

The Homestake M. Co. has issued a report covering nineteen months' operation, from June 1, 1910, to December 31, 1911. The fiscal year of the company being changed to conform to the calendar year caused the company to hold back the report for the past fiscal year. The report shows the following for the year ended June 1, 1911: Ore milled, 1,468,263 tons; recovery, \$5,251,454; per ton, \$3.5766; dividends, \$1,310,400; hydro-electric plant expenditure, \$393,088; net loss, \$397,537. For the seven months ended December 31, 1911: Ore milled, 888,057 tons; recovery, \$3,661,152; per ton, \$4.1205; dividends, \$764,400; hydro-electric plant expenditure, \$231,134; surplus, \$414,261.

There is broken in the stopes 1,883,277 tons, and there is enough blocked out and unbroken ore to supply the 1000 stamps for twenty years. A recent development of fluorite in the property of the Echo G. M. Co., at Maitland, is causing much discussion. The body is an inch to a foot in width, and carries a little gold. It is near a phonolite dike, and work is under way to explore its junction with the dike. Should it follow the Cripple Creek precedents, a body of high-grade ore may be developed.

LONDON

PLANS OF THE SOUTH AMERICAN COPPER SYNDICATE.—OROVILLE DREDGING REPORT.—PATO PLACER MINES.

I have referred briefly to the reopening of the Aroa copper mine in Venezuela. Further particulars of recent output and intentions are now at hand. The South American Copper Syndicate was formed in 1907 for the purpose of reopening this group of copper mines, which is situated on the Barquisimeto railway, fifty-five miles from the port of Tucacas, Venezuela. These mines have been known since

DREDGING AT OROVILLE.

the sixteenth century, and from 1882 to 1894 were worked by an English company, the Quebrada Railway, Land & Copper Co. From 1887 to 1894, over half a million tons of ore averaging $8\frac{1}{2}\%$ copper was mined. In the latter year the workings collapsed, owing to inefficient provision for the support of the overburden. At the time, the price of copper was exceptionally low, so that it was impossible to raise the necessary capital required to recover the mine. The present syndicate acquired the property, after it had been inspected by George Grant Francis, and the reopening has been conducted under the management of W. J. C. Scrutton. The capital of the syndicate is £7500. The amount of cash spent in purchase and development has been £19,950; while £20,625 has been distributed in dividends. The shipment of ore to Europe to December 31 last totaled 31,674 tons, averaging $9\frac{3}{4}\%$ copper and yielding 2674 tons of metal. Since the first of the year 4200 tons has been shipped. The directors plan a rearrangement of the capitalization and the raising of £75,000 working capital for the purpose of extending development and providing metallurgical plant.

Last year the Oroville Dredging Co. promised earlier publication of results than hitherto. However, the report for the year ended July 31, 1911, has just made its appearance. As the relations of the English and American Oroville companies and of the English company operating as a subsidiary in Colombia are complicated, it is advisable to give a résumé. The American Oroville company was formed in 1905 to consolidate a number of gold-dredging companies operating in California. As a large proportion of the shares are held in England, a new company was registered in England in 1909 to acquire the shares in the American company and eventually to take over the direct management. As the exchange of shares is not complete, owing to some American holders declining the offer, the American company is still in existence and is responsible for the management. Another step has been the formation of the Pato Mines (Colombia), Ltd., under English law, to

acquire gold placers of that name in Colombia, South America, the working capital of which was supplied on loan by the American Oroville company. The report of the American Oroville company for the year ended July 31, 1911, has now been published. As regards the operations in California, 4,433,262 cu. yd. was dredged, yielding gold worth \$462,286, at an expense of \$261,832, leaving a profit of \$200,454. The figures per cubic yard were: revenue 10.42c., cost 5.90c., and profit 4.52c. The yield per cubic yard was 0.5c. less than the year before, and the cost was 1.81c. greater. The figures relating to output and cost for the previous year were: Cubic yards treated, 5,661,612; yield, \$561,569; and profit, \$275,452. The decrease this year has been due partly to fewer dredges being in operation and partly to a decrease in the content in one part of the property. The profitable ground left to be treated is sufficient to last for five years. Repairs and improvements in the Oroville plant have been suspended until no further funds are wanted at Pato. As regards the latter property, the expenses have been greater than expected, owing chiefly to the cost of the dam. Up to July 31, 1911, \$534,129 had been advanced by the American Oroville company to the Pato company, and until the Pato property becomes a producer, no dividends can be paid to the shareholders in the American and English Oroville companies.

AUSTIN, TEXAS

NEW CONCENTRATOR FOR VAN HORN DISTRICT.—TERLINGUA RAILROAD HALTED.—QUICKSILVER PRODUCTION.

Activity in the Van Horn district, west of here, shows a decided revival. The most notable improvement is that of the Hazel M. Co., which is erecting a new concentrating plant at the Hazel mine near Van Horn at a cost of \$50,000. Charles A. Cutler, of Dallas, is a heavy stockholder of the company. For several years this property was a large producer of rich copper and silver ore. Operation was suspended a few years ago, but recently development was resumed, and it is stated that a large amount of good ore is now blocked. When the concentrating plant is finished about three hundred men will be employed by the company, it is announced. The improvement which this company is making is causing much attention to be turned to the Van Horn district by prospectors, and a number of claims have been located recently. Several old mines which have been closed for some time will be opened.

The receivership of the Kansas City, Mexico & Orient railroad has caused a temporary suspension of the construction of that road through the district between Alpine and the proposed crossing of the Rio Grande. A. E. Stilwell and associates planned to run a branch line from a point about thirty miles south of here to the Terlingua quicksilver district, but it is now considered doubtful if this road will be built. There is said to be a prospect of the Pecos Valley Southern railroad being constructed through Alpine and thence south to either Terlingua or Boquillas. The territory in Mexico just opposite Boquillas is known to be rich in minerals and a few mines have been opened in that region, but owing to their inaccessibility comparatively little in the way of development has been done.

W. P. Gaines, of Austin, recently organized a company of New York men, in which B. F. Yoakum, chairman of the Frisco board, is interested. The company has taken over a large tract of mineral land in the Terlingua district. Some prospecting has been done. Several outcroppings of rich cinnabar ore have been found. Preparations are being made to develop the property. The value of the quicksilver output of the Chisos M. Co. at Terlingua has averaged about \$15,000 per month for several years. The ore is said to be increasing in richness as the depth of the workings becomes greater. Recently new and rich bodies of cinnabar were found in the mine. Several new claims have been opened recently in the Shafter district. A large number of Americans who were prospecting in Mexico at the time revolutionary disturbances began in that country have gone into the district recently and are said to be meeting with success in finding veins of silver.

General Mining News

ALASKA

PRINCE WILLIAM SOUND

The Cliff mine, says a Valdez report, in March produced \$36,000. The last shipment, amounting to \$10,000, was made from the mine March 31. A compressor and pump have been ordered, in preparation for developing deeper levels. Ray Millard, who has been superintendent since the operation was started, has resigned his position.

THE TANANA

Reports from Dawson state that the Guggenheims are planning to start extensive dredging operations in the Tanana. The Yukon Gold Co.'s No. 1 Bucyrus dredge, which has been operated on Hunker creek, near Dawson, has been dismantled, preparatory to removal to Fairbanks.

Mining has been started on the creeks near Fairbanks, Eglar, Howe & Peterson, laymen on the upper 800 ft. of the Abe Lincoln Association, sank three shafts 60 ft. to bed-rock, and found ore assaying as high as 50c. per pan.

ARIZONA

COCHISE COUNTY

A report from Willecox says that the Calumet & Arizona company has bought from J. N. Kinney his contract with

per, which makes it profitable to mine ore of lower grade. The concreting of the Kingdon shaft at the United Globe mine has been completed for 305 ft. below the collar. The third section has been started at a depth of 525 feet.

L. D. McClure, managing director, and H. E. Dunn, manager for the South Live Oak Development Co., are superintending work preparatory to exploring, by churn-drilling, the Schultze group of 16 claims southwest of and adjoining the Southwestern Miami. At the Five Points mine of the Manitou Copper Co., eight miles west of Miami, the Cracker Jim shaft caved in last week, burying, under 20 ft. of rock and timbers, Henry Peryam, a miner, who was rescued alive and unhurt after four days and nights. The Miami Copper Co. is mining and concentrating 3000 tons of ore per day and the mill is reported to be doing excellent work. Experiments are being made in the sixth unit with a roughing system, with a view to increasing the efficiency of the crushing department. Emil Deister, formerly of the Deister Concentrator Co., has erected one of his new six-decked slime-treating machines below the first unit.

Globe, April 11.

MARICOPA COUNTY

Reports from Wickenburg state that the Old York mine is to be unwatered. Thomas Williams is in charge of the property. Work will be resumed also at the Yarnell, where a small force is now preparing for actual production.

MOHAVE COUNTY

Ore said to assay 70% tungstic acid and to be the richest tungsten ore in the United States, is being mined at the Williams property in the Big Sandy district. Kingman reports say that a mill will be built soon on the property to handle the low-grade ore. Seeley W. Mudd represented the investors who recently took over the mines. Ralph Bulkley has obtained rich tungsten ore from his property north of the Williams mine. The C. & O. Development Co. mill is reported to be ready for operation. The Tom Reed shipped a 5705-oz. bar of silver bullion, valued at \$70,000, to the mint as the result of its monthly clean-up.

The Shooting Star mine, Stockton hill, soon will make shipments to the smelter, according to a statement by Robert Gray, owner of the property. The Shooting Star vein contains gold, silver, lead, zinc, and copper. Thomas Gray is in charge of the mine. Development has been carried on for the last six months. It is rumored that the annual meeting of the Tom Reed company, to be held soon, will result in plans for enlarging the mill. Charles Grimes, president of the company, states that a larger output than ever before is being made by the mill.

CALIFORNIA

ELDORADO COUNTY

(Special Correspondence.)—The Crane's gulch quartz property, near Placerville, has been purchased by H. D. Jerrett and brothers. It is said to have a recorded output of \$175,000. The owners state work will immediately commence, and, if satisfactory, a mill will be built. The Placerville Gold Mines Co. is planning deep development of its holdings in the Placerville district. The company controls the Pacific, Excelsior, and other noted mines. It is reported the main shaft at the Pacific will be deepened to determine the nature of the ore deposits. British capitalists are interested. A. Baring-Gould is manager. The New Linden Gravel M. Co. has been incorporated to operate the Alderson mine, recently taken under bond. The property lies in Cedar ravine. The company is capitalized at \$100,000, par value of stock \$100. D. David, of San Francisco, and J. F. Owen and L. N. Stickler, of Placerville, are the incorporators. It is reported Plumas capitalists have resumed operations at the Cora Dora mine, adjoining the Mt. Pleasant in the Grizzly Flat district. Arrangements are under way for the reopening of the Union mine, near El Dorado. It is planned to sink to a sufficient depth to explore the ground lying beneath the barren belt.

Placerville, April 15.

ARIZONA.

the Commonwealth company for the old tailing dump at that property. The Calumet & Arizona company uses the tailing for converter linings, and formerly obtained it through Kinney.

GILA COUNTY

(Special Correspondence.)—The March production of the Old Dominion smelter was 2,412,000 lb. fine copper, of which about 95% was derived from ore from the Old Dominion and United Globe properties, the rest coming from enstom ores. A contract has recently been let to the El Paso Foundry & Machine Co. for the construction of a separate flue and dust chamber for the converter plant. Plans are being prepared for the enlargement of the present concentrator 50%, and the classification and mill work are to be improved. The payroll has been considerably increased during the past three months until at the present time the number of men working, including lessees, is about 1200. While the production shows a considerable increase over the February production, the tonnage mined was much greater, owing to the higher price of cop-

MARIPOSA COUNTY

(Special Correspondence.)—The Poehonta's copper mine, at Lewis, will resume operation and shipment of ore, according to a recent announcement by David Ross, superintendent of the property.

Lewis, April 16.

SISKIYOU COUNTY

(Special Correspondence.)—The Michigan Salmon M. Co. is operating its placers with an elevator. A good deposit of gold-bearing gravel has been opened and a profitable season is expected, provided the water-supply proves sufficient. The holdings are at the mouth of Know-Nothing creek. L. E. Tagget is superintendent. The Bennett company is operating with a full crew on the Crapo and Forks of Salmon claims. Sufficient water has been developed to operate three giants. It is stated that recent developments on the Crapo have been particularly satisfactory. The company has leased its Bloomer claim to Wilson & McLaine, and the Nigger Hill claim to Gorham McNeil. The Bennett properties are situated in the Salmon river district. B. McNeil has taken a lease on the McNeil claim, owned by the Nordheimer M. Co. Sufficient water is stored to keep the giants active until the end of June. Hydraulic mining throughout the county is in full blast, and indications are favorable for a fairly prosperous year. It is reported interests identified with the Siskiyou Syndicate are endeavoring to consolidate several small properties in the Happy Camp district. Bradshar & Wyrick report the cutting of a good quartz vein about two miles from the forks of Salmon river. The vein is stated to be three to five feet wide and has been driven on about 125 ft. Sluicing is about to start at the Indian Flat placers. The Minnetti B. ditch and flume system has been completed to the claims, and abundant water is available. The properties are owned by the Siskiyou Mines Company.

Yreka, April 14.

TRINITY COUNTY

Press reports state that the Craig M. Co. will build a mill on its property at Dedrick.

COLORADO

CLEAR CREEK COUNTY

(Special Correspondence.)—Advices concerning the transfer of the Colorado Central mine on Leavenworth mountain to Henry B. Clifford & Co. of New York are to the effect that work will be started within 60 days. The plant will be situated at Georgetown, and an aerial tramway will be constructed. In the Lost Treasure mine, on Columbia mountain, a streak of ore 8 in. wide has been uncovered that mills 582 oz. silver and 40% lead per ton. The discovery was made 215 ft. from the portal of the adit. William Kramer is owner. Work will be resumed in a few days on the Homestake property. The adit will be driven ahead with machine-drills. A. L. Stephens is manager. At the Ohio property, on Bard creek, a 15-in. streak of \$60 gold-silver ore was cut. More ore is going out from the Capital mine than at any previous time, the estimated production being \$80,000 per month. E. C. Bauman is manager. Work will be started at the Waldorf mines during the next 30 days. C. L. Tingle is superintendent.

Georgetown, April 10.

GUNNISON COUNTY

The Forest Queen shaft will be unwatered and sunk 200 ft. deeper. It is reported that the owners of the Sylvanite mine will resume operation soon. The property is in the Crested Butte district.

LAKE COUNTY

The experimental mill at the Helena property has been completed, and will be started soon. A rich streak of ore was cut recently on the 230-ft. level. During March the Wolfstone property produced 12,000 tons of ore; the Yak, 11,000 tons; the Iron-Silver, about 4,000 tons; the Ibex, 7,000 tons, and the South Evans about 6,000 tons. Outlying portions of the district will be more active than for several years past, say reports from Leadville.

OURAY COUNTY

The Brown Mountain Smelting Co., of Ouray, has completed the purchase of the Hill smelter from J. M. Tenney, of Methuen, Massachusetts. The smelter will be ready for operation, according to present plans, by June 15.

SAN MIGUEL COUNTY

The Junta Gold Mines Co. has awarded O. M. Sackett a contract for a tramway from the Junta mine, in Junta basin, to the Bear Creek mill, on which the company has a ten-year lease. There will be a curve-station at the Jim Crow group of mines. A shortage of ore has caused the shut-down of the Pandora mill. It is said that the agitating-tanks at the Smuggler-Union, at Pandora, will not be in operation before July 1, unless the railroad uses more speed in delivering the steel. Rich ore was found recently at the San Bernardo property, at Matterhorn.

TELLER COUNTY (CRIPPLE CREEK)

The El Paso shaft has been sunk to the level of the Roosevelt deep-drainage adit. The deepening of the shaft was accomplished by driving a raise, which for the 328 ft. accomplished cost about \$10 per foot, a saving of \$7.50 as compared with the expense of sinking.

The Kavanagh cyanide plant has a new crusher, installed at a cost of about \$1000. It is rumored that the operators in the Beacon hill part of the district may establish a mine-rescue station on account of difficulty caused by accumulations of gas.

Mail advices state that the sump of the Golden Cycle shaft, which is 1650 ft. deep, is dry. The present flow necessitates pumping 450 gallons of water per minute throughout the 24 hours. The Progressive M. & L. Co., a Denver company, has secured a long-term lease on the Chickenhawk mine, Guyot hill, and will sink the shaft to the 1100-ft. level.

IDAHO

SHOSHONE COUNTY

(Special Correspondence.)—The Federal M. & S. Co. at the Morning mine is reported to be making \$3500 per month since tube-concentrators were set up. A duplicate of the present plant has been ordered.

Wallace, April 15.

Four years reserve supply of ore has been blocked out on the 900 and 1200-ft. levels at the Hecla mine in the Coeur d'Alene district, according to a report by James F. McCarthy, president and manager, at a meeting of stockholders of the company in Spokane. There is also a small reserve on the 600-ft. level. The plan is to keep the development work ahead of production. The company paid \$100,000 in dividends during the five months ended December 31, making total net earnings of \$2,370,000 at that time.

The Hypotheek M. & M. Co., operating in the Wallace district, plans to enlarge its mill equipment, set up an electric hoist, and obtain other supplies. To meet the expense, an assessment of five mills was levied at a recent meeting of the directors, when the officers were reelected. George V. Harrington, former manager, has been made vice-president, and P. F. Rogers, former superintendent, becomes manager. The Culvor Mining Co., operating the Amy and Matchless on Pine creek, in the Coeur d'Alene district, under bond, has acquired the crusher, jigs, and other milling apparatus formerly used at the old Antimony mine near the Amy.

MONTANA

LINCOLN COUNTY

(Special Correspondence.) A. M. Balfour states that the Blacktail property was damaged during the winter by a snowslide which came down the side of the mountain and wrecked a portion of the mill. The damage will not prevent operation, however, although some delay will be caused. Mr. Balfour thinks that the plant can be operated by June 1. The Blacktail is a gold property in the West Fisher district.

Libby, April 15.

SILVERBOW COUNTY

(Special Correspondence.)—The first move in bringing to trial the suit of the Anaconda Copper M. Co. against the Butte-Ballaklava came up a few days ago when a motion was made on behalf of the defendant for a transfer of the case to the federal court. The judge took the matter under advisement. In another week the Leonard mine, which has been closed down since the first of the year, will again be in operation.

In the course of development on the 500-ft. level of the Ophir mine of the Butte Central Copper Co., a fine body of copper ore about 8 ft. wide, and containing $2\frac{1}{2}$ to 3% of the red metal, has been cut. The Pilot Butte company has commenced sinking its shaft from the 900-ft. level to explore at depth for some of the rich copper veins which are supposed to extend from adjoining mines. Recently on the 900-ft. level a rich body of zinc ore was cut. After many demonstrations the Butte & Superior company has decided to construct, near the new concentrator, a one-unit plant for testing the Peterson process of zinc smelting. It will be ready in about ten days or two weeks. P. E. Peterson, the inventor of the process, claims that he can save 95% of the zinc, 95% of the copper and gold, and 70 to 95% of the silver. The copper, silver, and gold is to be saved in the form of a matte. The Butte-Alex Scott is now shipping 200 tons of ore per day to the East Butte smelter, which is just about the capacity of the equipment. Samuel Newhouse, of Salt Lake City, has become interested in the Madison district through coming into possession of the Revenue mine by foreclosure. This mine has been a fine producer in the past, and mining men declare that under modern methods it can be made a profitable mine. The San Francisco men who have secured possession of the Gold Coin property in the Rochester district will start operation in a few days on a large scale. New equipment has been installed and the property can be worked at depth. There is much ore on hand awaiting treatment. A new orebody is reported to have been opened on the 2600-ft. level of the North Butte, but official confirmation cannot be obtained. The work of cutting through from the 2800-ft. level of the High Ore to the North Butte to afford ventilation on that level is well under way, but five or six weeks will be required before the work is completed. The work of lengthening one of the furnaces of the East Butte smelter will be completed in June, and there will be as little delay as possible in extending the other one.

Butte, April 13.

NEVADA

CHURCHILL COUNTY

(Special Correspondence.)—Work was resumed on April 15 in the mill of the Nevada Wonder M. Co., after a shut-down of three months, due to shortage of electric power. No trouble was experienced in starting, and the mill has been operating smoothly since the power was turned on. During the shut-down some repairs and improvements were made which have bettered the operation of the mill, and changes are now under way which will increase its capacity and efficiency. These alterations will consist principally of changing from intermittent agitation to continuous agitation and placing another Dorr thickener ahead of the filters. By these alterations, it is expected to improve the already good rate of extraction and to balance the capacity of the different units so that the mill will be able to handle its rated capacity of 100 tons per day with the best results. The necessary machinery has been ordered. During the period of enforced idleness at the mill, development was continued at the mine. The two-compartment shaft was sunk from the 500-ft. level to the 715-ft. point. The last 115 ft. of the sinking was done at the rate of 6 ft. per day with three shifts at a cost of \$26.31 per foot. Driving was carried on at several points and considerable ore was opened up on the 400 and 500-ft. levels. The property is in much better shape than it was when the power was shut off.

Wonder, April 16.

CLARK COUNTY

Reports from Searchlight say that operation has been

resumed at the Johnnie M. & M. Co.'s property, of which Miles S. Gregory is manager. The mill will be started in the near future. A 12-ft. vein was cut recently on the 300-ft. level of the Rand mine, formerly known as

JOHNNIE M. & M. CO. MINE.

the Black Hawk, in Eldorado canyon. The ore is said to run about \$35 per ton. Robert Dunbar, the principal owner, is in charge of the property.

ELKO COUNTY

The U. S. Geological Survey has just issued a 162-page bulletin, No. 497, entitled 'A Reconnaissance of the Jarbidge, Contact, and Elk Mountain Mining Districts.' The work is by F. C. Shrader. In addition to giving a geological description of the districts, and other purely scientific information, a short history of their development, and lists of the principal properties are given. The bulletin can be obtained on request from the U. S. Geological Survey, Department of the Interior, Washington.

ESMERALDA COUNTY

A deep shaft will be sunk soon on the Sandstorm-Kendall Con. property. The old Kendall shaft will be used to prospect both properties in depth.

HUMBOLDT COUNTY

(Special Correspondence.)—The National Mines Co. has temporarily suspended milling mine ore, pending the crushing of about 3000 tons on the old Stahl dumps. Much of this assays about \$125 per ton and the mill is treating 30 tons per day. It is handled for the owners of the old lease on a royalty basis. The high-grade quartz is separated from the ordinary ore and stored in an underground vault. Exploration is being done at the Mammoth National claim, but mining is prevented by the litigation between the National and Workman interests. It is reported the Arizona mine, near Unionville, will be shortly placed in operation. C. S. Floyd has obtained a five years extension on his lease on the Harnan property, near Erlach. The 4-ft. vein is lead-silver, and has some iron and a little gold. Arrangements have been made for the erection of a concentration plant, including three sets of rolls, three tables, two vanners, and other equipment. The capacity is to be 50 tons. It is expected to complete the plant by July 1.

Winnemucca, April 13.

NYE COUNTY

Efforts are being made toward a reorganization of the old Tonopah Golden Crown M. Co., a Utah corporation. In a statement to stockholders in the old corporation, they are reminded that the company was formed in 1905, and operation was continued through sale of the stock, which was non-assessable, and when this source of revenue was closed, through funds advanced by four directors, W. H. Dickson, C. K. McCornick, Ernest Bamberger, and A. C. Ellis, Jr. When the loans and interest had reached about \$55,000, a judgment against the company was secured, and at a sheriff's sale these directors purchased the property. Since the sale, in March 1911, the directors claim to have expended in assessment work, taxes, and patenting, \$1442. The company had six months from March 21, 1911, to redeem the property. The directors now offer the

stockholders the property on payment of both sums named, aggregating \$61,229, or as an alternative submit a plan for reorganization on an assessable basis. The new company would be capitalized at \$1,500,000, with shares \$1 each. Of this, 500,000 shares would be set aside to pay the indebtedness referred to, 500,000 shares would be put in the treasury, as working capital, 450,000 shares would be used for exchange for stock of the old company, on a basis of one share of new for two of old stock, and 50,000 shares would be used for promotion purposes.

The Tonopah M. Co. in March milled 14,706 tons of ore, and shipped 260,600 oz. gold and silver bullion, valued at \$206,650. One hundred tons of concentrate, valued at \$44,700, was shipped. The net profit for the month is announced as \$150,940. The Tonopah-Belmont Development Co. in March milled 8047 tons of ore, and sent 562 tons to the smelter. The total net value of the ore is announced as \$230,882. The production of gold bullion for the month amounted to 3203 oz., and silver bullion to 311,091 oz. The company's net profit for March is given as \$146,629.

The production of the Tonopah district for the week ended April 13 is thus summarized by the *Tonopah Miner*: The Tonopah M. Co. sent 3150 tons, the Belmont company 1750 tons, the Montana-Tonopah 1053 tons, the Tonopah Extension 1012 tons, the West End 600 tons, and the MacNamara 390 tons, making the total production for the week 7955 tons, the estimated value being \$198,875.

STOREY COUNTY

The customary weekly reports of the superintendents of the Comstock properties for the week ended April 13 show, among other things, that the Ophir, in the course of development, produced about 200 tons of ore, and shipped to the Kinkad mill about 368 tons of second-class ore. In the east cross-cut on the 2500-ft. level of the Union Con. M. Co. property, a 2-ft. quartz vein was cut during the week. The cross-cut was driven 21 ft. in the week. Samples from six ears assayed an average of \$21.12 per ton. A geological study has been made of the Patton cross-cut. In the Con. Virginia the three-compartment raise is now 37 ft. long, and during the week some low-grade ore was saved in making the raise. Work in the mine was stopped four days to allow the Pumping association the use of compressed air in pumping out the 2500-ft. level and the 2200-ft. level winze of the Ophir. The Mexican mill ran 81% of the time, crushing 459 tons of ore. The average head was \$24.88 per ton and the apparent extraction 90%. Some low-grade ore was saved in development. The Crown Point put 1119 tons of ore in the bins of the Yellow Jacket mill during the week. Along with other work, the Pumping association pumped dry the 2500-ft. level of the Ophir, and constructed a dam in the old north drift. The usual activity was seen at other properties. The Ophir company last week reported receiving \$25,000 from a shipment of concentrate to the smelter.

WHITE PINE COUNTY

Work will be resumed in the near future at the Butcher Boy claim of the Coppermines property by the Thompson-Gunn interests, according to recent reports. Arthur Smith is general manager of the property. The American Rare Metals Co. is to start development immediately on its property, which is about seventy-five miles from Ely, and five miles from the Utah line. The claims are said to have rich tungsten ore. Jeremiah Nolan, president of the company, and sons are visiting the property. The journey was by way of Oasis and required a stage ride of 100 miles.

NEW MEXICO

DONA ANA COUNTY

The Turgite M. Co., capitalized at \$250,000, with shares \$100 each, has been formed at Las Cruces. The list of incorporators is headed by E. C. Wade.

GRANT COUNTY

It is rumored that the Eighty-five company will build a reduction plant for its property, near Lordsburg. Last month 148 cars of ore was shipped from Lordsburg.

On Lone Mountain a prospector named Elliott found

high-grade silver ore recently. Near his discovery he also found old implements such as were used by the early Spaniards and by the Indians in mining. J. E. Pierson has put in operation his cyanide plant and is treating the tailing from the site of the old Hearst mill, two miles from Pinos Altos.

The third unit of the Chino Copper Co.'s concentrator was started about two weeks ago. The fourth unit should be ready by May, and the entire plant operating by July 1. The Hearst part of the mine is about ready for production, which will mark the company's first treatment of sulphide ore. The two units of the concentrator which have been in operation have approached 1100 tons per day, as against a rated capacity of 1000 tons. Costs are said to have been well under 8c. per pound.

SIERRA COUNTY

John Calvin is about to secure a set of hand jigs for his mine on Pereha creek. The experimental plant at the U. S. Treasury property, in the Black range district, has proved satisfactory and a larger mill will be ordered.

OREGON

BAKER COUNTY

The Yuba Construction Co. has started work on the dredge ordered by the Powder River Dredging Co. Fred Deland and F. J. Ryan have charge of construction.

C. D. Snyder and son, of Parma, Idaho, with Joseph Watts of Granite, are planning extensive development of their placer property in the North Fork district as soon as the spring floods start. The Granite Con. Placer Co. also will start operation soon.

JACKSON COUNTY

Letters from friends in South America have caused about twenty-five Medford citizens to plan a trip to Bolivia, to investigate gold properties, says a report in the *Medford Sun* of April 16.

UTAH

JUAB COUNTY

The Iron Blossom company on April 25 will disburse its second quarterly dividend of the year, which will be 10c. per share, as against 7c. paid for the first quarter on January 12. While no financial statement has been issued, it is rumored that after \$100,000 disbursement required for the dividend, the company will have \$150,000 in the treasury.

TOOELE COUNTY

The plant of the Ophir Hills company, owned by W. A. Clark, in the Ophir district, is to be doubled, to have a capacity of 300 tons per day.

CANADA

ONTARIO

March ore-shipments from Ontario properties amounted to 1714 tons, as against 2099 tons in February. As a rule, only high-grade ore was shipped, and the low-grade ore properties were not on the list of March shippers.

The shippers in detail were as follows:

	Ounces.	Value.
Nipissing	343,706	\$202,711
Crown Reserve	65,181	37,266
O'Brien	19,870	11,277
Buffalo	7,670	4,500
Cobalt Townsite	3,000	1,750
Trethewey	2,024	1,093
Totals	411,451	\$258,597

(Special Correspondence.) The Domes Mines management report good results from the mill output. So far the extraction will average 97%, and has reached over 99%. The results of the underground work has been encouraging. The West Dome is cross-cutting from the No. 1 shaft at the 100-ft. level, and is driving west and cross-cutting north from the No. 3 shaft at the same depth. The Crown Chartered expects to begin operating the new compressor soon, and to reach the 200-ft. level in its shaft by April 20.

The Scottish Ontario is still closed down pending a visit from one of the board of directors. The stock having been underwritten in Great Britain, the managing director is to inspect the property and, after consultation with the management, to decide on the plant and other equipment to be installed. Excavating is well under way for the 20-stamp addition to the McIntyre mill, and work is being rushed on sinking No. 1 and 4 shafts.

South Poreupine, April 11.

The McIntyre mill, Poreupine district, during March, although running less than three weeks owing to power difficulties and the installation of boilers, produced \$6000 from its ten stamps.

MEXICO

HIDALGO

The mill of the El Oro M. & R. Co., controlled by the Exploration Co., Ltd., in March ran 29 days, treating 21,300 tons of ore and 11,410 tons of tailing. The bullion production amounted to \$172,120. Operating expenses and cost of development amounted to \$118,830, leaving a net profit of \$53,293. Adding the profit on the railroad, \$8820, the total net profit for the month was \$52,110. On permanent improvements \$1150 was spent.

JALISCO

A branch power-line is under construction to the Casados mines in the Hostotipaquillo district from the transformer station at El Favor. The properties, which are owned by the Con. M. Co., of which W. R. Ramsdell is president, are under option to William Bailey of Los Angeles, California. The price named is \$4,500,000.

As the result of arrangements just completed, several carloads of copper ore from the Zapote mine in the Ameca district will be shipped in a few weeks. The properties are under option to E. A. Montgomery, at a price of \$100,000. Shipments are planned also at the Magistral mine of the Magistral-Ameca Copper Company.

Among the Copper Mines

The NEVADA DOUGLAS company is shipping 340 tons of 5½% copper ore per day to the smelter. W. C. Orem, general manager, states that development in the Ludwig and Casting mines is better than the company hoped for.

HENRY R. MERTON & Co., copper brokers, of London, who are credited with having played a large part in the recent moves which rescued the copper situation, estimate the world's production for 1911 at 1,956,550,400 lb., as compared with 1,916,734,000 lb. in 1910, an increase of 2.1 per cent.

SOUTH UTAH MINES & SMELTERS, the former Newhouse property, is slowly working out its problems and is one of the string of producers that at low prices was obliged to operate without much hope of profit, but which can now make a little money. E. P. Earle, of the Nipissing Mines Co., handles the copper of the South Utah.

'STANDARD' COPPER shows an advance of £6 10s. per ton during the past month, says James Lewis & Son's monthly report. From £64 2s. 6d. cash rose to £65 2s. 6d. on March 6, but receded to £64 on the 11th. There has since been a steady advance, with but slight fluctuations, to £70 12s. 6d., up to £71 15s. being paid April 1 for three months' prompt—from which there has been a reaction to £71 10s. Sales total about 51,000 tons. The strong statistical position of this metal is now being generally recognized, a further reduction of 1482 tons in the European stocks having taken place in face of the reduced English deliveries due to the colliers' strike. Large purchases of refined copper have been made by American consumers for delivery over the next three months, resulting in an advance to 16c. per pound for electrolytic and 16½c. for Lake copper, with sales of wire bars up to £73 per ton c.i.f., £73 17s. 6d. being now asked. The New York

Custom House advises an error in the exports to France for the month of February of 3524 tons, which reduces the consumption of France given in our last report by that quantity—to 12,736 tons. German consumption for the months of January and February amounted to 33,974 tons, as against 25,838 tons for the same months last year, an increase of 8136 tons, making the total European increase in consumption for the two months this year over last 13,247 tons, or at the rate of nearly 80,000 tons per year. With an increase in the American consumption of 11,596 tons, or at the rate of 70,000 tons per year, a total increase of production of about 150,000 tons will be required to maintain American and European stocks at the low level attained on January 1 should this increased consumption be maintained throughout the year in the same ratio. American exports from northern ports for March are advised as 26,764 tons. European stocks have decreased 1482 tons and the visible supply 1932 tons during the month. Imports are 1027 tons less and deliveries 1926 tons greater than during the same period last year. The total arrivals in England and France for the month have been 17,078 tons, and the deliveries 17,960 tons. The arrivals in England from Chile during the month have been 1705 and the deliveries 1337 tons, and from other countries 10,623 and 12,325 tons, respectively. The arrivals at Liverpool and at Swansea from the United States have been 2914 tons bars, 1014 tons plates, and 17 tons matte, equal to about 3911 tons, in London 225, and in France 4300 tons fine. The Chile charters for the month are advised as 1600 tons, including 425 tons for the United States.

March Copper Review

By MISHA E. APPELBAUM

The statistics for the month of March show an increase in domestic deliveries of about 11,000,000 lb., a slight decrease in exports, and an increase in production of about 7,000,000 lb., due to the fact that March has 31 days against February's 29, so that, on the whole, the production and the exports are about the same, but the domestic consumption is showing signs of sharp improvement. The visible supply is now the smallest since 1907 and domestic deliveries can with reasonable safety be counted on at about 70,000,000 lb. per month for the next two or three months and it can also be expected, since the coal strike is settled in England, that there will be a revival in industry and that Europe ought to take 60,000,000 to 65,000,000 lb. per month, so that even if the production is increased to 135,000,000 lb. per month, the visible supply will not increase, although, personally, I expect that small decreases will take place.

In view of this, it is difficult to foresee anything else but higher copper prices, although the market is now entering upon an era of prices which, if carried much further, will undoubtedly some day check the consumption. If the market, therefore, can be kept between 16 and 16½c., it will not interfere with the consumption and leave a remunerative profit to the producers. I understand from the majority of the copper people that they are doing all in their power to keep the market from getting beyond them, but with most of the producers sold out and the demand keeping up, they really are powerless to do much, and it is therefore likely that, from time to time, sharp bulges will occur when the market through the consumers' anxiety will be carried higher than the producers themselves would like to see it go. A favorable influence on the copper market which I have not mentioned before is the fact that the entire country seems to be recuperating from the depression from which it has suffered during the last four or five years. The conservative element is bound to dominate both of the political parties, and I do not think it will make any difference to legitimate business interests which party is in power, so that the entire aspect of the business situation is such as to make one feel optimistic, and that, in addition to the sound statistical position of copper, naturally makes the outlook for the next few years one of great promise to the copper trade.

Personal

Professional men are invited to send news of their engagements and travels. Such news is interesting to friends.

K. C. PARRISH is in Colombia.

FRANK DENNIS has gone to Chicago.

D. J. SULLIVAN has returned to Arizona.

WEBB SMITH was in San Francisco Tuesday.

M. P. MORRIS has returned to Salt Lake City.

H. S. DENNY is returning to London from Mexico.

O. R. WHITAKER is at 932 Equitable building, Denver.

R. S. BOTSFORD has gone to Vladivostok from London.

RITTER VON GROT has gone to Chicago by way of Los Angeles.

JOHN H. BUXTON, of Baltimore, was in San Francisco this week.

M. J. MONNETTE was in San Francisco from Los Angeles this week.

H. W. HARDINGE was in San Francisco and Los Angeles last week.

J. M. MITCHELL is now at 71 Jamaica avenue, Flushing, New York.

CHARLES JANIN is at the Hotel Russell, Russell Square, London, W. C.

DAVID MUIR is manager for the Needles Smelting Co., Needles, California.

H. A. LINKE is manager for the Nevada Central Copper Co., Cedar, Nevada.

H. F. LEFEVRE has gone to Guatemala, expecting to return by the middle of May.

H. R. PLATE has an office as consulting engineer at 14 Wall Street, New York City.

C. O. G. LARCOMBE has returned to Kalgoorlie from a trip through Eastern Australia.

OLIVER B. FINN has returned to Colorado Springs from a professional trip to Alabama.

R. S. STOCKTON has returned to Strathmore, Alberta, Canada, from a visit to Denver.

PHILIP ARGALL & SONS are consulting engineers for the Ozark Smelting & Mining Company.

J. E. SPURR and M. B. HUSTON have been at Ely, Nevada, sampling the Taylor and Ward mines.

C. B. LAKENAN is in New York, attending the annual meeting of the Nevada Copper Company.

IRVING H. REYNOLDS, former chief engineer for the Allis-Chalmers Co., has returned to that company.

J. EMERSON GEE is resident manager for the Indiana-Oaxaca Mining Co., at Sola de Vega, Oaxaca, Mexico.

C. T. DURELL has arrived in Denver, on his return from the Philippine Islands by way of Australia and Peru.

L. STEWART and J. I. KANE are on the engineering staff of the Tiro General mine, at Charcas, San Luis Potosi.

WALTER NEAL is general manager for the El Favor and Mololoa mining companies, at Hostitopaquillo, Jalisco, Mexico.

JAMES HEGGIE is superintendent and R. B. GREEN is assistant superintendent of the A. S. & R. Co. smelting plant at Hayden, Arizona.

GEORGE WATKIN EVANS has resigned from the Washington Geological Survey and will practise as consulting geologist at the Leary building, Seattle.

YOUNG MEN who understand work with Empire and Keystone drills and are willing to take employment abroad are asked to register their addresses with the Editor.

MARK L. REQUA will discuss the 'Problems that Confront the Oilmen of Today,' before the Mining Association, the student branch of the American Institute of Mining Engineers, in room 200, University of California, at 8 p.m., Wednesday, April 24. The public is invited.

Decisions Relating to Mining

Specially reported for the MINING AND SCIENTIFIC PRESS.

ASSESSMENT WORK PENDING PROCEEDING FOR PATENT

Where a locator filed application for patent, published notice, and thereafter failed to perform the annual representation work on his claim for several years, it was held that a second party might re-locate his claim as forfeited, at any time before payment of the purchase price therefor, and then obtain an injunction restraining the original locator from continuing patent proceedings. Assessment work must be continued up to the time when payment of the purchase money is made to the Government.

Poore v. Kaufman, (Montana) 119 Pacific, 705. November 24, 1911.

PLACER LOCATION REQUIREMENTS—NUMBER OF CLAIMS THAT MAY BE TAKEN BY ONE LOCATOR—MONUMENTS—DUMMY LOCATORS

There is no limit to the number of placer claims that may be located by one person or association of persons; hence, the location of a second claim cannot be urged as indicating the abandonment of a former location whose boundaries do not conflict with those of the second. Monuments found upon ground at the corners of a placer claim may be adopted by the locator as his own and will meet the requirement that the claim be marked on the ground by substantial monuments. The Government alone can complain of fraudulent locations by 'dummy' locators. Except in adverse proceedings, where the Government is a silent party, such a location is not open to collateral attack by individuals.

Riverside Land & Cement Co. v. Hardwick, (New Mexico) 120 Pacific, 323. December 1911.

OIL LEASES—RIGHTS OF SUB-LESSEES

An oil and gas lease for fifty years gave the lessee the right to develop land described for oil, gas, and mineral, and to sell the same when acquired. The lessee sub-leased to a third person for twenty years the exclusive right to drill wells on a part of the land, work to commence within a specified time. The sub-lessee went on the land and deposited a wagon-load of well-drilling tools thereon, intending to commence work, but was stopped the next day by the original lessor, who claimed that the lessees had forfeited their rights in failing to develop the property themselves and in assigning their lease in part. It was held that in the absence of an express covenant to the contrary the first lessees could sublet all or part of the land described to a third party, to develop for oil or gas, and that the entry of the sub-lessee was sufficient to support his suit against the original lessor for possession, for an injunction preventing the lessor from further interfering with him, and for damages.

Chandler v. Hart, (California) 119 Pacific, 516. December 1911.

MINING CLAIMS—EFFECT OF CANCELLATION OF FINAL RECEIPT AND ENTRY

The Secretary of the Interior cancelled the final receipt and entry for patent of certain placer claims, on the ground that two of the affidavits required were sworn to in the wrong land district. Prior to the cancellation adverse locations were made covering the same claims. Subsequent to the cancellation, the former applicant resumed possession of his claims and started patent proceedings anew. The adverse locator filed a contest and brought suit claiming that when the first entry was cancelled the land in question was thereby restored to the public domain, and thereupon became subject to his locations. But the court held that such was not the case; that the cancellation of the patent proceedings merely operated to restore the applicant to his status as a locator, and that, providing he had performed his assessment work, his first locations were still effective.

McKnight v. El Paso Brick Co., (New York) 120 Pacific, 694. December 23, 1911.

Concentrates

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

SIDE-LATCHES on ore-cars are apt to prove objectionable in underground work, as they are apt to catch on the timbers in narrow workings.

FREE-MILLING ore in California always contains a certain amount of sulphides, usually about 2%. These are concentrated and then either shipped to the smelters, ground in tube-mills and cyanided, or treated by the chlorination process.

WORK on a mining claim used in application for patent must have been performed by the applicant or his grantor. Work existing on claims when located cannot be entered except by fraud, but work done by the locator may be counted toward patent by one who buys from the locator, if it be otherwise applicable.

ORE should not be roasted before concentration, as it is too expensive. Roasting will ordinarily cost from 75c. up per ton, depending on the method employed, while concentrating can ordinarily be done for little more than half that sum. In addition, better results can ordinarily be obtained on raw ore than on roasted material.

PRESSURE of the wind on a building varies nearly as the square of the velocity. Thus a wind with a velocity of 20 miles per hour produces a pressure of 2 lb. per square foot, while a wind velocity of 40 miles per hour has a pressure of 8 lb. per square foot. It is probable that the pressure on large surfaces is greater than on small ones, owing to the disturbing effect of the edges.

LARGEST gas-engine units ever constructed are those installed in the new power-house of the Indiana Steel Co. at Gary, Indiana. They have a rating of 3200 kilowatts (4228 hp.) each. The new engines are of the twin tandem double-acting Allis-Chalmers type, with cylinders 44 by 60 in. The engines will operate on blast-furnace gas, and are to drive alternators delivering 6600-volt, 25-cycle, 3-phase energy to the power network of the Gary mills.

KNOCKING in the cylinder of a straight-line air-compressor is often caused by the reversal of the connecting-rod function in the middle of the stroke. If the thrust of the cross-head is downward at the beginning of the stroke it will be upward at the end, and conversely. To prevent knocking, the bearings and connections should be kept set up as snug as possible, and vertical play between the cross-head and the slides should be especially guarded against.

LARGE vertical drawing-boards may be arranged conveniently in the following manner. Screw a pair of bearings to the top edge of the board; through these pass a rod or piece of small shafting, running the entire length of the board and extending sufficiently beyond at each end to receive a pair of sprocket wheels. Attach chain belts to each end of the movable straight-edge, and pass over the sprocket wheels, and attach to a pair of counter-weights sufficiently heavy to balance the weight of the straight-edge when at the position most used. As both sprockets are firmly keyed to the shaft, any movement at one end of the straight-edge insures an equal amount of motion at the other. Sprocket wheels and chains, of the type used in bicycles, will be satisfactory for the purpose, though chains of lighter weight, such as are used for hanging pictures, if constructed without play, will perhaps be more desirable. A small clip or slide fixed to the projecting ends of the straight-edge at the back, and passing under the edges of the cord, will prevent the straight-edge from lifting away from the face of the board.

CANADA will begin minting \$5 and \$10 gold-pieces at Ottawa next month, and presumably American gold-pieces will begin soon to find their way back across the border.

COAL LANDS in Colorado amounting to 8465 acres have been returned to the United States by the Denver & Rio Grande railway, as a result of suits brought by the Government, alleging fraudulent entry.

BILLS have been introduced in Congress at the instance of the Alaska committee of the American Mining Congress, providing for needed railroad building and leasing of the coal lands. In the meantime Democrats and Republicans jockey for position and the Government charters eight British steamers to transport coal from the Atlantic to the Pacific coast.

REPORT of the Nipissing Mines Company for the year 1911 shows a production of 4,678,074 ounces of silver; somewhat less than the preceding year, but a worthy record none the less. Nipissing is the chief producer of a notable group of silver mines at Cobalt and South Lorrain, the La Rose having produced 3,691,797 ounces in 1911; the Crown Reserve, 3,430,902; Coniagas, 3,273,464; McKinley-Darragh, 2,551,884; Kerr Lake, 2,238,353; and Buffalo, 1,644,245, while three other mines produced over a million ounces each. The total silver production of Ontario in 1911 was 31,507,791 ounces, all derived from the vicinity of Cobalt.

EXTRALATERAL rights are not to be granted with claims hereafter located, if the bill introduced in the Senate at Washington by Mr. Reed Smoot becomes a law. All claims are also to be recorded in the local land office within a year of their location. Both of these changes are important and should be made, but the particular bill is not well drawn and falls far short of the thorough general revision of the mining law that is needed. In the series of articles on the birth of the American mining law, written by Mr. H. W. MacFarren and concluded in this number, it will be noted that while specific changes proposed are approved, strong ground is taken against a general revision. We do not, in this, agree with our contributor, but we must admit the probability that the needed changes will be made piece-meal.

MIAMI has made a good record during its first year. Production was begun on March 15, 1911, on a small scale, which was gradually increased during the year. The output was approximately fifteen million pounds of copper, or a little over one-third of normal production, at an operating cost of 9.325 cents per pound. Mr. J. Parke Channing, the consulting engineer, draws attention to the fact that the cost of mining at the top of the orebody, where the covering of the orebody with a mat of timber is in progress, is necessarily greater than for subsequent operation, while the ore from this part of the orebody yields a less percentage of extraction than it is hoped to attain later. Under Mr. Channing's direction the Miami is evidently operated to

produce sound technical and financial results, rather than to secure spectacular effect.

RAND MINES made another record output in March, the production for that month reaching 830,723 ounces. During 1911 the Crown Mines milled 1,613,400 tons, at a working profit of £1,272,944, or 15 shillings 9 pence per ton. This tonnage was exceeded by both the East Rand Proprietary and the Randfontein Central, which milled 2,194,552 tons at a profit of £913,862, and 2,157,331 tons at a profit of £862,000, respectively. The record for productivity belongs to the Robinson, which yielded £910,949 from 591,700 tons, or 30 shillings 11 pence per ton. This is a notable record, and none the less so that while output has been expanding profits have been contracting, while operating costs show a deplorable tendency to increase in many instances. Operations suffered, in several instances, from what in America would be called 'shake-ups.' In his speech at the annual meeting of the Transvaal Chamber of Mines, Mr. H. O'K. Webber sounded a cheerful note of optimism as to the outlook for future mining, and it is to be hoped that his predictions may be justified by the event.

METHODS of presentation and keeping of accounts by mining companies are of almost infinite variety, not to say complexity. This is in part due to the fact that the necessary accounts of a small company are naturally much fewer and simpler than those of a large corporation where, for convenience, separate departments are often organized in the form of subsidiary companies. Waste of experience is the rule, however, and it not uncommonly happens that the system employed represents the development of ideas as worked out by the chief accountant. But an unsatisfactory system gives nearly as much trouble in its readjustment as in its continued operation, and a broad familiarity with the successes and failures of others would often prevent the inception of a system of accounting which affords present advantage at the expense of great future inconvenience. We welcome, therefore, the organization of the International Society of Mining Accountants, which announces as its object "to promote the science of accounting and allied subjects connected with the production of useful minerals and metals on the American continents." Much good may result from its activities, and we wish it a full measure of success.

BUTTE faces the possibility of labor troubles, as the agreement which has been operative for the past five years expired April 1, and agitation for an increase of wages is being mooted. The former agreement produced great general satisfaction, and it is to be hoped that a similar one may again be made. It is not unnatural that workmen should consider that the increased operating profits of the companies resulting from the increased price of copper ought to give rise to larger returns to the miner in the form of wages, but if this principle is asserted the miner should be equally ready to accept a cut in wages when the copper market declines. This plan obtains in the anthracite fields, but has its defects and limitations. A theorist might propose to reckon each week's wages upon the basis of the average selling price of copper during the week, but aside from the practical difficulties of such an arrangement it has the disadvantage of transferring the burden of fluctuation from the corporation of large resources, which is prepared to bear it, to the individual of small resources, who is not prepared to carry it, thus reversing the line of social economic development. Periodic readjustment of wage schedules, whenever changed conditions may require it, seems the best method of securing satisfactory relations between employers and those employed.

THE value of a man is something hard to translate into figures, and the time has passed when men can be bought and sold. Judged only as a working machine, however, it is possible by use of mortality tables to determine the probable future earning capacity of any individual. This is the figure that actuaries use as a basis for annuity insurance, and it is interesting to see that a miner in good health at 30 years of age and earning \$3 per day is worth over \$17,600 as a working machine. The value decreases with age and increases with earning capacity. At 50 years the value is \$4359 for each dollar of daily wage—not \$359, as stated through a typographical error in the letter on 'The Mine-Owners' Liability for Accidents,' by Mr. A. J. Pillsbury in our issue last week. Mr. Pillsbury's letters now being published, by the way, will repay the thoughtful reading of everyone interested in the betterment of labor conditions, as well as those concerned with the economies of mining.

ELECTRIFICATION of the lines of the Southern Pacific railway which circle San Francisco bay is of interest to the copper miner as creating a considerable local demand for that metal. But trade follows regular channels, so that this supply will be drawn from Eastern points. Practically all of the copper of the United States is produced west of Chicago, yet six of the eight refineries, representing 95 per cent of the total output, are situated on the Atlantic seaboard. This is the result of present economic conditions. Nearly all the manufacturers, both of finished and unfinished products, and a large majority of consumers are in the Eastern states, while a minor point is that the associated gold and silver must usually be sent East, and can be shipped more cheaply and safely by freight while locked up in blister than by express in the form of doré bullion. Reasonable continuity of operation is essential to the success of refining and manufacturing industries, and this is conditioned upon continuity of demand. Until the Pacific seaboard is much more densely populated than at present, so as to afford continuity of demand through force of numbers, local metal refining and manufacturing will continue to grow but slowly.

RIVERS exemplify the law of compensation. By their work they build up alluvial plains of great fertility, and then proceed to devastate them in times of flood. Conditions have been serious in the Mississippi Valley recently, but public attention has been diverted from them by absorbing interest in the *Titanic* disaster. The natural action of a large river traversing a flood plain is to build up levees which serve to confine it to its course under ordinary circumstances, especially when these are reinforced by human effort. But when the river rises unusually high in times of flood great destruction will result unless the levees can steadily be maintained. In 1890 the Mississippi broke through its levees near New Orleans and, flowing with a current of 15 miles per hour through Lakes Ponchartrain and Borge, spreading devastation in its course, entered Mobile bay in such volume and velocity as to destroy the fishing and oyster industries. A worse offender is the Yellow river (Huang-ho) of China, which traverses for hundreds of miles an extensive plain that is almost without relief. Within historic times it has more than once completely changed its course, and has wrought so great destruction as to well deserve the name of 'China's Sorrow.' Considerable sums are required to control the activities of these vagrant rivers, and in a special message to Congress the President has asked for an appropriation of \$787,000 to supplement that of \$350,000, made earlier in the year, for the up-keep and protection of the levees along the Mississippi.

Progress of the Zinc Industry

Zinc metallurgy has gained in importance of recent years, as a comparison of the United States output of 1911 with that of 1896 shows. Production of spelter in 1896 was 77,637 tons and the average price per pound at New York was 3.94 cents. In 1911 the output was 268,526 tons and the average price per pound 5.76 cents. Compared with the advance in production and price the improvements in the metallurgy might seem disproportionate, for the century-old Belgian process still largely holds its own in spite of much study, for zinc is an unruly metal and offers stubborn resistance to the metallurgist. Most of the zinc ores treated today throughout the world are complex, containing important quantities of silver, lead, and copper. In the Belgian plants the recovery of lead and silver is seldom over 70 per cent, and is often much less, while a most important factor which militates against the further extension of the process in old regions and its introduction in new is the question of labor. Not only are the demands of labor increasing, but also it becomes increasingly difficult to replace men of the older generation with skilled furnacemen. Even in Belgium, where perhaps the greatest skill in operating retort furnaces is to be found, this pressure begins to be felt, and tends to become more aggravated each year. Improvements which will do away with the requirement of skilled labor and yield an increased saving of associated metals are at a corresponding premium. Two electric zinc plants are now in operation in Scandinavia and though the technical results, judged from a Belgian standpoint, are low, the operating profit is considerable, thus meeting the requirements of the basal definition of metallurgy as the art of making dollars out of ores. The art of electric zinc smelting is in its infancy, improvements must and will be made, and there seems good reason to believe that electric furnaces embodying the essential features of the Belgian process and duplicating or improving on its conditions as to chemical reactions, temperature, and physical conditions are likely in the near future to receive increasing application.

In the meanwhile attention has been generally focused upon better dressing of the ores preliminary to furnace treatment. In the United States this took shape first in development of magnetic, and later of electrostatic, concentration. Fire concentration has only been used in special cases, and, while the Wetherill and Bartlett processes have permitted direct treatment of low-grade and mixed ores in special furnaces, they have only been adapted to the making of pigment. Spelter is still made here, as abroad, in retorts. In Australia, as in the United States, there are large bodies of low-grade mixed sulphide ores containing zinc that formerly were valueless. With the successful development of the flotation processes these came to yield valuable concentrates. At first they were shipped to Europe for treatment but eventually a zinc smelter was built at Port Pirie. It is interesting to note that this plant was constructed along standard lines and that the chief troubles that have been met in getting it to running smoothly arose from the lack of a sufficient supply of specially trained laborers. That success has been achieved proves again that in building up a new zinc smelting centre there is nothing inherently impossible, but merely an unusual number of minor and annoying difficulties. With the high labor costs obtaining in Australia, an electric furnace would seem to have advantages, but when construction began there, the work in Sweden had not gone so far as now, and it is said that even in Sweden a quarter of a million dollars was spent before the present practice was developed.

In California conditions are similar to those in Australia. There are considerable bodies of complex zinc ores, and at

least a small local market for spelter with easy access to the sea. Flotation can be applied to the ores and a satisfactory concentrate can be made. To ship this to existing furnaces absorbs the bulk of the possible profit. To establish an ordinary retort furnace would be to face labor troubles under all the usual disadvantages, with a few peculiar to California. Electric smelting is being tried with good prospects of success, but leaching processes, to be followed by electrolytic precipitation, are also being studied, and at the moment it seems probable that development in California will be along this line.

In Canada a determined attempt is being made to find a process that may be applied with profit in zinc smelting, and a Government commission is now studying the subject. An electric furnace was built and a series of trial runs made, but the large scale work was stopped before final results were obtained. For the present the commission seems to be content with watching work elsewhere, though doubtless in time the experiments begun in British Columbia will be resumed.

The latest country to attempt local treatment of its zinc ores is Japan. In that country there are, as in the United States, Canada, and Australia, considerable bodies of mixed sulphide ores of which the zinc content has heretofore been largely wasted. In part these ores have been dressed and shipped to Europe. Export shipments of zinc in ore in 1909 amounted to 152 tons, and in 1910 and 1911 the figures were 140 and 143 tons respectively. This zinc was valued at \$320,000 to \$400,000, but in the same years spelter was imported into the Empire as follows:

	Short tons.	Value.
1909	3,206	\$995,663
1910	6,786	1,407,151
1911	7,395	1,587,339

It is now announced that the Mitsui Mining Company will build a smelting plant at Omuta on the island of Kyushu. The principal source of ore will be the Kamioka mine, which belongs to the same company, and which is situated near Toyama. The ore at this mine contains 10 to 25 per cent of zinc, 2 to 14 of lead, about 15 ounces of silver, and a small amount of gold. The present annual output is about 10,000 tons. Wet concentration followed by flotation treatment of zinc middling from Wilfley tables is employed. The flotation process was developed locally, and a technical description has not been published. It is interesting to learn that the new smelter is to be of standard type, though owing to the absence of clay of the best quality a special process is to be used in making the retorts. This follows American experience, where great improvement has resulted from introduction of the hydraulic press into retort making. One peculiarity in the new Japanese plant is that the retorts are to be heated with waste gas from the by-product coke ovens now being built at the Miike coal mine. In the United States natural gas and producer gas have both been used, but we believe this is the first attempt to utilize coke-oven gas in this manner. That there will be many difficulties before the new works run smoothly is to be expected, but with cheap fuel, abundant labor, a satisfactory supply of ore, and a high price for metal, the project is certain of final success. Whether Japan will become an exporter of spelter is a problem for the future. Too little is known yet of the available supplies of zinc ore and Japanese workmen have still to be trained in the difficult art of zinc smelting. It is believed that the ore supply is sufficient, and it is known that on the Siberian coast, as well as in China, there are deposits to supplement those of Japan, but the training of a large group of workmen in an art new to them is a long task, and for some time even the capable engineers of the Mitsui company will have their hands full supplying the local market.

Possibilities of British Papua

By A. W. ALLEN

The results of exploration into the interior of British Papua have shown how little was known of the country at the time of my stay there, for some 15 months, ten years ago. The intrepid daring of the bands of explorers who have of recent years contributed so much to our knowledge, is an object lesson; and their experiences and records, apart from claiming our interest, are of considerable economic value in estimating the potentialities of that part of the world.

The search for gold in New Guinea was the object of a party of Australian prospectors, as long ago as 1878. Their quest was, however, unsuccessful; and the death roll disheartening. In 1884 a British Protectorate was proclaimed, the first Commissioner succumbing from malaria. The Protectorate was subsidized by three of the Australian states to the total amount of \$75,000 per annum; and, in 1888, a year marked by the discovery of the first goldfield, the portion annexed was proclaimed a part of the British Empire, and became a Crown Colony. In 1902 the administration and control was placed in the hands of the Commonwealth of Australia, the title being afterward altered from British New Guinea to Papua, the original native name of the island.

The first Lieutenant-Governor appointed was Sir William McGregor, at one time principal medical officer at the Fiji Islands, where his capabilities, beyond his medical duties, had been duly recognized by the Colonial Office. His appointment to British New Guinea was a particularly wise one, his natural administrative ability being coupled with a knowledge of hygiene and medicine which was of inestimable value in the pioneer work connected with the development of a tropical country. To the soundness of the first administration Papua owes much of its present stability, and the white population their personal security. The law as to the confiscation, and prohibition of manufacture, of any kind of weapon among the natives, did much toward the elimination of inter-tribal feuds; and the strict measures taken in respect to the sale or gift of alcohol to the natives were of considerable benefit to the community. The two principal towns, Port Moresby and Samarai, were laid out on healthful sites, the latter being situated on an island a short distance from the mainland. Swamps were drained, cocoanuts were planted, and strict by-laws dealing with the question of the exposure of even small quantities of fresh water on private property resulted in a marked diminution of malaria and the local extermination of the mosquito. The system of recruiting the native police from the ranks of the discharged prisoners from the jails was a bold but successful move, a neat uniform and an antiquated carbine giving them a sense of importance and authority incompatible with a lapse to criminality; and, at the same time, placing the demonstration of the majesty of the law in the hands of a body of men who were feared by the natives on account of their knowledge of the country and their acquaintance with suspicious characters.

To the east and northeast of the mainland the Possession includes several hundred islands, the healthfulness of the climate varying indirectly with size. A number are of coral; others are of volcanic origin, with or without associated coral. The coral islands are, necessarily, low-lying, and the temperature is remarkably equable, necessitating an absolute minimum of clothing, day or night, throughout the year. A cruise among these islands is an experience not soon forgotten. On all sides are seen brilliant patches of green foliage, in a sea of a clearness and color never found outside the blue Pacific; the general effect being often accentuated by a beach-line of bright yellow coral sand. The rate of growth is phenomenal, and the tidal formation of a diminutive island is followed, almost immediately, by signs of vegetative activity; and a few months will see

the starting, by a coconut or two and a few rubber seeds, of what, in a few years, will be a dense tropical jungle.

The reefs and reef-flats form aquaria of intense interest to the marine zoölogist. On the reefs may be seen the cheaper varieties of sponge; and tidal exposure to the blazing sun seems to cause no retardation of growth or development. In the shallow waters may be found a number of forms of diminutive mother-of-pearl oysters, with vivid nacre colorings. Immense anemones provide homes, in the protection of their tentacles, for shoals of small fish whose distinct and brilliant markings are in strange contrast to the coloring of their protectors. In return for lodging they doubtless act as lures for the benefit of their hosts. In the deeper water of the lagoon, sponge of excellent quality, *beche de mer*, and pearl shell are recovered by naked divers; and the bed of the lagoon is clearly visible, on a calm day, to a considerable depth. Green, or alderman, turtle are plentiful in season and form a meat supply for the remainder of the year, the flesh being salted and 'jerked' in South American fashion. Tortoise-shell is exported, but because of the great length of time taken by the turtle to reach maturity, the amount of it is not likely to increase. Nature endeavors to make compensations, the number of eggs from a single 'sitting' often exceeding one hundred. These are left to hatch themselves in the sand, but the advent of the young turtles is awaited, with hungry anticipation, by a score of predatory fish, and few are allowed to survive their first swim.

The flora of the islands is not without interest. The rainfall in Papua would be viewed as phenomenal in other climes; and the frequent and alternating applications of heavy rain and blazing sun on decaying vegetation has produced a soil unexcelled in fertility. Tropical flowers, in immense variety, are found; and the air is laden with their heavy perfume during the short space between day-break and sunrise. Few of these survive the heat of the sun, the majority withering almost as soon as open. Interesting examples can be found illustrating transition stages between wind and insect fertilization; and the insects and bees often show an absence of the trained (or natural) sense of selection in the source of their food supply. The result is that cross-fertilization between different varieties is common, producing abnormalities in what are generally distinguished as fruit and vegetable. Pawpaw, banana, and plantain are grown between coconut trees; and these, with yam, taro, and sweet potato form staple articles of diet. The sweet potatoes produced are very small, and a native once explained to me that, in the soft loamy soil of the coral islands, the tuber had no stones to grow against and expand! Timber is available in quantity and most of it is unusually hard. I observed more than one instance of a mode of protection against 'leaf-cutting' ants, noticeable in South America. A fighting variety of ants is given housing in hollows in the tree trunk, and is supplied with food obtainable from nectaries in the base of each leaf. The constant patrolling of the trunk, branches, and stems serves as a protection for the leaves against the destructive variety of ants, and is an interesting example of the interdependence of plant and animal life.

The coral islands are generally protected by outlying reefs, so that so far as bad weather is concerned, they are habitable. The natives, however, have different views on the matter, and numbers of families leave for the mainland, or the larger islands, before December. That month sees the commencement of a period of calm weather until the tail end of the Indian monsoon makes itself felt, in a terrific tempest, about the middle of February. The usual trade winds then set in for nine months, and the natives return in their canoes to their island homes and congratulate their less timorous countrymen on the fact that the

great upheaval has again been postponed.

In British Papua there is no area, of any extent, where gold has been looked for and not found. In the larger islands, Normanby, Sudest, St. Aignan, Rossal, and Marua, considerable quantities have been obtained from alluvial deposits. At Marua (Woodlark Islands) several veins are being worked; and, from an interesting article by H. Mahon in the *Australian Mining Standard*, it is seen that there are several mills at work there, and at least one cyanide plant, the latter handling the tailing from one-ounce gold ore at the rate of 250 tons per week. A number of properties are being opened in the vicinity, and there is little doubt that later on attention will be re-directed to the other islands, whose prospects may be gauged from the amount of gold which has been recovered from the beds of all the watercourses. Little or no prospecting has been done, the miners preferring a profitable alluvial claim elsewhere to

The total exports from the colony during 1910 were valued at about half a million dollars. Of this amount, the gold production accounted for \$300,000, nearly half of which came from the Woodlark Islands. The white population of the colony has increased steadily since annexation, but the total number is still under 1000 persons. The development of the interior will, doubtless, give opportunity for the development of mining and other enterprise, and the profitable investment of capital.

Labor is plentiful and the Papuans are willing to work if handled cheerfully. One weakness was very apparent at first—homesickness. To counteract the effects of this, the natives are indentured under Government supervision, generally for a year, and sign on and off before a magistrate. This arrangement is an excellent one, and protects both employer and employee. The wages paid amount to about \$2.50 per month, and rice. The natives are kept in

the search for vein gold, and possible disappointment. In Papua the prospector, with the help of a few 'boys', expects a much higher return than would satisfy him elsewhere.

The unhealthful conditions prevailing on the mainland are no encouragement to systematic prospecting for gold. As the country is developed the general conditions will doubtless improve in every way. Large amounts of gold have been obtained from alluvial deposits in a number of localities; and fresh deposits are being discovered as the yield from the older ones decreases. There is little doubt that dredges could be worked in the rivers with considerable profit.

J. P. Thomson makes the following statement in his interesting book* on the country: "It is a somewhat remarkable fact that the geological features of British Papua are, in a considerable degree, identical in character with those of Australia, some of the specimens being coincident with those of the Silurian series from goldfields in New South Wales; while some of the fossiliferous rocks were obtained from beds of clay similar to those at Geelong and Cape Otway, in Victoria. From the foregoing remarks, it may not altogether be unreasonable to assume that mineral areas of great value may yet await discovery . . ."

*British New Guinea, by J. P. Thomson, p. 191.

thorough check by wise legislation and official action.

Any description of the country would be incomplete without a brief reference, at least, to local habits and customs. These, together with the language used, seem to vary with every tribe; and, doubtless, much remains to be discovered. Primitive simplicity prevails in matters of dress; a piece of pandanus leaf for the men and a shredded coconut-leaf petticoat for the women. 'Wives' are bought, sold, or exchanged, but any form of marriage is unknown. Dissolution of the equivalent contract, if any, is common as soon as a change seems desirable. Foodstuffs are obtained from neatly kept gardens, and the love of barter is a significant trait in their characters. Smoked clams are exchanged for sago; tobacco changes hands for betel-nut; and cooking utensils for a supply of sugar cane.

Disposal of the dead is made in curious fashion. In some places the corpses are placed, naked, on a shaded platform, some height above the ground, and allowed to decompose. In other cases burial, in a sitting posture, is the custom, the corpse being made to face the east. The possibility of meeting the ghost of a dead person is a constant source of terror for three nights after death. After that time the spirit is supposed to cease to exist. There are no evidences of a native religion, or of any form of worship.

Tensile Strength of Electrolytic Copper on a Rotating Cathode

By C. W. BENNETT

*As early as 1865¹ it was noticed that during electrolysis, if the cathode were rotated, a higher current density could be used. Among those actually making use of this was Wilde, who patented a process in 1875, using for the cathode a vertical iron cylinder which was rotated. The current density used in this process was never more than 20 amperes per square foot (2.2 A. per sq. dm.).

The next important commercial application of this principle was the Elmore process. In this, the cathode was a mandrel, rotating vertically, over which agate burnishers rotated, keeping the deposited copper tubes smooth, and of constant thickness throughout. This process is used commercially in Europe at present in the manufacture of seamless copper tubes. The current density used is not more than 30 amperes per square foot (3.3 A. per sq. dm.). The copper thus obtained has a tensile strength of from 36,000 to 50,000 lb. per square inch (25 to 35 kg. per sq. mm.), depending, it is stated, on the speed of rotation.² However, a part of this increase in tensile strength over that of copper precipitated on a stationary cathode is most likely due to the increase in the rate of burnishing, for we have here a true analogue to the process of rolling. Due to the increased rate of rotation, the tube passes under the agate burnisher faster, thus giving more and more an approximation to the cold-rolled copper, with its correspondingly higher tensile strength. The Dumoulin process substituted a burnisher of sheepskin for the agate of the Elmore process. It was claimed that the animal fat insulated the projections, thus tending to give a more even surface. The current density was run up to 40 amperes per square foot (4.4 A. per sq. dm.). No mention is made of the strength of the deposit. This was tried commercially in England, but failed completely.

Emerson, in 1899, patented a process³ for making a copper wire by plating copper on a rotating mandrel, wound around with a spiral of insulating material. The strip between the insulating material was then pulled off and drawn down. In 1899 he likewise patented a process⁴ for making copper bars. A copper strip was wound spirally around a cathode which was rotated. The strip was thickened to a bar by depositing the copper on it while rotating. A large [sic] cathode was rotated slowly.

S. O. Cowper-Cowles patented⁵ practically the same process, using a smaller cathode and rotating it more rapidly. The U. S. patent called for a process using a cathode moving "at such a rate of speed that will cause the hydrogen bubbles to be thrown off from the metal deposited on the cathode, and cause such friction between the metal deposited on the cathode and the electrolyte as to yield tough and smooth deposits."⁶

Using a cathode 12 in. (30 cm.) in diameter rotating 1000 r.p.m., and an electrolyte of 12.5% copper sulphate and 13% sulphuric acid, at about 70°C., with a current density of 200 (preferably 170) amperes per square foot (22 to 18 A. per sq. dm.), copper foil was obtained which was even stronger than the best cold-worked copper. The results would have been more conclusive if a thicker deposit had been precipitated and tested.

Five reasons are given for rotating the cathode:

1. The electrolyte is stirred and impoverishment is prevented.
2. The copper is burnished by the friction with the electrolyte.
3. Foreign matter is eliminated, thus preventing 'tree formation.'
4. Air bubbles are brushed away, thus preventing 'nodule formation.'
5. Thickness of deposit is uniform.

There is little doubt that all of these factors enter into and tend to increase the tensile strength, and to enhance the character of the deposit. However, it seems highly improbable that the factors given above are the only ones entering into the equation. For this reason it was deemed expedient to make some experiments, to see if other factors could be found, and to find their true relation to the tensile strength of the deposit. Then the principle was to be applied to the brasses and bronzes with the hope that alloys of high tensile strength would be obtained.

With the copper the various factors were studied by holding others constant and varying one for a series of runs. In this way the effect of speed of rotation, current density, concentration of electrolyte, and temperature were determined. The apparatus consisted of an electrode holder designed to rotate continuously at any speed up to 6000 r.p.m., and carry 300 amperes.

The test pieces were 0.04 to 0.06 in. (1 to 1.5 mm.) thick. The actual deposit before turning down was much thicker. The measurements of the cross section were taken with micrometer calipers, reading directly to 0.001 in. (0.025 mm.). These pieces were then broken in an Olsen testing machine. Five or more tests were made, and their average taken as the true tensile strength.

During the runs it was found necessary to burnish the deposit once or twice. A mechanical burnisher was not desirable, for it would be open to the objection that the copper was being 'rolled' as in the Elmore process. Therefore it was deemed best to stop the run once or twice, depending on the relative rate of stirring and on the current density, and burnish with emery paper. This was done by holding the paper against the rotating tube. The surface was then washed, treated with a strong solution of potassium cyanide to remove grease, and then with 1:1 nitric acid solution to slightly roughen the surface and insure the adherence of the next layer of copper deposited.

In general, if a solution be stirred during crystallization, the crystals resulting are smaller than those from the same solution without stirring, because more nuclei are formed. In depositing a metal, then, if it be precipitated directly in the crystalline state, smaller crystals should be produced if the solution be stirred vigorously. However, the precipitation of the metal in the crystalline state directly is not at all probable. It is likely that the metal comes down in a condition analogous to a 'melt,' and then crystallizes from this. By rotating the cathode the uncrystallized material is agitated and smaller crystals result. The force of the rotation tends to move the material, forcing it to develop new crystal centres, and in this way prevents the growth of large crystals. Hence in precipitating copper, smaller crystals were expected from the run where the rotation was rapid.

It is also known that the tensile strength of steel, copper, etc., is increased by rolling. Rolling, it is generally admitted, does nothing more than break down crystal aggregates, giving a more finely crystalline mass. Hence, with the precipitated copper an increase of tensile strength was expected with a decrease of crystal size, as the rotation was increased. When this was tried the results showed that the theory was correct.

A solution containing 20% CuSO₄·5H₂O and 12% H₂SO₄ was used. The temperature at starting was 35°C. This was desirable, for trial showed that this was the temperature maintained throughout a run at the current density used, 500 amperes per square foot (55 A. per sq. dm.). The deposits were treated alike, and every precaution was used to keep all conditions, save speed of rotation, constant. The experiments showed that:

⁵English Patent No. 26,724, 1898. U. S. Patent, No. 644,029, February 20, 1900.

⁶'Mineral Industry,' 9, 229 (1900).

1. Copper has been deposited electrolytically at a current density of 4000 amperes per square foot, or about 430 amperes per square decimetre.
2. In the electrolytic precipitation of a metal the crystal size decreases as the cathode is rotated more rapidly, other things being equal.
3. The crystal size decreases as the current density increases, and increases as the temperature rises.
4. The concentration of the electrolyte can be varied quite a little without changing the character of the deposit.
5. If the precipitation is carried on at a high temperature an effect similar to annealing is accomplished during the electrolysis.
6. The tensile strength of metals varies inversely as the crystal size, and hence any factor tending to decrease the crystal size tends to increase the tensile strength.
7. The effect of rapidly rotating the cathode and of increasing the current density is to increase the tensile strength, the crystal size being decreased.
8. A good deposit of copper could apparently be obtained at an infinite current density if the stirring were efficient enough to prevent impoverishment.
9. The current efficiency at a high current density with rapid rate of rotation, is high, it being 99.6 per cent.
10. Hard-drawn copper can be deposited on a rotating cathode at almost any current density, if the temperature be kept down; and likewise annealed copper, if the temperature be kept at about 75°C.
11. Electrolytic copper has been obtained having a tensile strength of 68,000 lb. per square inch (47.6 kg. per sq. mm.).
12. A deposit as good as the best can be obtained with a current density of 2400 amperes or more per square foot (264 A. per sq. dm.) with the rate of stirring used.
13. With the alloys, the trouble is most likely a question of colloidal material.
14. Acid solutions, with readily soluble salts and no possibility for the formation of colloids, should be sought for as electrolytes in alloy precipitation.

Russian Platinum Market

ST. PETERSBURG CORRESPONDENCE

The position of the platinum market is a weakening one. The demand is very limited; in fact, it is confined to 'asking prices.' It is said that the stagnation and weakening in price for platinum on the Ekaterinburg market is connected with the sales of larger parcels of platinum by the platinum industrial company under official prices. Offers of platinum on the part of the *staratelli* (local semi-independent workmen) remain as before. Larger supplies are expected to be offered shortly, because some of the *staratelli* who had not worked in the winter time are getting to work again now. Speculators positively refuse to pay high prices. They have considerable stocks which, however, are in strong hands; consequently are not likely to weaken the market. The price for 83% metal is now 9 rubles 90 kopeks per pood. A considerable increase in the production is expected in the course of the present year at the mines of the Platinum Industrial Co. in the Verehotur district, which has decided to extend and develop as far as possible the exploitation of its platinum-bearing areas.

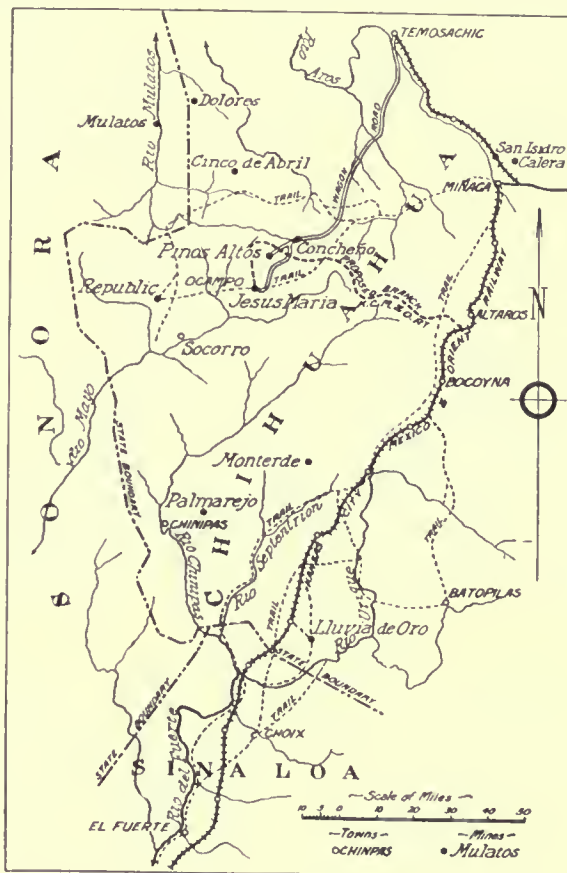

PRODUCER-GAS PLANTS have been utilized to drive centrifugal pumps at Greenbushes, in Western Australia, and the experiment has been so successful that it is probable that this method will be feasible in the Pilbarra district, where the greatest drawback to development is the shortage of fuel supply.

LEAD DEPOSITS on Dolgoi island, which is south of Nova Zembla, have been investigated by Russian engineers, who find that six veins of lead ore occur, estimated to contain altogether 800,000 tons of ore. The climate is said to be favorable for working.

Mines in Northern Sinaloa

By AN OCCASIONAL CONTRIBUTOR

The town of Fuerte, in northern Sinaloa, was first settled in 1556 by the Spaniards. The ruins of the old stone fort, on the river bank, north of the church, could still be seen a few years since. Choix is 40 miles from Fuerte, only nine hours ride away. The lost Gloria Pan mine, according to Spanish records, is about 15 miles east from the Lluvia de Oro mine, on the south of the trail to Urique. The ruins of the old *hacienda* on the creek below can still be seen, and pieces of ores, similar to the Batopilas ores, can be found there. The old trail can also be seen where it starts up the mountain. Many parties have spent much time and money trying to find this mine, and even Porfirio Diaz is said to have had a party there for a month. The Guadalupe Viejo, from all accounts, is a comparatively

low-grade silver mine; the Gloria Pan was high-grade.

There is no trail from Urique to the Fuerte river, locally called the San Miguel, at San Ignacio; it is near Tuvaris, 15 to 20 miles below. The Oro Fino never was a mine or had any value, being simply a stock-jobbing scheme. At the Calabacillas mine there are only two known ore-shoots, the El Poro, which is not extensive and was worked only about 150 ft. deep, and the San Geronimo, discovered in 1900. Here the ore-shoot is 300 ft. long and developed 500 ft. on the dip; the vein is on the contact of rhyolite and andesite, entirely free, even on the lowest level. This shoot has averaged a yield of \$16 gold per ton for the whole production over an average width of about 16 ft. The production has been \$3,000,000. There is an old tailing pile of 10,000 tons of an average value of \$4, made by the Mexican owners, but since A. H. P. Wynne took it over, the tailing probably averages 60 to 70¢. They grind coarse, amalgamate on plates, and leach in cyanide vats. The production of the San Pedro and San Anastacio mines (one) according to Manuel Perez, has been \$2,500,000; silver was then \$1.29 per ounce. It was worked to a depth of only 350 ft. and not far on the strike. The La Dura mines, unless quite recently, have not been worked for a year or two. The management has a lot of machinery at Fuerte, but lacks the money to transport it to the mine.

Birth of the American Mining Act—III

By H. W. MacFARREN

(Concluded from page 564.)

THE APEX RIGHT

It has been said that the apex right was inserted in our mining statutes through a misconception of the nature of ore deposits. This is not entirely correct. The apex right was coined through necessity at a time when the lode was considered the principal thing, when the miner wanted only the lode, and laid claim to merely sufficient ground about it to work it, whether he had found the lode upon its outcrop or through running an adit to cut blind lodes. As economic conditions changed through the working out of rich lodes that could be worked at small cost and thereby requiring only a short length along the lode, large investments of capital and extensive underground explorations became necessary. This required a change from the idea that the lode was the main thing to the consolidation of large surface areas under the strong grasp of fee titles to justify the big expenditures necessary. With this change, and the discovery and working of deposits of such geologic structure as the old-time miner never thought of, the usefulness of the apex right has waned, but no change in the law has been made accordingly. At the time of the passage of this act the apex right was a part of the mining regulations of every district. It was one of the 'miner's bantlings.' Firm in the belief that the lode was the principal thing, the miner believed the apex right to be the corner-stone of successful lode mining. In all the mining communities there was perhaps not one man who was not in favor of it. In 1866, a bill without the apex feature would have been looked upon as a monstrosity. The temporary disturbance from the passage of an anti-apex clause would have been a calamity to the quartz miners. Yet there are those who criticize the framers of the act of 1866, as men of little wisdom and ability because of the insertion of the apex right.

LOCAL COURTS RECOGNIZED

One of the most original features of the act is that adverse claims or assertion of ownership by virtue of separate and distinct locations, are, at time of asking for patent, to be fought out in the recognized courts. This is a departure from all preceding and later public-land procedure. All adverse or contesting claims to public land other than mineral are fought out in the 'land office court'. Each contestant, with or without counsel, appears before the register and the receiver of the local land office and a hearing or trial proceeds along informal lines. The register and receiver render a verdict from which there are appeals to the Commissioner of the General Land Office and the Secretary of the Interior. After final decision, the winning contestant may proceed with his land entry. This is an easy, inexpensive, and well adapted form of litigation upon public-land questions which registers and receivers are reasonably well able to handle. It it could be indulged in in the case of mining claims, every land office in the mining localities would be deluged with true and 'hold-up' adverse claims against nearly every patent applied for upon a mining claim, resulting in a tremendous amount of litigation involving difficult points of law. All this is avoided by requiring the miner to fight his adverse claims out in the courts, and then come into the land office with his decision as to his possessory right to the claim. But this was so arranged for an entirely different reason. Mr. Stewart said: "It [the bill] also provides, in case of dispute as to the right of possession, for the determination of that question in the local courts where the miner's laws are understood and fairly administered." Mr. Conness said: "We do not propose to occupy the register of the land office by determining that question [adverse ownership]. Why? Simply because it would be changing the entire

system that the people themselves have established. They are to be remanded back to settle that question of possession according to the system established by the people themselves; and when that is settled, then the party in whose favor it is settled makes his reappearance in the land office and proceeds to deal with the United States in every step necessary to obtaining title." Mr. Ashley said in the House: "It is objected to the bill that we are to settle that question in our local courts. I tell you all our rights in those mining regions depend upon local rules and customs, and they must be settled there, we will trust to a jury of our countrymen and to the mode of procedure in our courts, our interests, our homes, our whole possessions, much more freely, and with much more confidence than we will trust them to anyone who happens to be appointed to a political position in the government, whether he be Commissioner in a Land Office or Secretary of the Interior, or a clerk who may be deputed to decide upon our disputes."

WHAT MIGHT HAVE BEEN

It is an interesting subject for contemplation as to what would have been the results had only the opening clause been enacted—had only the miners' occupation of the mineral land under local rules and customs been authorized and no provisions made for granting fee title. As the local rules, with the single exception noted, required more or less constant development to hold a claim, would the so-called 'paralysis' of mining camps and districts have been avoided? Would the holding of large areas of patented claims without doing further or continuous development work have been prevented? However, the attitude of Congress was almost wholly that the miners should be enabled to obtain the fee title. The single exception was the attitude of the Western members who could not see how a satisfactory method of giving the fee title could be arranged. Of these, Mr. Williams, the dissenter from the bill, advanced the only argument against allowing patent:

Under the terms and provisions of this bill, as it seems to me, a person may take a claim according to the local usages and customs of a mining district, and he may file his plat and obtain patent; the title becomes perfect in him, and then he may cease operations upon the claim and he may hold it for an indefinite length of time. He may proceed in the same manner on another claim, and so in this way claims may be acquired by individuals, not for the purpose of mining, but for the purpose of holding until they shall be increased in value by the operations of mines in the immediate neighborhood and vicinity; and in this way property may accumulate in the hands of individuals or in the hands of companies; the business may come to be a monopoly in the hands of corporations or of capitalists, while under the present system, as a general rule, a man must remain in possession of his mine, he must work it, he must make it productive; otherwise he forfeits his right to the claim. I think that this part of the bill which provides for the sale of the mineral lands is exceedingly defective. While I admit that it is the most unobjectionable bill of the kind that I have seen, and perhaps is as perfect as any such bill can be made, but it is because in the nature of things you cannot pass a general act of Congress that will be adopted to the varied circumstances and conditions and interests of the different localities upon the Pacific coast, but if you have a rule that applies to one it may operate with injury and injustice to another. I admit, too, that it would be desirable if titles could be obtained to these mining claims, as titles can be obtained to agricultural portions of the country; but I insist that it is impracticable at the present time to obtain such titles.

Mr. Sherman said:

I think it is to the interest of the United States to get rid of the mineral lands of the United States, to get them into the hands of private individuals; to give them title by patents in the ordinary way, so that the United States will be divested of all proprietary right over mines. I might produce the opinions of Mr. Benton, Mr. Clay, and many

of the most eminent statesmen of America to show that the title to the mineral lands is of no benefit to the United States. From time to time the principle of disposing of mineral lands, salt lands, iron lands, etc., has been adopted, so that now I believe we have no proprietary title in the United States to any but gold and silver mines. I am therefore in favor of the general principles of the bill, and thus dispose and get rid of the mineral lands of the United States. I believe that it would do more to encourage the settlement of the mining regions, to induce people to go there to make permanent improvements if they can get a good title, than any other measure that can be proposed. It seems to me that no man with our ideas of prudence and care would be willing to build expensive improvements upon lands the title of which he does not possess, and that that general idea is sufficient to induce all of us to vote for this disposition of the mineral lands.

Mr. Stewart said:

It [the bill] provides that when a man has found a vein and improved it to the extent of \$1000 he may get a title. That is the very thing that the tunneling companies want. I know a great many men engaged in that work. I have many constituents engaged in it. They are all pressing for title when they find a vein. They say, if we run into the mountain and take the chances we want the privilege of buying the vein when we discover it.

Mr. Julian said in defense of his bill:

Years ago we adopted the policy of leasing those mineral lands [the copper and lead mines of Michigan], and retaining the fee in the National Government. The result was an utter failure, financial and otherwise. We established at length the policy of survey and sale. The moment we instituted this policy of survey and sale order began to bear rule in the mining regions, sober and intelligent citizens became purchasers and settlers, and organized and prosperous communities were established.

John A. Kasson, representative from Iowa, proposed as an amendment the sale and patent not of the mine, but of the *use* of the mine. He stated that he was in favor of the United States retaining the fee title to mining property, also that it should have a right to regulate the production. The amendment was to be made active by the following section:

That Congress reserves the right of forfeiture and of re-disposition of all claims patented under the provisions of this act, which shall not be in good faith developed, used, and worked within three years from date of such patent, and with reasonable continuity thereafter; and to provide all rules, regulations, and conditions for ascertaining the same and relating thereto; and if any such claim shall be abandoned, the same shall be thereby forfeited, and may be again patented to any other claimant on the same terms as before, * * * and Congress further reserves the right to adjust by general law, in any mining district, any discrepancies, irregularities, or uncertainties touching the character and management of mining claims.

He concluded his remarks with the following statement: "The great object of the Government should be to develop the mineral resources of that part of the country; and in doing that it can best be accomplished by providing that they shall not absorb these lodes and veins and hold them, as they do the public lands of the United States, for purposes of speculation, but they shall go and continue in good faith to develop them. If they do that, then the title will be granted; if they do not, the title reverts to the United States. Unless this is done, I see no safety in passing the bill as it comes from the Senate." This amendment was objected to without discussion, for, as said before, the sentiment of Congress was almost unanimous that the miners should have their fee title, if possible. Today, such an amendment would provoke a profound discussion, in which the 'paralysis' of mining districts and the value of throwing land open to further prospecting and development that is now held idle under patent, would be balanced on one hand by the effect of the amendment upon the investment of capital and the making of large-scale permanent improvements on the other hand.

DEVELOPMENT OF PRACTICE

The act of 1866 met at once with the general approval of the miners, especially the opening section confirming their possessory rights. During the first 18 months the number of applications for survey and patent was not large, owing to a lack of knowledge of just how to pro-

ceed in the details. But gradually the Land Department evolved a set of regulations and the number of applications kept increasing.

The success and increasing satisfaction in obtaining the fee title to lode claims led to the desire for a law authorizing fee title to placer claims. Many of these were used partly as gold diggings, partly for agricultural purposes, and partly as a home site. Naturally there was as strong a desire to obtain patent on the part of their owners as there was on the part of the lode-claim owners who had invested large sums in improvements. On December 13, 1869, A. A. Sargent, representative from California, introduced H. R. bill No. 562 to give title to placer claims, giving it the name, 'An act to amend an act granting the rights of way to ditch and canal owners over the public lands, and for other purposes.' It was considered by the House on March 17, 1870, when Mr. Sargent explained the purpose of the bill, which, in the language of the bill and the present statute, is, "That claims usually called 'placers', including all forms of deposit, excepting rock in place, shall be subject to entry and patent under this act, under like circumstances and conditions, and upon similar proceedings, as are provided for vein or lode claims." Mr. Julian, still smarting under his failures and rebuffs of four years before, was at once upon his feet. Referring to the original act, he said that "It had a false title, calculated to mislead every man who read it; and under a false title it was passed through the Senate and the House, without opportunity for any thorough discussion of its propositions. It not only had a false title, but I hold that it was based upon false principles of legislation." Following which he launched into a general tirade against the bill without producing any definite arguments. After a few favorable remarks by others and some amendment it was passed by the House.

Mr. Stewart reported the bill in the Senate from the Committee on Mines and Mining on March 22, 1870. Later, after some desultory discussion regarding certain amendments which were added, the Senate passed the bill. The House refused to accept the amendments and the bill was sent a conference committee of both houses, from which it emerged in an acceptable form on June 28. On July 9, 1870, it became a law through the approval of the President.

THE PLACER LAW

The act of July 9, 1870, has been called the 'placer-mining act' because it related to placer claims only. It provided that the price should be \$2.50 per acre and that two or more persons or associations could make joint entry, but no person or association was to take up more than 160 acres in one claim. Nothing other than this was said as to the size of the claim or how many claims could be located by one person—that was to be left to local rules. The later act of 1872 limited the claim of a single individual to 20 acres, and proportionately for each individual in an association up to the maximum of 160 acres. The clause that two or more persons or associations of persons having contiguous claims could make joint entry—the clause allowing 'association' placer claims—was stricken out in the Senate on the motion of Mr. Harlan of Iowa on grounds that it might allow a species of monopoly of mineral land. But in the conference this clause was put back in the bill at the instance of the House. It will be noted that the bill read, just as retained in the present statute: "Claims usually called 'placers', including all forms of deposit, except veins of quartz, or other rock in place." Why was the bill not more specific in its wording, so that confusion between what should be located as a lode and what as a placer could be avoided? In 1870 a placer meant only a deposit of gravel containing gold, either surface diggings or the deep-lying gravel deposits. But the framers of the act, wishing to extend the boon of fee title to all miners and all mineral deposits, added the all-inclusive "including all forms of deposit, excepting veins of quartz, or other rock in place." They undoubtedly meant all deposits which could not be located as so many feet in length along a lode and which could not claim apex rights. With the discovery

and location of deposits of 'vein origin' or lode formation, in which so many feet in length of a lode could not be claimed and which were not properly subject to apex rights, the idea became defective. Recourse was then had to the language of the statute, both regarding lodes and placers. In this way there have been formulated certain rules* as to what is to be patented as a lode and what as a placer as viewed by the Land Department. These are liable to be upset or changed at any time by court decisions as to what constitutes a lode or placer, and by the coming to light of some deposit having a geologic occurrence of such new and novel form that it cannot be correlated to either class of deposit under the present rules. However, I believe that the indefiniteness of the statute, so far as it tended to all inclusiveness, is good. Applications for patent are constantly being made on substances and types of deposits that well informed mining engineers have never heard of. It is a safety measure by which the miner has been enabled to get his patent, no matter what his deposit was like. And certainly, the Government can afford to part with a small amount of its resources, rather than that an honest and deserving applicant of small means beyond the hope of original and remedial legislation should have the work or hopes or savings of years swept away because the law just fell short of including him. It is true that congressional legislation can extend the placer act to any form of deposit, and so it did in three distinct subsequent cases, those of building stone, petroleum, and salt deposits. But these were mainly at the behest of bodies of men who waited with bated breath to learn if their rights would receive full protection. There can be one form of location to cover both classes of deposits only after the apex law has been abolished, after all attempts to require the claim to be located with the lode in a particular position has been abrogated, and after the association clause has been annulled to reduce all placer claims to the same maximum area as lode claims.

A bill was introduced by Mr. Stewart at the next session of Congress 'To define and protect the rights of miners and to encourage the development of mines.' This bill with some small changes was the same as that which became the act of 1873. Mr. Stewart made the following explanation: "This bill makes no change in the principles of legislation heretofore had as to mining claims, except that it limits in certain instances the rights of miners to make laws for themselves and defines the shape of their claims more definitely. It is a bill that has been sent out five or six times in various forms through the mining states and territories." The bill involved three ideas: to harmonize under one general system the main features of the thousand and one sets of district regulations to restrict the miners in any district from making regulations that would not work in step with other regulations and statutes, and finally to build up the mining law into a good working machine. The bill passed the Senate after a very brief discussion. In the House Mr. Julian was gone, but the bill failed through want of time to consider, even though the Committee on Mines and Mining was ready to report favorably on the bill through its introduction by Mr. Sargent.

REVISION OF THE LAW

The opening of the next session of Congress saw the old guard at it again with hammer and tongs. Mr. Sargent introduced the bill into the House as H. R. No. 1016, where it was discussed and passed on January 23, 1872. Reaching the Senate, it was amended by Mr. Stewart, who said:

I wish to state that in the first instance the miners legislated for themselves. Congress finally in 1866 passed a bill embodying many of the principles of this bill, and from that time to this the Land Office has been operating under it, and for the last three years we have been attempting to codify it and bring it into a shape that will be satisfactory and more certain and correct abuses. Last year a bill was introduced here and passed which was quite similar to this. A bill has passed the House which is similar to the one that was passed here last winter. Since its passage by the House the delegates from the territories and those familiar with mining rules have had a great many meetings

over this bill in connection with the Committee on Mines and Mining, and the result is a codification, which is the best they can do. I believe it will meet with universal favor. This is the best we can get with all the experience we can bring to bear. It is no one man's work, but it is the work of a great many men interested in this business.

On April 16, the bill passed the Senate under the title of 'An act to promote the development of the mining resources of the United States,' and on May 10, 1872, was signed by the President.

THE FINAL ACT

The act of May 10, 1872, the third and final act and our present mining law, changed the size of a lode claim from the heretofore unspecified width to a maximum of 300 ft. on each side of the vein or lode. It also changed the maximum length that could be taken up by a person or association to 1500 ft. along the lode, instead of 200 ft. for each individual and a maximum of 3000 ft. for an association. The bill as first introduced by Mr. Stewart in 1871 provided 200 ft. in length for each locator and 3000 ft. for an association just as the act of 1866, but allowed the maximum width of 300 ft. on each side of the lode; and in this form it passed the House in 1872. But Mr. Stewart and his associates afterward changed it while in the hands of the Senate committee to give a maximum length of 1500 ft. to both an individual and an association. Mr. Stewart explained this as follows:

In the act of 1866, it is true, the locator was confined to 200 ft., and 200 ft. additional for the discoverer of the lode, making 400 ft. It allowed them to unite in companies until they got 3000 ft. In practical operations it is thought by the delegates generally, and that is the experience, that 3000 ft. is longer than can be worked at one place conveniently, but 1500 ft. makes a very reasonable claim. The practice under the other law was for them to put in fictitious names and buy them out, and you could not prevent them from doing it. This matter was discussed considerably, and we had several meetings on this point, and the committee thought it best to let them do directly what was reasonable, and not have them do anything indirectly.

The act provided for the present annual labor or assessment work of \$100 upon each claim, which matter the act of 1866 had left wholly to the district regulations. Mr. Stewart's original bill of 1871 required labor to the amount of \$25 for each individual holding or location of 200 ft. Mr. Cole, senator from California, proposed to require annual labor on patented claims as well as unpatented ones by adding the three words in italics to what is now the present wording of the law: "and upon a failure to comply with these conditions [the performance of annual labor], the claim or mine upon which such failure occurred shall be open to re-location in the same manner as if no location of the same had ever been made *or patent issued*." He said: "The danger we are under in this country, where we have the richest mines that can be found in the world perhaps, is that they may be purchased up at these government rates in large tracts or quantities. We wish to avoid that very thing, and require the miner to use some little diligence and exertion in the working of his mine or the mine-owner to expend some industry or capital upon it, or else leave it subject to a beneficial use by some other party." Mr. Stewart replied to this: "Requiring work to be done after the patent has been issued would destroy all the virtue of your patent. The object of the patent is to give title; it cuts off all uncertain title; if the person wants to improve a claim he can go and buy it, and it becomes private property, and it is certainly the best policy to have any kind of property improved that it shall become private property. Men think more of a patented claim than they do of one that is not patented. They will spend millions in prospecting a patented claim where they will not spend hundreds of dollars to prospect a claim where the title is uncertain and liable to be disturbed by somebody outside. A patent title is the best for mining operations. Now, for want of a more definite rule the whole region is in litigation. Every man who goes from here West to locate a claim finds so much local legislation which is uncertain that he is discouraged; he finds the neighborhood in litigation." The amendment requiring annual labor upon patented claims

*Mining Law for the Prospector, Miner, and Engineer, H. W. MacFarren, page 87.

was rejected. The act reduced the amount of improvements required upon a claim to secure patent from \$1000 to \$500. It provided for the location of tunnel sites, mill sites, veins within placers, and for a number of important details.

MINOR CHANGES

No legislation and no modifications, except by Land Department regulation and court construction of the statutes, has since been made that can be considered of importance. The following is the substance of the more important subsequent acts: The period of annual labor shall commence on January 1, following location [January 22, 1880]. Building stone may be entered as placer [August 4, 1892]. Lands containing petroleum may be entered as placer [February 11, 1897]. Lands valuable for salt springs or salt deposits may be entered as placer [January 31, 1901].

It was fitting that the honor of signing the first mining act as President of the United States should fall to Andrew Johnson. In 1846, Mr. Johnson as a representative from Tennessee introduced the first homestead bill in Congress. For 16 years until its passage and approval by Abraham Lincoln in 1862, he labored so unceasingly for it with the assistance of such men as Webster, Seward, Douglas, and Horace Greeley, and against the other representatives of his own Southland, that he achieved national fame as the great champion of the homestead bill. The homestead act and the mining acts have been alike in principle and doctrine. One gave free land to the landless individual who would settle upon the land and improve it, and there create a home and subsistence for himself and his family. The other by the system of free mining encouraged the individual to go forth and try his luck and seek his own aggrandizement upon the public domain. Both have added vastly to the wealth and prosperity of the nation. Both were an appeal to the man of more time and muscular ability than means and profitable business connections. The principal beneficiary under the mining acts has been the poor man. H. F. Bain has said*: "We are not aware of any great successes attained by the development of virgin mineral resources that have not been the result of endeavor in the first instance by men who had all to gain and nothing to lose. Prospecting and initial development are essentially functions of the poor man, and the law that does not give the man of small means a chance distinctly limits the expansion of industry." Over the whole of the West is found the man with claims who goes forth each year to do his annual labor or assessment work. If he has no dependents upon his income, he may spend several months each year hunting for signs of mineral and driving his shafts and adits. If he has a family to support he may spend only a few weeks. His task may be hard and his hope deferred ten times over, but still he persists with sublime faith. He knows that in every city of the West are magnificent residences and handsome office buildings and in every fertile valley are fine ranches that are monuments to the fact that men even more humble, more lowly, more unlearned than himself have 'struck it rich.' Examine the abstracts of title of any mining claim and you will find that the locator has held it for years and that there are no 'dummy entrymen' under the mining acts—unless we consider locators of association placer claims as such—and exceptionally few corporation locations. A touch of sentiment is found in these abstracts, for the first quit-claim deed of a claim having a feminine name usually shows that it was named after the better half of the locator.

THE LAW AND THE PROSPECTOR

The true worth and greatness of a law is not measured by the material prosperity it may bring. A law that raises up trusts but produces a nation of slaves, tenants, and wage-earners may increase the wealth of a nation, but a law that clearly shows and gives the individual of small order a chance to raise himself as well as to add to the nation's prosperity is a law of which all may be proud. Would any system of selling the mineral lands as so much land, any

system of Government exploration and ownership, or any leasehold system with onerous terms of development have attained this end? Perhaps a leasehold system with convenient and easy terms of development would, but before approving of it for metalliferous minerals, many things should be known. Will it send an army of prospectors into the mountains and deserts? Will it honeycomb the mineral lands with evidences of where a great body of adventurous men have spent their surplus time and energy in the effort to make a stake for themselves? Will it cause them to dig and starve and thirst and freeze for the fifteen or twenty-five years of individual effort that Mr. Stewart, even in 1866, said it took to find and make a mine? Will it keep them hammering away at the face of the drift, until, 'down to their last bean,' they break into a rich body of mineral? Or will it drive from Alaska the 'sour dough' who is happiest when exploring some creek 'where no white man has ever been before,' and from off the Nevada desert the knight of the narrow-gauge mule and the 'dutch oven' who will be peculiarly contented if he finds a spring of sweet water at the end of the day's journey? If the leasehold system will attract capital and induce extensive improvements equally as well as the present system, but will render the prospector's playground more attractive to him and cause him to go forth and dig with greater zeal, then we want the leasehold system, or any system that will produce such desirable results.

What a wonderful act it has been. Child of a thousand regulations scattered over the Western Empire, born in an atmosphere of hostility far from its native hills, conceived by strong and fearless men and brought forth by a series of masterly forced marches, baptized in the fire of congressional battle, even its framers knew not with what an enduring act they wrought as they brought forth something that others of learning and experience had declared impossible. It is imperfect—so they said in their sincerity and humility at its birth. For six years they nursed it and added to it until it could stand upright, and then made no boast, only saying, 'We have done our best, we can do no more now.' Can they, by any stretch of imagination, be expected to have believed it would stand without change for forty years? Or to so successfully pass through the ordeal that those forty years have brought? And yet today, with critics and scolds on every hand, there is only one specific improvement—the abolishment of the apex right—upon which there is any pretence toward agreement. Why is it that with all the pro and con about the mining law, no specific and substantial improvement beyond the abolition of the apex right has been submitted, or at least none is on general and accepted record? Is it not that it is felt, if not admitted, that the mining law can be amended for the better; but need not be abolished?

A fact that stands out prominently in public-land history is that claimants of public lands under any unperfected rights, and a large portion of those closely allied to that class, are always against change in the laws. They say, "We are satisfied with the law, we don't want it changed," meaning that they understand the present law and wish to perfect their existing rights under it, and feeling that a change in the law will not help, but in nine cases out of ten will cause them serious loss and trouble or hinder their future operations. Therefore, it cannot be expected that those men who 'have claims' and the allied interests will take kindly to any innovation. It is also a well known fact that Congress is conservative, especially in public-land legislation. If the mining acts must become as ill-suited to conditions as the other public-land acts are before they are repealed or remodeled, then our present mining acts are still in their vigorous youth. It is generally understood now that, owing to the peculiar public sentiment at present regarding public-land matters and public resources, Congress does not wish to take any more action on questions relating to the public lands than may be absolutely necessary. All these conditions lead us to the belief that the defects in the mining laws should be met by strengthening the organic act and providing for new conditions, but without altering the doctrines or principles along which

*Editorial in *Mining and Scientific Press*, January 7, 1911.

the laws themselves have been operating. It should not be made harder to locate, hold, develop, or sell a claim than it now is for the man who tries to live up to the letter and spirit of the present law. But the claim-owner should be made to live up to the spirit and letter of the law, and the law should be kept so broad that the miner may not be interfered with by technicalities.

NEEDED CHANGES

First in the list of proposed changes is the apex question. I do not believe that the retention or repeal of this feature will increase or decrease by a fraction of one per cent the number of mines found or opened. Its repeal will stop a lot of expensive litigation, but will not stop that upon claims already located, unless the repeal is made retroactive. To make the repeal retroactive would be to establish a new principle in legislation that would be generally undesirable, and I hope it will never be done. Judging by the record of the past, a goodly number of mining attorneys, engineers, experts, and witnesses now employed in apex suits will find, if the apex law is repealed, just as remunerative employment in suits for underground trespass and ore-stealing as at present. The good to come from repealing the apex law is largely that provisions could then be made for locating lode or quartz claims as so much land with any kind of boundaries, end lines would not need to be parallel, and the claim would not require adjustment to the outcropping lode; however, this would not do away with adverse claims and other troubles from overlapping claims. It should always be borne in mind that the apex right is a distinct feature unrelated to the remainder of the law, except as previously suggested.

The next proposed change, one that can readily be made and that should work no hardship, is a codification of the state laws and national statutes. This should include working out new laws, and, when enacted into the federal statutes—into a new mining act—should serve two purposes: (1) through uniformity and resulting wide comprehension of all the necessary details, to do away with all necessity of state statutes on the subject of locating and holding a claim, of which the present exceeding great diversity does not effect a single good end; (2) to enable the simplifying and strengthening of the weak and ill-suited parts of the present law without working any hardships on the miner or embodying any new doctrine. This last would relate to simplifying the method of laying out a claim if the apex law was repealed, to requiring development in such a way that 'paper' locations would be of no avail, to making it easy for another to locate a claim upon which the required development work had not been done, to requiring the claim to be kept marked so that it can be readily found and identified, and similar measures. Also, allied to the second, is the formulating of suitable laws for exploring and developing peculiar deposits and such deposits as gas, oil, phosphate, and others, and the location and development of lands upon which no mineral discovery can be made except by and after extensive development. Following this the question of leasing metalliferous mineral deposits may be considered. Likewise, the effort may be made to find some way to prevent the 'paralysis' of mining districts, both with respect to claims patented heretofore and hereafter; but this is a dangerous subject and one that needs careful consideration.

METHOD OF REVISION

In case an attempt is made to improve the mining laws along these lines, the greatest trouble will be caused through inability to know where to stop. To some the revision will not be carried far enough; to others it will be carried too far; nobody will be quite satisfied, and if the revision is carried too far and the law is not broad enough, many with unperfected rights will be caught between the millstones of adverse legislation, and future prospecting will be retarded. It is well known that the miner will fight to retain a claim that may be acknowledged to have little value, and that no topographical or climatic conditions will hinder him from prospecting and locating

claims. But the truth is not so generally known that the mine hunter cannot brook restraint by 'red tape' and technicalities of legislation and Government control in locating claims. If he cannot slap down his location and go to digging without being interfered with by a lot of regulations in which he is able to see no wisdom or expediency, he at once gets discouraged and goes away without making locations. It is said that some other class of people will be willing to undergo the trouble required to locate the claims and will take up the ground. Before accepting this, go into the mineral districts and inspect the unpatented locations. See how unencouraging and unpromising looking they are. Then consider if anyone would go to much trouble to locate the virgin surface, or whether, in a large number of cases, anyone would try to develop this unpromising ground into mines were it not for that contagion caught from acquiring ownership through easy location—a contagion that is unexplainable, but that draws the prospector back year after year.

It is to be hoped that whoever may undertake the revision of the mining laws will bring to bear the same wide and intimate experience, the same abiding respect for the gravity of the subject, and the same hard and careful work that Stewart and his fellow-laborers had, and that they will be guided by the same lofty sentiments and the same wise consideration and respect as were expressed by the statesmen of that day for the individual who skirmishes in advance of the army of capitalists, investors, promoters, engineers, and workmen, and who is the foundation of our mining prosperity.

Mineral Resources of Nigeria

LONDON CORRESPONDENCE

The annual report on Northern Nigerian affairs just issued by the British Colonial Office remarks that the exploitation of the tinfields in Bauchi has already attained considerable proportions, and that a large amount of capital—at least twelve and a half million dollars, says this report—has been invested in the various enterprises. The stanniferous areas are undoubtedly large and valuable, but in several cases company promoters and others have expressed hopes and forecasts which can never be fulfilled. As far as is known at present, tin is to be found in more or less profitable quantities over 9000 square miles of territory, extending from Ningi in the extreme east to Duchin Wei, situated about 40 miles east of Zaria, to the extreme west; and from Liruen-Kano in the north to the Ninkada and Mada districts in the south. Mining leases have been granted over about 12,000 acres and exclusive prospecting licenses over about 355 square miles. Prospecting rights have been granted to 149 prospectors. During the year under review (1910-11) 800 tons of cassiterite was exported. Opinions vary as to the probable future prospects of the tinfield. It is safe to say, however, that the existence of the tin over a large area has been proved, but that up to the present time sufficient prospecting has not been effected to render it possible to draw any conclusion regarding the value of the field as a whole. The report also mentions that rich deposits of galena, containing silver, are known to exist in the province of Muri, and adds that these reefs, which have been to some extent worked by the natives, are now being closely prospected by European engineers. Pockets of native silver have from time to time been discovered in the vicinity of Orifu and Wukari.

The question of transport has been the great trouble. From the nearest available spot on the Niger the so-called Kano main line is being extended across Northern Nigeria. This was planned before the discovery of tin ore and was part and parcel of the general colonial development of the territory. With the finding of tin and the necessity for quicker transport, a special branch line was started from Zaria on the main line to run for about 100 miles to the west and to terminate at the foot of the Bauchi plateau at Warno. The question of labor supplies has also been raised, and many conflicting views are held.

A Convenient Slag Furnace

By J. D. HUBBARD

A description of this slag furnace and the method of reduction of slags obtained from the melting of cyanide precipitate at the Oriental Consolidated Mining Co.'s plant at Taracol, Korea, were given in the February 5, 1910, issue of the *Mining and Scientific Press*. A further description, and details of construction, may be of interest to the profession and assist some one who is confronted with the same problem. In the preceding article the cost per ton of slag treated was given at \$32.89. This was no doubt a shock to the economical, and prevented any further consideration of the furnace, as many could ship their slags to the smelter for a less cost per ton than \$32.89. In actual practice with the furnace it has proved conclusively that the costs were much less. The elimination of coke for fuel (which costs \$30 per ton at Taracol) and the substitution of charcoal, also the reduced labor and other costs, have resulted in lowering the net cost to \$7.51 per ton of slag treated, as follows:

Charcoal	\$4.50
Labor	1.66
Power	0.17
Iron, etc.	0.12
Firebrick	0.84
Depreciation (25%)	0.22
Total	\$7.51

This cost is less than the treatment charge at the smelter, to say nothing of freight. Adding the advantages of local treatment products where possible, and the high net extraction obtained on a refractory slag, this slag furnace offers advantages.

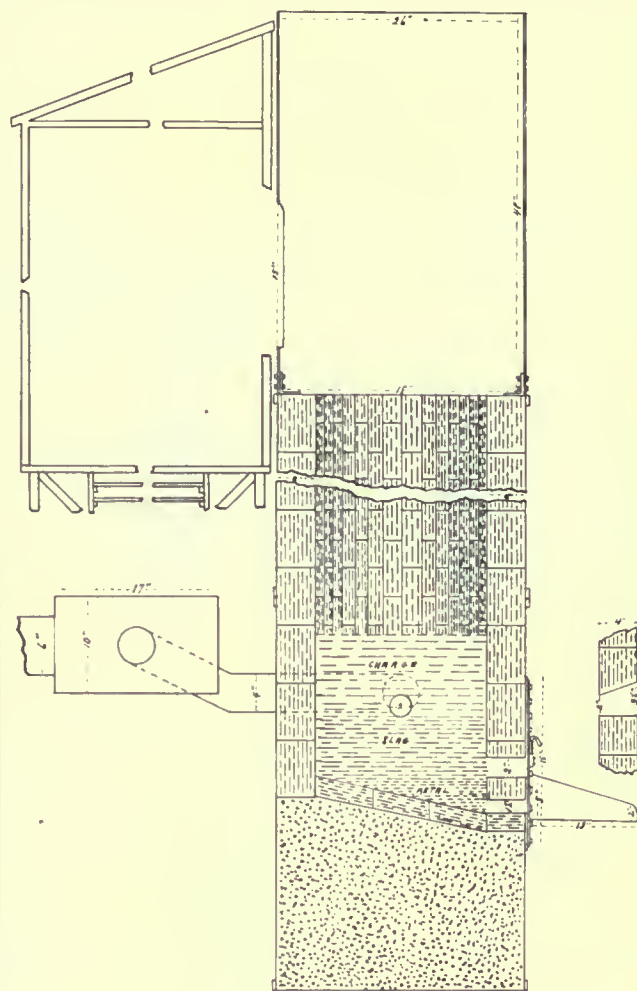

Of course, the labor item would be cheaper in the Orient or other low-priced labor countries than in the United States; but, on the other hand, fuel, especially where oil can be used, would be much cheaper than in the States. One-half ton of coke is amply sufficient to reduce one ton of the most refractory slag. Where the slags contain only shot gold or silver, re-grinding in a clean-up barrel with quicksilver would practically recover all of the precious metals, but in most cases where they are held in matte, drippings from crucibles, scales from the roasting-pan, etc., from a low-grade bullion product, it necessarily follows that a different metallurgical process must be employed. The cleaning property of lead on a charge is too well known to require reiteration. It follows that if the proper amount of lead be added to a slag containing gold and silver in a metallic form, a satisfactory elimination of gold and silver will result. Acting upon this principle, this slag furnace was evolved and perfected as far as possible. It has proved quite satisfactory in Korea and has saved the Oriental Consolidated Mines Co., where it was developed and put in use, much money.

The plan of the furnace is simple, as can be seen by the drawing, and any small blacksmith shop would be equal to the construction of one. The furnace shown in the drawing is large enough to treat two tons of slag in ten hours. But the capacity can easily be increased by proportionately increasing the dimensions of the furnace. The shell may be made of any old sheet iron available, as its use is merely to hold the inside lining in shape. The shell will last indefinitely if the lining is kept intact. It is always necessary to renew a portion of the lining after every heat. At first firebrick alone was used for the lining, but I found that a mixture of red clay, broken fragments of graphite crucibles, and discarded firebrick, all broken to pass a 1-in. ring, was just as effective for lining, and of course much cheaper. The only firebrick used are to line draft-holes and tap.

Another point of economy was that it was not necessary to buy a single pound of lead for use in the furnace, as slag from the assay office, which always contains unreduced litharge as well as borax and sodium bicarbonate,

both useful in liquefying slags, was used for the purpose. The charcoal used as fuel brought all the lead down in good shape.

The method of treatment was fully described in the article mentioned. Briefly, it is to mix the slag with the required amount of fuel and assay slag, and feed it in slowly at the top of the furnace. A proper amount of forced draft must be maintained, and care taken not to overfeed the furnace. A roof over the feed platform is quite desirable for protection from red-hot cinders and particles of melted slag. It is essential to keep the draft-hole in good shape by reducing the diameter of the inside end of the opening, as shown in the drawing. The sharp angle formed

A CONVENIENT SLAG FURNACE.

by the top brick prevents the slag from backing up in the draft-hole. Also the hinged door at the top or some other arrangement for opening and removing the residue of the charge at the end of the heat is necessary, so as to leave a clean furnace for the next charge.

The actual extraction by bullion returns, and assaying the final slag at Taracol, Korea, was 98% on over \$40,000 worth of slag. The bullion produced is necessarily base, averaging at Taracol 34.45 gold and 259.51 silver. There is enough excess lead in the base bullion for satisfactory cupellation, yielding clean doré bullion. A shallow cupel, 3 in. deep in the centre and 10 in. wide across the top, is a satisfactory size to use, and does not require a very large cupelling furnace. The cupelling furnace may be of simple construction, care being taken, however, to have it sufficiently large on the inside to allow plenty of fuel around the muffle. The muffle should be large enough to admit two cupels 3 by 10 in. Each cupel will hold 25 lb. of bullion. A patent has been applied for on this furnace to protect it from speculators, but it is freely offered to metallurgists and mining companies who may find it useful. My thanks are due to W. H. Aldridge, master mechanic, and B. Pedersen, his assistant, for valuable hints given in the construction of this furnace.

The Chilean Nitrate Industry

The nitrate industry of Chile enjoyed a prosperous year during 1911, according to consular reports from Iquique, with exports at about 2,000,000 Spanish quintals, or 101,400 tons, above that of 1910 and an advance of 5 to 10% in prices. This is owing quite largely to the work done by the Nitrate Propaganda Association in Europe and the United States. Several new nitrate works have been opened during the year, and others have been enlarged. There is a bright outlook for this industry during 1912, which means that business in general will be good in Chile during that time, for this is the important industry of the country. The nitrate industry is not only an important factor in the commercial interests of the country, but it supplies a very large part of the nation's revenues, as may be seen from the following table:

Periods.	Amount.
1880 to 1884.....	\$ 26,364,415
1885 to 1889.....	40,724,145
1890 to 1894.....	58,533,795
1895 to 1899.....	74,886,320
1900 to 1904.....	86,696,625
1905 to 1909.....	113,866,130
1910.....	28,977,725
Estimate for 1911.....	29,000,000

Total for 21 years.....\$459,249,155

As showing the comparative importance of the several Chilean ports from which nitrate is shipped, the following schedule gives the quantities (in quintals) exported during the first nine months of 1911: Province of Tarapaca—Pisagua, 1,938,142; Junin, 1,127,500; Caleta Buena, 3,675,850; Iquique, 8,011,983; total, 14,753,475. Province of Antofagasta—Tocopilla, 4,615,572; Mejillones, 4,920,049; Antofagasta, 4,172,119; Caleta Coloso, 2,011,927; Tal-tal, 4,146,904; total, 19,866,571.

The market price of nitrate of soda declined during November 1911. The first part of that month there were sellers at \$1.95 American gold per Spanish quintal for immediate delivery alongside vessel, and buyers at \$1.94 gold. The last part of November, sales were made at \$1.89 American gold per quintal, and for delivery during all of 1912 the price was \$1.85 American. On December 6 there were sellers at \$1.84 and no buyers in the market. There is no explanation offered for this slump, but as it has been a slow steady drop, it is probably more than a temporary fluctuation. There is a scarcity of labor in the pampas (plains), and many of the nitrate works are advertising for laborers in the daily papers. Gangs of men are being brought up from the south of Chile to supply the demand.

The Antofagasta pampa seems to be the more prosperous at present, as the grounds are newer, whereas in the Province of Tarapaca many of the grounds being worked are partly exhausted. The Government of Chile is contemplating the auction of public nitrate lands in Tarapaca, which, although adjacent to existing nitrate extraction plants, are large enough to warrant the construction of new works. The law authorizing this auction is under discussion, but has not passed the Congress, as it is being strongly opposed by the Antofagasta interests, on account of the fact that a part of the proceeds are to be expended in public works in the Province of Tarapaca. The minimum prices specified in the bill are considered extraordinarily high in view of the low grade of the 'caliche' (native saltpeter), of which some lots run as low as 10 or 15% nitrate, being the poorest quality which has been offered for sale so far. In consequence, it is not expected that there will be many purchasers; in fact, it is doubtful if a sale will be made at these prices. Maps of the grounds are not printed, but may be seen in the office of the Asocia-ción Salitreria de Propaganda, in Iquique, and in the offices of the Secretaría del Consere Salitrero, and of the Delegación Fiscal in Santiago, Chile.

The Chilean Government has collected an export tax of about \$12.34 per metric ton (2204.6 lb.) since October 1880 with the above result, and of late the Government has been discussing the advisability of increasing the tax. It is claimed the supply is sufficient for many years at an even greater production than at present, which means much for the future of the country and its people. On the strength of this, extensive internal and port improvements are planned for the next few years.

The Gee Centrifugal Concentrator

By EDWARD WALKER

Some attention is being attracted in Cornwall at present to a centrifugal machine invented by W. J. Gee, originally intended for the purpose of rapidly settling china-clay slime, but more recently proposed to be applied in concentrating metallic slime. I am not aware that the machine is in actual practice, but as the principle is of interest, I will give a short account. The machine as applied to settling china-clay slime consists of a vertical cylinder revolving at a peripheral speed of 100 to 200 ft. per second. Inside are fixed vertical radial vanes held in place by vertical rods and removable liners. The slime is fed at the top, and the coarser and heavier particles are caused at once to fly to the periphery and build themselves into a wall. As the water gradually passes down the sides, the finer particles range themselves to the periphery. The water also forms itself into a wall, and when its internal surface comes to the edge of the bottom plate, it commences to discharge through orifices. The rate of feed and of revolution are so adjusted that the effluent is quite clear. After a time the machine is stopped, the liners and adhering slime removed, and other liners put in their place. The cakes of slime may be divided into as many grades as desired, it being remembered that the particles are largest at the upper end and finest at the bottom end. The inventor claims that the classification of china-clay is done more efficiently than in the usual 'drags' and settling pits, that the removal of water is more complete, and that the time occupied is greatly reduced. The high velocity of rotation is a disadvantage and involves the use of special foundations and bearings. The fact that the working is intermittent may also be considered as against the process, not because of the actual time lost, but on account of the labor required.

When applying the principle in the concentration of slime, a different motion is required. The inventor makes the vanes independent of the shell, and revolves them in the same direction and at a rather higher speed. The separation of the mineral from the gangue could not be effected at all unless the feed is accurately sized, so that the finer the slime the better. The difference in the speed of revolution of the vanes causes a washing effect at the point of deposition, so that the particles of lower specific gravity are kept in suspension and are eventually removed with the effluent water. Many adjustments will be required, namely, the speed of the cylinder and of the vanes, the distance of the vanes from the periphery, and the rate of feed. In carrying out the process, the feed would be stopped when a sufficient amount of concentrate had accumulated, and clean water substituted, so as to remove all the gangue still in the cylinder; afterward the concentrate is removed by retarding the revolution of the cylinder but not of the vanes. If all these delicate adjustments can be easily made, and if not too much skilled labor is required, the process may prove applicable to the treatment of tin or copper slime, where there is plenty of room for improvement in present practice.

PRUSSIA owns many of the mines within its borders, but these state-owned properties are not great sources of profit. During the past year the gross receipts were M.290,073,320 and expenses M.267,427,097. Of the remainder, M.16,735,950 was written off for ordinary expenses, leaving a net revenue of M.5,910,273 for the year.

Smelter Building in Chile

By FRANK LANGFORD

Chile is not a Latin-American country in the common North American sense of the term, either in climate, habits, or temperament of its people. It has a large element of the best Spanish stock, tempered by two hundred years of serious-minded conquest of a rugged and arduous country, difficult of development in comparison with our own prairies or mountains. It has a considerable mixture of the same class of pioneers who came to California; many of them sailing for California in the fifties, and, finding the coast of Chile attractive, remained there. It also has a large German element, of the type of our own sturdy agriculturists who have done so much to 'make Milwaukee famous.' Chile has, besides, a large native Indian element of the strongest and most industrious type, many of whom have become skilled mechanics and farmers.

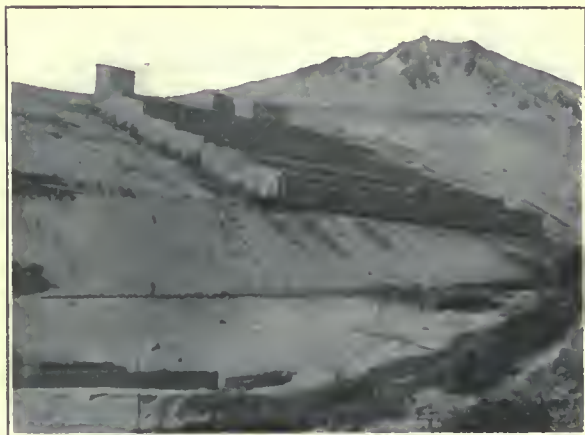

The business men of Chile are quite as reasonable to deal with as our own, and will sacrifice far more for the development of resources than we individually will do. For example, the Braden company had to build its railroad 36 kilometres and its high-tension electric transmission line 26 kilometres through the ranch of Don Carlos Irrarrazaval. For these rights of way a merely nominal charge was made. The same might be said of nearly all of the numbers of *hacendados* who opened their farms to permanent occupation and the free passage of thousands of workmen and teams, in the construction of canals, railroads, electric lines, and plants, and under the unusual condition that much of the work was actually done, and all of it known to be necessary, before the prices were fixed. Here is the difference between the Latin and the 'Gringo': to buy required property at a reasonable figure in the States it must not leak out that anything is to be done, while in Chile it is required to be demonstrated that something is going to be done, before the required privilege can be had, in many cases.

The 'graft' that so much is heard about in Latin countries does not exist in Chile to hinder the investment of outside capital. In my two years as manager of the Braden Copper Co., during the busiest construction period, not a dollar was 'paid out to 'grease wheels' of any kind; and during that time 25,000 tons of machinery and materials was landed, passed through the customs, and moved over the state railroads to our own railroad, and to ox-carts. An ox-cart is not to be sniffed at. A two-wheel bull-cart carried seven tons at a load, over 75 kilometres of mountain road, at \$9 per ton. The regular loads of three tons to each cart were, of course, carried at a much lower rate, where feed is as high as it is in California. The Chileno is a splendid horseman, but has found the ox to be the best and most profitable draft animal. He is not slow, like Tolstoi's ox or the Mexican ox, but travels as fast with the plough as our horses do.

The Chileno workman is industrious, working long hours cheerfully if paid for it. He is often keen to pick up suggestions. As an illustration: the cart road to the mines was impassable six months of the year, and before the completion of our railroad our winter stock of Huntington mill die-rings ran short; the supply had arrived in the country too late in the fall to move up. These rings, weighing a ton each and 6 ft. in diameter, were placed on the cart wheels as tires, over the regular tires, keyed up with wooden wedges, and rolled into camp 75 kilometres through mud and snow knee deep, with the usual string of oxen for a three-ton load. At the same time, a bridge on the cart-road crossing the Coya river gorge had to be taken out to permit the blasting of a heavy rock cut on the railroad construction a thousand feet vertically above it. The ox-cart with its novel broad tires must cross the bridge or the mill would be shut down. The railroad contractors were ready to put off the big blast, though the bulls might be several days coming up. The generally expedient plan of not waiting for anything was followed; the rock blast was put off

and completely filled the canyon at the bridge-site, making a rock bridge of boulders as big as a house, with the river running under it, that was available at once and has been used ever since.

Here, in the mountains of the roughest country in the world, and side by side with the ox and the wooden plow, the Braden Copper Co. has one of the most complete mining installations anywhere to be found, including its own power canal, diverting a river, and carrying it 13 kilometres in rock-cuts and tunnels, and developing 12,000 hp.; its own railroad 75 kilometres, climbing a mile high in half that distance, with more degrees of curvature than any other railroad in existence; a concentrating plant of steel and concrete to treat 2000 tons of ore per day; its own smelter, an acid plant, and leaching and electrolytic plant; electric haulage underground and to the mill direct without re-handling; its own town, hotels, stores, barracks, schools, and chapel. This development was due primarily to a few

NEW MILL, BRADEN COPPER CO.

men with pioneering courage, like M. Chiapponi, William Braden, Barton Sewell, Mr. Nash, and their associates. After all, it makes no difference whether the incentive was profit, or the strong man's ambition to do a new thing in a new region, or a big thing well.

Mining in Morazan, Salvador

The Monte Mayor Gold & Silver Mining Co., of Salvador, an enterprise composed of Salvadorean and foreign capitalists, has recently denounced what are supposed to be valuable silver and gold-mining properties in the Department of Morazan, Republic of Salvador. The mines lie within a rich mineralized zone of 16 *hectares*, between San Jose del Penon and the San Antonio Guayoto ranches, and 12 well defined gold and silver-bearing veins have been discovered. The mines are at a distance of about two leagues from the celebrated San Sebastian mine and about two and a half leagues from Sociedad. Modern machinery and equipment for working the mines have been ordered abroad and part of it has already been received at the port of La Union. The company proposes to work the ore, which assays \$12 to \$14 gold per ton, by the cyanide process.—*Pan-American Union*.

THE Peruvian Government has granted a concession for a period of two years for the exploration of gold-bearing sands and gold mines along the banks of the Chinchipe river from the point where it enters the Marañon river to its confluence with the Canchis river. The object of the exploration in this territory is to determine the feasibility of establishing on a large scale the exploitation of gold placers and deposits. The tributaries of the Chinchipe river and the islands lying therein are embraced under the terms of the concession.

ARGENTIFEROUS GALENA has been found at Barranea Oscura, in Guatemala, and the discovery has been denounced.

Gold Workings in Central Asia

By ELLSWORTH HUNTINGTON

*At Karbu, in Ladakh [76°E., 34°N.] I found the terraces pitted with numerous inelines, dug for the gold which is contained in the gravels. There I met an English mining engineer prospecting for a mining company. He was disgusted with the meagre quantity of gold; it was not worth looking at, he said. He had found just one thing that interested him; a fragment of good ore said to come from a mine near Lhasa, owned by Buddhist lamas. He was going home to tell his company that Thibet was the place to hunt for gold.

The people of the Karatash valley [81°E., 37°N.]

----- RAILWAYS. BOUNDARIES.

A PART OF CENTRAL ASIA.

herd sheep at the upper end, mine gold at the middle, and farm lower down, below an elevation of 8000 ft. The gold occurs in the gravel terraces, just as in California. The women and children bring the gravel in bags on their backs to the stream, where it is panned by the men in sub-conical wooden bowls eighteen inches in diameter. A miner told me that the sluice where he was working was the common property of twelve men, belonging to five or six families, every member of which, from six years old upward, is engaged in the work. The men own a few fields, but by no means enough to support their families. Their only live-stock is a few donkeys. The profits of the united labor of the twelve and their wives and children during the preceding month had amounted to 200 'tengehs,' or \$10, and during the month before that to \$8. According to the Chinese regulations, all the gold must be turned over to certain native officials, who pay for it what they choose, often only half the real value. The slight return from gold-mining is credible only when one sees the clumsy method of work, the frequency with which a pan of gravel yields nothing, and the deliberation of the movements of the miners. Yet, with the help of their fields, the people manage to live on a dollar or so a month for each man and his family.

The gold-mining town of Sorgak [83°E., 37°N.] lies on the enormous fan delta of gravel which the Niya river

has deposited where it suddenly emerges from the Kwen Lun mountains and crosses the old fault-line to the relatively level basin floor. Sorgak presents the essential features of a mining town in the southwestern part of the United States. Perhaps it is a trifle more barren and unattractive than the worst of our mining towns, but from a distance it gives the same impression of rawness to the traveler. It lies in a basin-shaped valley a quarter of a mile or more from the edge of the deep gorge of the Niya river, whence water must be brought up on the shoulders of the women, or the backs of donkeys. Not a vestige of verdure can be seen; nothing but gravel with dug-outs half buried in it. Here and there a blatantly new shanty with a mud roof and an unseasoned wooden front stands among the older dusker structures. The population of the region is said to be between three and four hundred families, and the total number of men who work as miners, including those who stay only a month or two, is about two thousand a year. The annual output of gold is only \$26,000, or \$13 per man. Thirteen dollars a year does not seem to be a sum calculated to encourage lavish expenditure. Nevertheless, the uncertainties of the miner's life and the possibilities of sudden wealth lead to the same extravagance in central Asia as in western America. The bazaar is surprisingly large and busy, considering the size of the population, and it is filled with idlers. As I walked about to take photographs I counted a hundred and twenty men and boys following close behind me, and there were certainly fifty more sitting idle in places which we passed. I did not count the baby which lay in its eradle in front of a closed shop.

Many of the miners at Sorgak are at work on the top of the great gravel fan, far from the gorge of the river. Accordingly the miners winnow the gravel instead of panning it. When first I saw this primitive process, the gravel was dumped in a conical heap two feet high. With their bare hands, scarred and maimed by frequent cuts, bruises, and sores, a man and a woman moved the heap forward by throwing handful after handful to the top. The finer sand was blown away during the process, and the coarser fragments rolled to the bottom of the cone, where they could be brushed away. Thus the advancing heap was gradually diminished in size, and reduced to a somewhat homogeneous mass of very fine pebbles and coarse sand. At length the miner put this in a wooden pan, and, holding it higher than his head, poured it into a cloth on the ground, thus allowing the wind to blow away part of the remaining sand and pebble. In the midst of the pouring, the young man stopped and began to whistle. "What are you whistling for?" I asked. "For the wind," was the sincere answer.

When the wind had done its work the miner spread the remaining gritty mass thinly over the cloth, and blew it away by mighty blasts from his lungs, beginning on the edge and working inward. All his partners, of both sexes and all ages, or at least as many of them as could find room, gathered around the cloth, and, lying on their stomachs, watched with the traditional gold-miner's excitement for traces of the yellow metal. A little girl pounced on a flake, but that was all. "Only ten cents worth of gold for the morning's work of ten of us," was the discouraged remark of the strong-lunged miner; and his "ten of us" meant only the men who share the mine, not the women and children who had helped.

SEVERAL expeditions have been sent into southern Chile to prospect for petroleum in districts where topography and formations indicate the existence of oil. One of these expeditions recently left for Manao to explore a petroleum field covering 1600 hectares of land. Borings will be made in different places and a full report of the result of the investigation will be submitted in due course.

A COPPER SMELTER has been established at El Teniente, Chile, with a capacity of 20 tons of bar copper per day. The first shipment of 35 tons of bar copper has been made to Liverpool.

*Excerpt from 'The Pulse of Asia.' On the accompanying map the word 'China' marks the approximate position of these deposits.

Discussion

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Insertion of any contribution is determined by its probable interest to the readers of this journal.

Flat-Bottomed Ore-Bins

The Editor:

Sir—Frequently mining journals print articles advising the use of ore-bins having inclined bottoms instead of flat bottoms, and a recent note in the *Mining and Scientific Press* for March 30, 1912, under 'Concentrates' reiterates the statement.

I believe it is very bad practice to make an ore-bin with an inclined bottom. They are more costly to construct, harder to maintain, and are a great waste of space. A flat-bottomed ore-bin will hold approximately twice as much ore as an inclined one, and where do you need storage capacity more than at the mill or reduction plant? I maintain that it is the most important point to have storage capacity. That is where the heart of the mining operations is situated, and it should be the aim of all mine managers to keep the reduction plant running continuously and without loss of time. By the time the ore has reached the mill it is in its best condition for storage, because of its reduced size. The mine manager never knows when something will happen to shut down his supply of ore from the mine; a break-down to the hoist, necessary repairs to the shaft, broken pumps and flooded stations, or serious mishaps to his levels, stopes, and chutes, and, above all, repairs to his crushers. By having a good storage bin at the mill there is always a reserve on hand and frequently the repairs at the mine of any nature can be made without loss of time to the mill. I have seen mills of from 5 to 300 stamps that had such small bin capacity that a delay of 12 hours in putting ore into the bin from the mine would cause a shut-down of all the stamps in the 5-stamp mill and up to 75 stamps in the 300-stamp mill, of from one to twelve hours.

At the Gold Bank mine, in Forbestown, Butte county, California, I had a 60-stamp mill, 40 stamps averaging 2½ tons per day, and 20 stamps averaging 3 tons per day of 24 hours, and without notice I could run the mill to full capacity for ten days, and once by making preparation, I ran the mill to full capacity for 3 weeks without putting a pound of additional ore into the bin. I consider the time gained for making repairs in the mine and hoist of the greatest value. At one time I practically reconstructed the ore-bin for 40 of the stamps without losing a minute of running time for a single stamp; that is, I put in new posts, new main sills, floor sills, floors, and siding. The method pursued was to put in temporary chutes from the track to the bin so the ore would shoot directly over the openings above the feeders. The back part of the ore-bin was uncovered, the bin having been practically emptied before beginning operations (the flat part of the ore-bin being about 16 ft. wide, as I recollect it, from front to back). Just enough ore was carried in the bin at night. Two shovelers at \$2.50 were provided on both day and night shifts. When about two-thirds of the bin was completed from the back toward the front the chutes were taken out and the ore dumped upon the completed floor, and short sections in the front part were taken up one at a time, and new main sills, flooring, and siding put in. The shovelers threw the ore from the completed floor space across the space into the chutes leading from the bin down to the feed hopper; the chute and hopper held enough ore to run five stamps about an hour and a half, which enabled the carpenters to do a lot of work without interfering with the shovelers. As stated above, the work was completed without a minute delay in running the mill.

Too much stress cannot be put on the necessity for large storage capacity where it will do the most good, namely, at the reduction works, and there is no better way than by

making flat-bottomed ore-bins which will hold approximately twice as much as inclined-bottom ore-bins, and ore is then available at any time of emergency with slight additional cost.

HARRY P. STOW.

Oakland, California, April 5.

Magmatic Origin of Ore-Forming Solutions

The Editor:

Sir—*De gustibus non est disputandum!* In your issue of March 16 C. F. Tolman takes issue with A. C. Lawson's criticism of 'Types of Ore Deposits' and develops his conception of the problem. To speak for myself: I enjoyed Mr. Lawson's article as I would enjoy a brilliant after-dinner speech, and found under the unusual surface many an instigation to reflection and a clever reminder of the fact that our ideas on ore deposition are still to a large extent speculative, even if some of our great pioneers laboriously join stone to stone for an ultimately irreprovable foundation.

I do not intend to question for a moment that Mr. Tolman's article contributes a great amount of new and valuable material, nor that his ideas are both original and convincing. But he cites a great many ore deposits to support his theories, and with some of those mentioned I am somewhat familiar, and regret that I cannot quite agree with him. For example, in the Globe district, I cannot see that it is proved beyond doubt that the diabase intrusion here has nothing to do with the ore deposition. F. L. Ransome offered some very good arguments to support his supposition, and even if there is a later acid intrusive that originated the disseminated copper deposit of the Miami district and reworked and enriched the Old Dominion vein, that does not prove that the diabase had nothing to do with the copper in this district. If Mr. Tolman would study some sections of the Old Dominion vein and some of its eastern neighbors, such as the Superior & Boston or Buckeye, he would find deposits that tally closely with Monte Catini in character. There is hardly any doubt but that here, as there, the source of the copper was an extremely basic intrusive. The ore here is marked by plentiful micaceous hematite with chalcopyrite and pyrite. Even rounded boulders of chalcopyrite in soft red gouge are reported from the bottom of the Mallory shaft. Is hematite and micaceous hematite a characteristic of salic or femic rocks? Furthermore, while it is a fact that until now the Old Dominion system of veins has been nearly the only one in the Globe district that has proved to be of economic value, that does not preclude the existence of other veins equally important that have not been proved. In fact, I have every reason to assume that mining around Globe is only in its infancy and that a number of other veins will soon rival the Old Dominion in richness and importance; veins that never received due consideration till now, partly because their outcrops are buried under overthrust masses or Gila conglomerate, and partly because nobody ever believed in them or tried them, and the stampede was going in the other direction.

In the Morenci district ore deposits are localized around two places—Morenci and Metalf—it is true, but the rock is not more acid in these two places than in the rest of the laeolith. The fact is well recognized that the southwest part of the laeolith to the south and west of Morenci is mostly a diorite porphyry and practically devoid of copper deposits. But Metalf is to the north of Morenci, and there are several miles of porphyry between these two places which is fully as acid as in the copper zone, and, nevertheless, no orebodies of importance have been proved there, although search has been made. My opinion is that the great east-west faults have much more to do with the mineralization than has yet been recognized. The Coronado fault antedates the mineralization, and so does, in all probability, the Concentrator fault, and perhaps also the Copper Mountain fault, even if here a later reopening would have to be assumed. The lode system at Morenci is almost a typical fracture-zone due to end-to-end pressure in a fault

block. The Coronado fault passes straight into Metcalf hill, even if it sends off some curved branches in the Santa Rosa country. There is one reason for the localization of the copper, but it is not found in the nature of the intrusive.

The deposits at Bisbee, Mr. Tolman characterizes as "lenses in limestone, unaccompanied by intergrowth of contact minerals and at some distance from the intrusive." I do not believe that Mr. Tolman could prove very many orebodies in Bisbee "away from the intrusive." The Shattuck is a mineralized porphyry dike, plain and simple. J. M. Boutwell, of whose thorough study and careful observation the Bingham report is a splendid example, advocates, as I am told, the theory that the Bisbee orebodies originated in close conjunction with porphyry dikes and sills in the limestone. I pointed out six years ago that the great kaolin masses in connection with the orebodies were altered porphyry dikes, and attempted to and (I thought) succeeded in tracing porphyritic structure from little altered porphyry to the white kaolin masses that blend into orebodies. About a year ago I sketched some observations along the same line for your journal. So much as to the concrete points upon which I do not agree with Mr. Tolman.

As to abstract reasoning—to avoid the word speculation—I believe that the magmatic origin of many deposits is unquestionable. Deposits like Cripple Creek, Braden, and Nacozari, to mention only the extreme and uncontested ones, point plainly in that direction. Even the Globe district affords a splendid example, as against the mineralization by heated ground or surface water. I mean the gradually deepening of the Miami-Inspiration copper belt from about 200 ft. below the surface at Miami, to a covering by more than 1000 ft. of schist in the southwestern Miami field; not to mention the deep sulphide zone of the Old Dominion vein that extends now nearly 1000 ft. below the ground-water level. How many hundred feet of vein have been eroded above? And how many hundred feet higher was the ground-water at the time when the Gila conglomerate was deposited?

Mr. Tolman explains the fact that many deeply eroded granites are barren, by the assumption that their mineralized outer zone has been destroyed. Is it not much simpler to assume that they never had any? Surface lava flows are very seldom ore-bearing in themselves. Conditions for development of orebodies seem much more favorable in rocks that never reached the surface. Would that not rather point to an accumulation of metallic contents in the central part of an intrusive, where the heat remains active and segregation can work longest? Should all the metallic contents be emptied out at once? Evidence is to the contrary, and, besides, nature does not work in leaps and bounds. Therefore what was possible at the rim facies first should gradually work backward as the cooling progresses and the last contraction breaks and the last healing solution should be near the centre of the mass. In most of the copper deposits of the Morenei type there are two distinct mineralizing processes. A spontaneous one by direct exchange from the liquid or plastic magma into country rock and, as Bergeat has proved at Concepción del Oro, also from the heated country rock back into the magma; and another one, more peaceful and extended, that added silica and metallic sulphides to both the cooling or cooled magma and country rock and healed up their contraction slips and breaks. Is the first one more important, or the second? I would think the latter, as I never saw a district yet that did not prove disappointing where the second was not strongly in evidence, in spite of rich irregular masses in the contact zone. If the second process, the gradual infusion of silica and metallic sulphides from a dying volcanic centre is the cause of our important ore deposits, then why should not the feeding channels, that ought to be more and more trunk channels in depth, become richer and richer in depth? They were affected all the time while metallic sulphides as vapors or solutions passed through them; gradually receding action and partly closed upper channels should cause deposits richer and richer in metal.

To come to a concrete point, why should the pyritic hori-

zon below the chalcocite zone denote the limit of workable ore? Why should not disseminated masses of chalcopyrite and trunk channels of the same mineral exist below the disseminated chalcocite deposits? The source of the copper in those chalcocite zones was supposed to be 'cupriferous' pyrite. The existence of such a thing has been disproved in Butte, for one place. There the fresh pyrite was barren of copper. The copper existed as chalcopyrite, invading the pyrite along joints and cracks. Did that chalcopyrite come from above or below? Did the surface waters collect the copper that did not exist in the pyrite and produce all those secondary copper sulphides? Waldemar Lindgren says that the pyrite below the chalcocite at Morenei is the primary ore, but in his discussion he names, and in his slides he shows, chalcopyrite as the primary sulphide. In Morenei there is pyrite above and pyrite and marcasite below the chalcocite. Are both primary? What became of the primary chalcopyrite? There is plenty of marcasite as well as pyrite in the Old Dominion below the chalcocite. Is marcasite considered a primary mineral? Pyrite occurs in coalbeds, pyrite incrusts fossils, is it primary there? Why is it that Nacozari and Braden, both having only a very slight chalcocite zone, extend deeper than any other disseminated deposit in workable ore, pyrite and chalcopyrite, and show no signs of quitting even at the lowest levels? Is it perhaps because here they mark a primary type?

At Nacozari a lean pyrite zone followed directly under the insignificant chalcocite zone, below was chalcopyrite and pyrite. Primary chalcopyrite might split into chalcocite and pyrite, might it not? Is, therefore, the lean pyrite-zone only the pyritic half of the chalcopyrite that furnished the chalcocite above? Is this pyrite zone thicker according to the thickness of the chalcocite zone above and lacking where it was not developed? Nacozari and Braden point that way.

Will workable chalcopyrite deposits be found below all disseminated chalcocite deposits? Millions and millions hinge on that question. Will somebody show me, convince me, that I am wrong? Till then, I believe in these buried millions.

W. L. TOVOTE.

Globe, Arizona, March 20.

The Mine-Owners' Liability for Accidents

The Editor:

Sir—The 'compensation' principle as applied to recompensing industrial accidents has four separate, irrefragable justifications, any one of which should prove a sufficient foundation to support the Roseberry liability and compensation law. Let us consider them in the order of their importance.

Compensation is based upon society's right to protect itself from those influences which strongly tend to cause persons to become public charges. The 'first law of nature' gives society that right and warrants it in putting forth every effort to prevent pauperism and the crowding of any portion of the people below the poverty line. This unrequited industrial injury does. It ranks third among the four great sources of poverty in the world. Only sickness and unemployment outrank it, while premature death follows immediately after. Therefore, wherever human life is valued, as it is not much in America (as our statistics of accidents in mines and homicides everywhere conclusively prove), drastic laws are made for the safeguarding of industrial life and the employer is compelled to insure against the economic consequences of such accidents as are legally unavoidable. Compensation is, therefore, founded on social justice, and social justice is the highest form of justice known in this world.

Compensation has an economic basis as rock-founded as any principle in the whole science of political economy. A little careful attention to a not at all involved process of reasoning will make this fact clear. Monopoly has ever been regarded as odious, and rightly so, inasmuch as its purpose uniformly is to extort an undue price for the

commodity furnished or service rendered. All countries have laws against monopoly, and the fight against monopoly is one of the fights of the ages, for unless resisted tooth and nail at every point, greed will practise extortion if it can.

All laws against monopoly are based upon the self-evident proposition that the ultimate consumer has a right to have his commodity furnished him at what it is reasonably worth after he shall have compensated, fairly, every person who has rendered a necessary service in the production of such commodity and its distribution to him, from the planting of the seed, or mining of the ore, until the finished product is handed over the counter to him or is delivered at his kitchen door. It is unlawful for any two or more links in this chain of production or distribution to combine for the extortion of more than a fair return for the service rendered. Who can question the correctness of this reasoning? If the foregoing is a true statement of the rights of the consumer, then it follows absolutely that such ultimate consumer has no right to leave any person, in the whole chain of production and distribution, who has rendered a necessary service, uncompensated for the service rendered. The consumer's right not to be made the victim of extortion goes hand in hand with the obligation that rests upon him to pay reasonably for all services necessarily rendered in supplying his needs.

Now, ever since feudalism gave place to free industry, one person, constituting a link in the chain of production and distribution, has been left unpaid. That person is the hurt worker, the victim of industrial accident. In Great Britain, until the law of damages for negligence gave place to the law of compensation without regard to negligence, only seven persons out of each hundred industrially injured ever received damages, and in this country the ratio has been eight to twelve out of the hundred. All the rest have had to bear the burden as best they could, and that it has been a great burden is proved by the fact, to which attention has already been called, that industrial accident ranks third among the great causes of poverty in this world. The economic basis of compensation is unshakable and the problem is to somehow enable (or compel) the ultimate consumer to pay the hurt man for his hurt as certainly as to pay him for his labor. For, after we shall have done all that we can do to prevent accidents, an irreducible minimum of pure accident will remain. The hurt man must be paid. He who has given a hand or foot, an eye or a life to industry, is as worthy of being compensated for his contribution as the man who contributes labor or capital, raw material or business ability.

A stumbling-block in many minds is the requirement of compensation that employers should be called upon to pay for injuries when they themselves were without fault, but if not in the line of fault, they are in the line of causation. Let me illustrate by example: A mine-owner visited the office of the Industrial Accident Board to learn about the law. He went away in high dudgeon, denouncing the law and the legislature that enacted it. He is the owner of a mine that barely pays him a living, but, buoyed by the hope that there are riches (for him) just beyond, he drives his way into the rock as hard as he can. He admitted that some of his men had been killed and their families thrown upon public or private charity, and that many had been injured and sent to the county hospital and cared for without cost to him. This man really felt that conditions had been, all along, just as they should be; that in order that he may live and have a chance to grow rich, he should be free to bore into the earth at whatever cost to life and limb, so long as men were willing to take the chances for 'day's pay,' casting upon society widows and orphans, crippled men and sick, as his own ends might prompt.

But society has said to the railroads, for instance: "Yes, you may run locomotives from ocean to ocean, belching fire at every turn of the wheels and dumping fire-boxes at convenient places, but if any wheat field, house, or barn takes fire from that cause, such railroad must pay for the damage done." In other words, men are to be free to harness great forces for their gain, impound waters, generate electricity

and distribute it, bore into the earth after gold or coal, but if damage is inflicted as a result of this effort, that damage must be made good. Although the employer may not be morally blameworthy, he is in the *line of causation*, and, therefore, must be held responsible for the consequences which flow from the forces which he, for his own profit, sets in motion. Upon this basis rests the whole fabric of laws which require common carriers to be the virtual insurers of passengers and their baggage and of all freight committed to their care for transportation, and Congress is now in process of applying the same principle to compensation for accidents growing out of transportation. The doctrine of 'responsibility through causation' is firmly fixed in the laws of the civilized world.

We now come to the fourth and final justification for compensation. It is founded in that average justice between man and man that approaches ideal justice about as closely as any quality of justice likely to be derived from our clumsy, tardy, and uncertain system of jurisprudence. A workman is hurt. No responsible person is, let us say, blamable for the hurt. The accident just happened, and that is the whole story. The injured employee, under the compensation provisions of the Roseberry law, goes to his employer and, in effect, says: "I am hurt. It is neither your fault nor mine, or perhaps we were both of us somewhat at fault. Now I tell you what I am willing to do. You pay me 65% of what I lose in industrial time while I am getting well; I will stand 35% and I will take for my share all the pain, the disfigurement, the mutilation; this arrangement to last until I get able to go to work again, or if the injury prove permanent, then until I have drawn what I would have been able to earn in three years had I not been hurt, after which I will bear the rest of the loss myself until I sink into my 'six feet of earth'." Isn't that pretty nearly a 'fair shake' as justice is commonly meted out in this world? In most countries compensation goes on as long as the injury lasts, even if for life. The Roseberry law does not, in fact, make whole for all loss sustained. It merely tides the injured person over his period of adversity until he can get on his feet again, and, even doing only this, it constitutes one of the greatest boons to labor that has come to those who toil that others may thrive since industry was made free.

A. J. PILLSBURY.

San Francisco, March 25.

Huanuni Tin-Mining District

Considerable activity has recently been shown in the Huanuni tin-mining district of Bolivia, one of the richest producers of tin in the country, according to the *Pan-American Union*. The large interests of Peny and Duncan have been transferred to another native capitalist, the consideration in the transaction being more than £500,000. The consummation of this sale settles the boundary litigation between the buyer and the sellers and makes the former the largest producer of tin in the Republic. The tendency to concentrate the large tin-mining interests of the country into the hands of Bolivian capitalists, some of whom are at present interested in the building of railways in the Republic, is regarded by the Bolivian press as a favorable step to retain at home the profits produced in the tin-mining industry and the further investment of the profits in new enterprises of the country.

MINERAL exports from Broken Hill, N.S.W., during 1911 constituted a record, the net value being £3,100,109, made up as follows: Silver-lead concentrate, 276,963 tons, value £1,981,439; zinc concentrate, 420,031 tons, value £1,047,020; silver-lead crude, 27,355 tons, value £61,903; silver-lead slime, 11,761 tons, value £9747. The best previous year was 1907, when the total value of the exports was £3,081,031. It must be remembered that the 1911 export figures do not represent the actual total output of the mines along the Broken Hill line of lode, as these returns have not so far reached the Mines Department.

Special Correspondence

TORONTO, CANADA

REAL ESTATE INTEREST INJURES STOCK MARKET.—ONTARIO DEVELOPMENT NOTES.—COBALT INCREASES SHIPMENTS.

The stock market has lately shown a decidedly downward tendency, probably due to the closing down of some of the weaker Porcupine mines, and unfavorable reports from properties for which high expectations were held. The outside public is taking but little interest in mining ventures this season, the great majority of investors being attracted by the prospect of larger profits and fewer risks in real estate. There appears little likelihood of any decided change until tangible results in the shape of dividends from the Porcupine district are in evidence. Reports of the operation of the Dome mill are satisfactory, the recovery of gold being reported as over 98%. The work of the mill is regarded as having demonstrated the fact that Porcupine ores can be effectively handled by the free-milling process. There have been some stoppages for adjustments, but the mill is gradually attaining full capacity and the production is unofficially estimated at \$5000 per day. The plans of the management for the season include 10,000 ft. of underground development. A shaft will be put down to the 500-ft. level and 24 drills will be worked. At the Dome Extension the drift on the 100-ft. level of No. 4 shaft is in pay-ore for 80 ft., the body consisting of banded schist and quartz, which has every appearance of being a large deposit of free-milling ore, though the gold content is unevenly distributed. A cross-cut is being run from the 200-ft. level of No. 1 shaft to tap the orebody at this depth. The Preston East Dome since giving up the Preston property has been working on the East Dome and has cut the vein sought on the 100-ft. level. The showing is regarded as sufficiently good to warrant further development, and the main shaft is being put down to the 200-ft. level. The Vipond has 5000 tons of ore on the dump in readiness for the mill, the construction of which is proceeding steadily. On the main vein there is a continuous shoot of pay-ore for 528 ft. at the 100-ft. level, and 420 ft. of good ore has been developed on the same vein at the 200-ft. level. A 3-ft. quartz vein has been cut in a cross-cut from No. 2 vein at the 100-ft. level. The McIntyre is preparing for the installation of the first unit of 20 stamps with plates and Deister tables for the concentration of the tailing, forming half of its new equipment. The other 20 stamps will be added later, which with the 10 now working will give the mill before the close of the season a total of 50 stamps, with a capacity of between 300 and 350 tons of ore per day. A large new vein was recently intersected on the 200-ft. level of No. 1 shaft. Underground work on the Rea has been discontinued, the veins which promised well on the upper levels having disappeared at 400 ft. The Pearl Lake, which has reached a depth of more than 400 ft. and has had encouraging results from diamond-drilling, has suspended operation until further funds for development can be obtained. The Standard is another company for which the outlook is unfavorable, its treasury being exhausted, and no orebodies of commercial value having been found. The directors have been authorized to raise money by issuing preferred shares or any means they think advisable. The Dome Lake will build a 10-stamp mill, but will not determine the process to be adopted until trial runs have been made with a shipment of its ore. Mr. Robins, manager of the Hollinger, hopes to have the stamp-mill in operation by May 1. Recent development on No. 2 and No. 4 veins continues to show gold content considerably in excess of the estimate of the report. Mowry Bates has resigned as manager of the Hughes and will take a few months rest. He expects to go to Mexico in the summer. Two shafts are being put down on the Miller Middleton and one on the Dixon, both properties belonging to the Timmins syndicate. Development on the 300-ft. level of the Swastika are encouraging. An adit on the ex-

tension of the main vein found in the shaft has been opened up in pay-ore for 100 ft., the vein averaging 2 ft. wide. Another good vein has been tapped by a cross-cut on the same level. The plans for a 10-stamp mill are now complete. There is but little news from the Cobalt district. Production has been well maintained since the opening of the year, with steadily increasing bullion shipments, and a consequent falling off in consignments of ore. The shutting down of the Nova Scotia mill is offset by the increase of 40 stamps at the Northern Customs mill, making 120 stamps in all, and giving it a capacity of 300 tons of ore per day. The Nipissing continues to lead as a producer; its output for the first quarter of the year being 1,179,470 oz., valued at \$916,912. The most encouraging development lately has been in the northern portion of the Nipissing's property, operations in other directions having but indifferent results. On the Meyer vein the Eastern adit has been advanced farther in ore, giving a total length of 363 ft. on the lower level. A fault has now cut off the vein. Development on veins 100 and 80 between the first and second levels is yielding good ore. The Gould Consolidated has cut Nipissing's vein 146 at the 100-ft. level. The McKinley-Darragh has made a good discovery. Driving from a winze sunk 60 ft. below the 150-ft. level a vein from 2 to 3 in. wide has been cut near the Princess line. The Coniagas has declared the regular quarterly dividend of 6%, but has omitted the usual additional 3% bonus. The quarterly statement of the Temiskaming shows a total production of 562,910 oz. at a cost of 16¼c. per ounce. The cash balance on hand was \$484,219, less \$175,000 deferred payments for North Dome.

JOHANNESBURG, TRANSVAAL

RHODESIAN OUTLOOK NOT PROMISING.—RAND HOUSES WITHDRAWING ENGINEERS FROM RHODESIA.

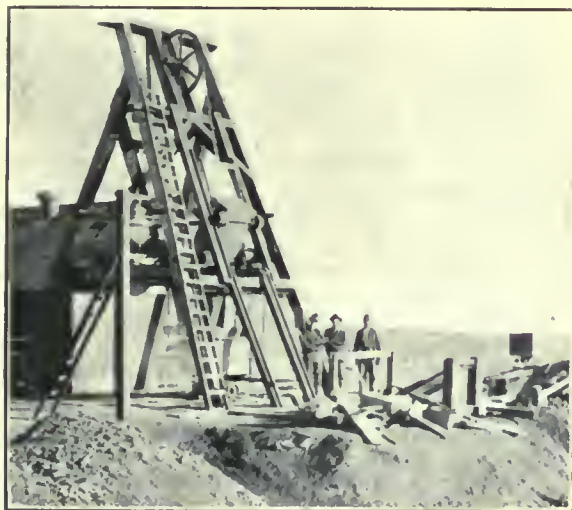

Despite all that may be said regarding mining in Rhodesia the news reaching here more than confirms the unfavorable impressions previously recorded. The present is the season when there ought to be an exodus of engineers from the Rand to Rhodesia to undertake the inspection of promising properties, but instead of this taking place the very reverse is happening. Instead of engineers being despatched to Rhodesia, which in 1909 and 1910 was described as a coming mining country, most of the leading Rand houses are withdrawing their engineers from that country, owing to their inability to make important discoveries, and evidently do not regard the prospects with any degree of confidence or as justifying the incurring of further expense in the present state of Rhodesian mining affairs. Last year's gold output at £2,647,896 did not after all show much improvement on the previous year. The total number of natives employed in mining increased only from 27,824 in 1910 to 38,356 in 1911, and of these but 23,301 were employed on producing mines, the balance of 15,000 being at work on prospects. Then again, no less than 58,328 mining claims were abandoned during 1911, and at the end of the year only 101,472 claims were in existence as compared with 121,472 claims at the end of 1910, which the chairman of the Rhodesian Chamber of Mines claims has strengthened the position because so many worthless claims have disappeared. The importance of the Rhodesian gold-fields may be estimated perhaps by the statement that no less than 6,280,908 tons of profitable ore is developed in the mines, which is exactly the amount considered necessary to have in reserve for the Randfontein Central mill of 600 stamps. There are nevertheless several important gold properties in Rhodesia, and these are not likely to allow the output of gold to dwindle while they have gold reserves assaying over ten million sterling in the mines, but there does not seem much scope for a large increase of output under existing conditions, and little likelihood of the predicted boom taking place at present. There have been too many manipulations accompanied by mine saltings and exaggerated reports of tin discoveries to conduce toward confidence and take the place of solid work. There are not wanting signs that agriculture in Rhodesia is likely in the

immediate future to make more rapid progress than mining. The closing down of the smelters in Kantanga will also have a bad effect on things in general in Northern Rhodesia where so much help was looked for from this direction, while Southern Rhodesia coal mining will suffer through the prospective market for coke failing to materialize.

PIOCHE, NEVADA

HISTORY OF DISTRICT, COMMENCED LAST WEEK, RESUMED.—
WOOLLEY'S RISE AND FALL.

Ernest R. Woolley, when elected president of the Nevada Mines & Smelters Corporation, first attempted to effect a consolidation of the Prince Con. M. Co., the Consolidated Pioche M. Co., and the Nevada holdings of Nevada-Utah. Every mining periodical in the United States announced that this merger had been effected. Without doubt this plan for a time seemed certain of accomplishment. Had it been successful it would have proved the greatest disaster which ever befell Pioche, as such a monopoly would have had the camp at its mercy. Fortunately it failed, and all negotiations to that end were abandoned. In the early part of 1911 the railroad was again washed out, and for four weeks service was suspended. Then traffic was

PRINCE CONSOLIDATED SHAFT.

resumed with semi-weekly service. The Day mine at once resumed shipping at a rate of about 60 tons per day, and the Mendha and other mines sent out an occasional car. Early in June Woolley's promotion activities began to show fruit. About that time there were incorporated in rapid succession the Day-Bristol Con. M. Co., the Pioche Pacific Railroad Co., and the Amalgamated Pioche Mines & Smelters corporation. The Day-Bristol was a merger of the Bristol Con. M. Co.'s property, the Day and Hillside mines of Nevada-Utah, and certain undeveloped claims. The Pioche Pacific railroad took over the 15-mile narrow-gauge railroad formerly belonging to the Nevada-Utah and used to transport the Day ore to the broad-gauge track of the Salt Lake railroad's Pioche branch at Pioche.

The Day-Bristol Con. M. Co.'s property has great possibilities. Most of its mines began producing in 1870 and 1871. While no conclusive figures of total production are obtainable, there can be no question that it has run into the millions of dollars. The crest of the Bristol range is a mile from the terminus of the Pioche Pacific railroad. The first mine on the farther side is the old Hillside, which also was a great producer. A lead smelter, a copper smelter, and a pan-amalgamation mill were all erected to treat ore on that side of the Bristol range. For several years during the eighties the thriving town of Bristol, at the foot of the Bristol range on the farther side, was headquarters for men employed in those mines and mills, and their families. These mines have all been idle for several years, having all been shut down.

The Pioche Pacific railroad was not incorporated until Woolley took it out from the Nevada-Utah holdings and made it a separate institution. Each ton of ore pays a fixed charge for carriage. One of the plans of the Day-Bristol is to construct a tunnel from the Day side to the Bristol side, connecting with all mines on the farther side of the range. Now no ore can be shipped from the Bristol mines without heavy cost for wagon-haul. Such a tunnel will make available hundreds of thousands of tons of low-grade ore which could not bear the wagon charge. It will facilitate the development of all the mines, obviate having heavy hoisting plants, furnish air for the mines, and provide drainage for many years of mining. At present water has not been reached on the Bristol side, but development, it is thought, will soon result in finding water and adding a pumping charge to mining operations. The Amalgamated Pioche was a merger of all properties formerly belonging to the Nevada-Utah company in Nevada (excepting those in the Day-Bristol merger and the Pioche Pacific railroad), the old Ohio-Kentucky, and all other Godbe holdings in Pioche, and of the very valuable Pioche Water Co. In order to effect the Amalgamated Pioche merger, Mr. Woolley secured from the Godbes their Ohio-Kentucky stock, for which he paid them 100,000 shares of Prince stock (taken from the treasury of Nevada-Utah), \$25,000 in cash, and gave a note of the Nevada-Utah for \$125,000, secured by all the stock of the Pioche Pacific railroad, and 300,000 shares of Day-Bristol stock (also taken from the treasury of Nevada-Utah).

BOSTON

SUBURBAN RAILROADS WILL NEED MUCH COPPER.—INDIANA
STOCK RISES.—LAKE SITUATION.

The railroad situation in New England has special bearing on the copper industry. The Governor and the legislators have been canvassing with the New York, New Haven & Hartford officials the matter of leasing the Boston & Maine to the New Haven for a period of 25 years on a 4% basis for outstanding stock of the latter. One of the conditions of this lease is that a tunnel shall be opened and the line electrified from the North Station to the South Station. The plan also includes an ambitious system of railroad electrification. The New Haven will be required to proceed to electrify all lines of both companies within the limits included within the following named points around Boston: Swampscott, Wakefield Junction, Stoneham, Lexington, Winchester, Waltham, Needham Junction, Dedham, Readville, Mattapan, and Braintree. This system of electrification, including the tunnel, must be completed within five years from the date of the lease.

Activity among Lake coppers was recently transferred from Mayflower and Old Colony to Indiana. The first news was received here on Monday, April 15. On the previous Saturday there had not been a transaction in the stock, but Monday's news was followed by transactions of 1500 shares in 15 minutes. The news was that the cross-cut at the 600-ft. level had cut 25 ft. of rich copper ore at a distance of 28 ft. from the shaft. The news stated that large masses of copper weighing 20 to 30 lb. had been found. The news was considered significant by Stephen R. Dow, president of the company, because he claims that it proves the hypothesis on which operations have been conducted—namely, that the Indiana lode is a vertical deposit of rich copper as indicated by the No. 9 drill. The stock at first had an unevenful history on the Curb, but little attention being paid to it. It sold as low as \$5.50. Suddenly, on the strength of drill news, it shot up to \$9.25 in 1908 and had a most sensational run to a high price of \$44.75, meantime being transferred from the Curb to the Exchange. Previous to the find made in the cross-cut of the 600-ft. level the price held around \$15 per share.

It is an interesting situation, even to a layman, that exists among the companies of the Lake district. Mayflower and Old Colony are being closely watched, as well as Indiana, North Lake, South Lake, Algonah, Mass. and

Bohemia, with especial reference to what the drills determine. The deepest and the most scientific drilling ever done in Lake Superior is now under way there. Drilling is not being done altogether to find copper, but to confirm or disprove theories as to the regularity of the formation. Lake and Boston people sometimes seem to be as well satisfied when a drill-core fails to show copper as when it does. These people are studying the situation of the drill-cores in order to work out a theory of ore deposits.

Especial interest attaches to Mayflower and Old Colony because of a tradition handed down that there is what is called the 'Lost Lode' somewhere in their vicinity. This has been indicated by rich spots of ore discovered east of the Calumet & Hecla. Ever since the commercial exploitation of the Lake district there has been a persistent search for this 'Lost Lode.' The Indian, ever figurative, is said to have called it also the 'Moonlight Lode' and the 'Dark Lantern Lode.' Notwithstanding the Lake Copper Co. has done the most important development work at Lake Superior south of Portage lake, and is now on the threshold of permanent shipments, the fact remains that its formation has not yet been determined.

The activity and advance in the price of Tamarack is directly the result of 16c. copper. Tamarack loses money on 12c. copper, but can return dividends of \$5 per share on 16c. copper. Tamarack is doing the deepest copper mining in the world, about a mile deep. The length of its shaft is about the same as that of the Boston subway. In connection with the advance of the price of the stock, the report was made that by a recent re-survey of the property 640 acres was found to belong to the company which heretofore had been credited to other Lake Superior interests. Tamarack has important possibilities in its Osceola lode, providing copper stays at 16c. or better. When copper drops to 14c. Tamarack begins to dwindle as a commercial undertaking. The report of the finding of what appears to be a persistent copper orebody on the 500-ft. level of the Butte Central mine created a stir in Boston.

It has been expected that Charles J. Paine, Jr., president of the St. Mary's Mineral Land Co. and the Winona Copper Co., would succeed Harry F. Fay as president of the Mayflower company. This change was brought about at the first meeting of the newly elected directors on April 17. Other changes were made in accordance with the transfer of control and direction from the Fay regime to St. Mary's. The offices of the company are also to be removed to the Sears building.

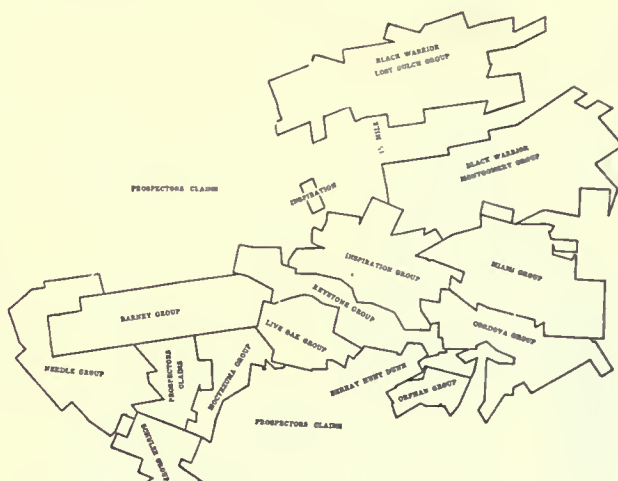

GLOBE, ARIZONA

MIAMI REPORT.—DEVELOPMENT NOTES.—CARMICHAEL ON THE KINNEY BILL.

The March production of the Miami Copper Co. was about 2,900,000 lb. copper, derived from an average of 2800 tons, dry weight, of ore per day. The daily production of concentrate averaged about 125 tons, assaying about 40% copper. Concentrate is shipped to Cananea. There was 5900 ft. of development work done during the month and an average of 800 men employed. The only new construction work going on at present is that of a tower for elevating the tailing, the steelwork being now in course of erection. One of the electric locomotives on the 420-ft. or main haulage level escaped control last week and ran into the cage-compartment of the main shaft, falling to the bottom, a distance of 300 ft. It is stated that aside from the loss of the locomotive the damage was slight and operation has not been affected. F. L. Ransome, of the U. S. Geological Survey, has been staying at the mine during the past week and making an inspection of the underground workings. The work on the Inspiration Consolidated dam across Pinal creek which was delayed by the recent rains and floods, has been resumed. The diverting flume gave way and allowed the excavation and forms to fill with debris, which is now being cleaned out. The test mill at the Inspiration mine is running and the

sinking of No. 2 shaft at the Live Oak mine will be resumed in a few days, the installation of the surface plant being nearly completed. Surveys are under way, but the location of the millsite has not yet been determined.

Churn-drill hole No. 2 of the Southwestern Miami Development Co. has been discontinued at a depth of 1240 ft. and while still in the chalcocite zone. Commercial ore was disclosed in this hole, but how much is not made public. Hole No. 3 is 710 ft. deep and in the chalcocite zone. Holes No. 4, 5, and 6 are 235, 200, and 75 ft. deep, respectively, and have not yet passed through the conglomerate formation. Hole No. 7 will be started in a few days. Churn-drill hole No. 2 on the Barney group is 560 ft. deep and in schist formation. Progress is very slow, the ground being soft and clayey, caving considerably and causing the drill to stick, it being possible to drill only a few feet without driving the casing. Hole No. 3 is 200 ft. deep and is in the conglomerate formation. Churn-drilling continues at the Keystone mine. Hole No. 48 is being drilled at the eastern end of the property near the Inspiration line and is 250 ft. deep, having passed through the granite-porphry into the schist formation.

CLAIM MAP OF MIAMI DISTRICT.

At the Superior & Boston mine the local management states that shipments of ore from the upper levels to the Old Dominion smelter will begin next week. The Gibson mine, nine miles west of Miami, has just shipped to the Old Dominion smelter at Globe another carload of chalcocite ore which is believed to assay about 18% copper. Driving south on the Pasquale vein on the fourth and fifth levels continues. Ore is reported in the face of the drift on the fourth level. Stopping is being done above this level, where it is stated that ore has been exposed for a length of 100 ft. along the vein and of a width from a few inches to three feet. The machinery and equipment for the South Live Oak Development Co., which will explore with churn-drills the Schulze group of 16 claims adjoining the Southwestern Miami on the southwest, is expected within ten days. The road to the site of the first hole has been completed. This hole will be on the western extension of the Augustus claim in the granite-porphry formation. Pipe-lines and water-tanks are being installed. Lessees at the Black Warrior mine, near Miami, are shipping copper silicate ore to the El Paso smelter at the rate of nearly three cars per week. It is reported that the ore assays 9 to 10% copper and is all coming from the 100-ft. level. The company is doing some repair work on the lower levels.

Norman C. Carmichael, general manager for the Arizona Copper Co. at Clifton, is making an inspection of the mines of the Globe-Miami district. Mr. Carmichael states that 200 men are working on the grading for the new smelter at Clifton and that the erection of the steel work should begin in July. He asserts that if the Kinney bill now under consideration by the State legislature at Phoenix should be passed, it would mean a shut-down of the mines in the Clifton-Morenci district. The bill as introduced

provides that it shall be unlawful to employ in mines, mills, smelters, and railroads 'any person who cannot speak and understand the English language,' and charges its enforcement to the State Mine Inspector and his deputies. The workmen of the Clifton-Morenci district are mostly Mexicans, and Mr. Carmichael says that it is impossible to get white men to work and live in the climate and conditions in the district.

GOLDFIELD, NEVADA

DEEP MINING IN THE DISTRICT.—GOLDFIELD DEEP MINES CO. PLANT.

Goldfield district has entered upon a new era, marked by deep mining, in which the Goldfield Consolidated Mines Co. has played the principal rôle. The deepest shaft in the district is still the Grizzly Bear, on the Grizzly Bear claim of the Consolidated. This is down 1300 ft. The next deepest is the Clermont, the main working shaft of the Consolidated properties. This has a depth of 1100 ft. The third deepest shaft on this group is the Laguna, about 800 ft. lateral development is being done from the bottom of the Grizzly Bear and Clermont shafts. The Hazel shaft on the Miss Jessie claim of the Laguna is also down about 800 ft. The three main shafts are all equipped with high-power machinery. The orebodies are stated to persist large and rich as deep work has progressed, and these reports naturally stimulate more operation. A recent estimate places the total yield of the Goldfield Con. properties at over \$48,000,000, including the output of leases. The company has thus far paid \$19,925,757 in dividends, with practically all ore contributing to this produced from above the 1000-ft. point. The Jumbo Extension company claims one of the deepest shafts in the district with its 1030-ft. Polverde shaft. This has tapped promising orebodies. A Gould pump has been installed on the 1030-ft. level and it is likely further deep work will soon be undertaken. The Florence Goldfield company has its main shaft down 1060 ft. and will continue to the 1260-ft. point. Lateral development is planned for the 1000-ft. level, and later work will be done at 1200-ft. depth. Aside from the workings described, little in the way of deep development has thus far been attempted at Goldfield, but within the past few months plans have been made so that the district will be thoroughly explored at depth.

One of the most important of the new plans is fathered by the Goldfield Deep Mines Co., controlling the Merger Mines Co. The main shaft, on the St. Ives claim, has reached a depth of 850 ft. and will be deepened to the 2000-ft. point. This work is expected to exercise a marked influence on the future of the district. The electric hoist is of the 300-hp. intermittent type, capable of operating to a depth of 2500 ft. It is the most powerful hoist in the district. The steel head-frame will be 80 ft. high. The shaft is progressing at a rate of about 150 ft. per month, with four machine-drills used. Ore has been cut at two points since sinking commenced, but no attempt will be made at lateral work until the 1200-ft. level has been opened. The shaft has dimensions of 8 by 17 ft. In addition to opening the Merger Mines estate, the St. Ives shaft will also assist in the exploration of other properties, as it was recently stated arrangements would be made when this shaft attained the 1800-ft. point, by means of which drifts would be extended to open the adjoining Atlanta claims at depth. The latter will also be explored probably by work conducted from the 1300-ft. level of the Goldfield Con. M. Co.'s Grizzly Bear shaft. It is stated that the wealthy interests lately associated with the Atlanta, plan sinking an 1800-ft. shaft on the Black Bear claim. There are two shafts on the Atlanta, the deepest being about 700 feet.

The Blue Bull company plans the sinking of a shaft on the Hat claim, to a depth of at least 1000 ft. This is designed to open the Blue Bull orebodies at depth, also to tap the veins of the Victor claim. The east half of this claim has been leased by the Blue Bull from the C. O. D. Con. M. Co. Shaft-sinking is being done at the Silver

Pick, Vernal, Booth, Goldfield, Belmont, and one or two other properties, and the C. O. D. Con. company is reported to be planning to deepen the 600-ft. shaft of the Gold Bar claim. Deeper mining is planned also by the owners of the Sandstorm-Kendall group.

Besides the sinking of new shafts, considerable development of properties is being done by driving from the old workings of adjoining and more powerful companies. Thus the Combination Fraction is being explored by driving from the old Mohawk workings. Such conditions facilitate

HIGHLAND HOIST, HOMESTAKE MINE.

the opening of small mines at a minimum of development cost, and naturally assists in the exploration of the district. During the past year several small companies have been merged into one strong combination. The various consolidations have united wavering and divergent policies under one vigorous management, as well as obtained funds,

BLACK HILLS, SOUTH DAKOTA

HOMESTAKE OPERATING BY ELECTRICITY.—BLACK HILLS SMELTING CO. PLANS.—OTHER NOTES.

On April 11, the Homestake M. Co. started using power from the Spearfish hydro-electric plant. On that date the first motors were connected in the Amicus 240-stamp mill. All of the stamps which have previously been driven by steam, are now operated by electricity. For running the stamps 25-hp. back-g geared motors are used, one motor for each battery of ten stamps. The power is supplied to these motors at 440 volts, 3 phase, 60 cycles, being stepped down from the transmission line voltage at a sub-station at Lead, adjacent to the Amicus mill. Into this station will also be conveyed the current generated at Englewood, amounting to about 600 hp. The next work for the electricians will be the connecting of the rock-crushers. For each crusher there will be installed a 35-hp. motor, equipped with a heavy fly-wheel. As there are something like a dozen of these motors to be put to work, the task will probably consume some little time. W. E. Walter has arrived to take the superintendency of the Black Hills Smelting Co., at Galena, and as a first step has been making a thorough examination of the mines tributary to the smelter, with a view to learning the probable amount of ore that will be shipped to the plant. He is also investigating pyrite supplies. Nothing will be announced regarding the probable date of blowing in the plant until Mr. Walter reports his findings to the officials of the company. The plant is practically complete and ready to start on short notice. The Deadwood Lead & Zinc Co. recently held its annual meeting, at which the following directors were elected: Aaron Dunn, president; P. M. Bonniwell, vice-president; George S. Jackson, secretary and treasurer; O. N. Brown, and C. S. Ruth. The company is endeavoring to find a suitable treatment for the ore, which has a high percentage of iron pyrite, about 10% zinc, 10% lead, \$3 gold, and 10 oz. silver per ton. At the New Reliance the ten new stamps are now in operation, making in all thirty stamps regularly dropping. W. H. Weigand is superintendent. Charles E. Ellis, who for some time was mill superintendent for the Mogul company, on April 1 accepted a similar position with the Trojan Mining Company.

General Mining News

ALASKA

JUNEAU

The Alaska Treadwell G. M. Co. in March made a production with a 'realizable' value of \$159,782. This was derived from 64,120 tons of ore, which yielded 1146 tons of concentrate valued at \$77,912. The free gold production was valued at \$83,485. The realizable value, however, is given as slightly below the total production of \$161,396. The net profit for the month was \$58,614. The yield per ton was \$2.51. Development work done during the month amounted to 1072 ft., and the stock of broken ore was increased by 42,333 tons.

ARIZONA

GILA COUNTY

The report of the Miami Copper Co. for the year ended December 31 includes the following items:

Sale of 14,970,557 lb. copper at 13.03c.....	\$1,950,669
Other income	33,273

Total income	\$1,983,942
Total expense	1,396,092

Balance	\$ 587,850
Interest on loans and on bonds.....	98,246

Surplus	\$ 528,523
---------------	------------

According to B. B. Gottsberger, general manager for the company, the preparatory stage of the mine has been passed. The first unit of the mill was started March 15, 1911, and production was increased steadily. At the close of the year five units were treating 3500 tons of ore per day.

GREENLEE COUNTY

The Arizona Copper Co. is increasing the capacity of the power-plant equipment for its mines at Clifton by the addition of new machinery, including three 2500-kva. turbo-generators and nine 417-kva. transformers from the General Electric Company.

MOHAVE COUNTY

It is reported that some of the large companies are investigating a copper ore discovery made by Lyon Kay, north of the Keystone mine, near Mineral Park. The Arizona Turquoise mines at Mineral Park will soon have a large force employed. The Ruth is sinking its shaft to the 300-ft. level. The property is in the San Francisco district. Frederiek Lyon, vice-president, and A. P. Anderson, field engineer for the United States S. R. & M. Co., recently inspected the company's holdings in the county.

PINAL COUNTY

The Ray Con. Copper Co. during March produced more than 2,400,000 lb. copper, obtained from 108,700 tons of ore. The profit for the month was about \$157,000. The mining cost was 88c. per ton, 10c. more than last year's average. During the larger part of the month only three units of the mill were operated, but toward the end of the month the fourth unit was used to handle the increased tonnage. The mill treated ore at a rate of 1100 to 1150 tons per unit, the extraction being about 70 per cent.

YAVAPAI COUNTY

Rich silver-gold ore has been found in the Hidden Treasure claim, near Prescott. The property is owned by Charles Bennett.

CALIFORNIA

AMADOR COUNTY

(Special Correspondence.)—Steady progress is being made in unwatering the Plymouth, the water being lowered at the rate of eight feet per day. The shaft has now been recovered to a depth of 800 ft. and in that distance only 14 sets of timbers have had to be re-set. A 500-gal. bailer is being used, with an electric hoist, and work is continuous through three shifts, though shaft repairs interfere some-

what with bailing on the day shift. The mine is to be unwatered to the bottom at 1700 feet.

Jackson, April 24.

(Special Correspondence.)—The shaft at the Keystone has been unwatered and repaired to the 1400-ft. level and a pump placed to drain the 1500-ft. level. It is planned to resume sinking. The property lies near Amador City and is operated by the New Keystone M. Co., for which C. R. Downs is superintendent. The foot-wall ore on the 500-ft. level of the South Amador shows a width of 45 ft. at the point intersected by cross-cuts. The new head-frame at the South Jackson is in course of erection. The Bunker Hill company declared its regular monthly dividend of 7½c. on April 15, marking the seventieth consecutive disbursement. The 1950-ft. shaft of the Lincoln Consolidated has been cleared of water, and from the bottom level a drift is being extended to tap the Wildman-Mahoney orebodies. It is stated the strong vein recently opened on the 2700-ft. level of the Central Eureka has been intersected on the 2800-ft. level. It is believed to be the continuation of the west vein of the South Eureka mine. J. E. Davis is superintendent of the Central Eureka. The Poundstone mine, near Sutter Creek, has been re-named the East Eureka. Machinery at the mine and equipment for the 20-stamp mill are being erected. The shaft of the Plymouth Consolidated has been unwatered to the 700-ft. level and will be cleared to the 1700-ft. level. From this point it is planned to sink the shaft an additional 500 ft. The property is being developed by the California Exploration Co., composed of London capitalists. The Kennedy continues to operate 100 stamps, with a production of about \$80,000 per month. A large percentage of ore is coming from below the 3000-ft. level. Webb Smith is superintendent.

Jackson, April 21.

KERN COUNTY

It is reported that a compromise has been effected adjusting all claims against the Skidoo Mines Co. Charles H. Churchill and Edward Teagle of Randsburg have located several potash claims in the Johannesburg district.

In a preliminary report, Bulletin No. 471-A-5 of the U. S. Geological Survey, on the geology and possible oil resources of the south end of the San Joaquin valley, Robert Anderson states that the stores of petroleum along the foothills of the Temblor range on the southwest side of the valley and in the foothills of the Sierra Nevada near Bakersfield on the northeast side suggest the possibility of finding oil in the foothill belt along the south end of the valley, between the two districts named. He, however, reaches the conclusion that a continuous productive area is by no means to be expected, but that two or more areas situated near the border of the foothills at the south end of the valley offer favorable conditions for the accumulation of oil. Across the level San Joaquin valley from Bakersfield to Buena Vista lake, to the San Emigdio region and to the Tejon region, any oil-bearing rocks probably are too deep to be accessible by present-day drilling.

PLUMAS COUNTY

It is reported that arrangements are being made for building a mill at the Altona mine, in the Greenville district. The property has been bonded to J. W. Dailey.

Grill & McCauly, lessees at the Old Harry claim, ten miles from Quincy, report that 41 tons of ore milled from their last run averaged \$65, says the *Plumas Independent*.

COLORADO

CLEAR CREEK COUNTY

The Anglo-Saxon Mines Co. has started development on its property on Saxon mountain. The mine formerly belonged to the late Henry C. Parker. John Bowen is manager of the property, which is in the Georgetown district. The Mineral Chief mill will be started May 1 by Stephens Bros. & Old, lessees on the Linn Con. M. Co. property. The mill during the summer will be run on the dump material.

GILPIN COUNTY

Ore assaying as high as 25 oz. gold and 6000 oz. silver

per ton, according to newspaper reports, was found in the Coaley mine. The streak from which the ore was taken is 2 to 8 in. wide. The Castle Rock shaft will be sunk an additional 200 ft. Joseph Tuckfield, superintendent of the property, has completed the new foundation for the hoist. Richard Fraser and James Flynn recently shipped from the War Danee property six tons of ore that brought them \$500 per ton, and six tons valued at \$111 per ton.

OURAY COUNTY

It is rumored that Robert J. Lucas may resume operation of his Mineral Farm mine. Development will be started soon at the Molly mine, Red Mountain district, after a shut-down of twenty years. A. E. Ackerson recently bought the property from Blanchard & Buskirk.

TELLER COUNTY (CRIPPLE CREEK)

Kenneth McKenzie, who bought the title to the St. Thomas G. M. Co., has proposed to the stockholders a re-organization of the company under the name of the Peoria G. M. Co. The property, which McKenzie acquired at a tax sale, is under lease to the 101 M. Co., for which Charles Crowder is general manager. John B. Neville, president and general manager for the Free Coinage G. M. Co., has bought the Delmonico claim. The Portland estate has withdrawn the Colorado City claim from the property to be leased.

IDAHO

IDAHO COUNTY

The Revenue M. & M. Co., recently organized in Spokane by Harlow H. Dean and associates, has taken over the old

Bassett; secretary-treasurer, Walker Guthrie; directors, E. F. Cartier Van Dissel, and Thomas Olsen.

SHOSHONE COUNTY

The Bunker Hill & Sullivan M. & C. Co.'s mill, costing \$375,000, placed in commission at Kellogg, a few days ago, is said to be the largest silver-lead concentrating plant in the world. Its capacity is 35,000 tons per month. The mill is operated by electricity, 750 hp. being required. Construction work was started in 1907, the first unit with ore-house and conveyor being completed in December 1910. The mill is equipped with ore-bins of 3000 tons. Concrete and native timber were used in the buildings.

Sinking will be resumed at the Bullion, of which J. H. Taylor is manager. Ore from the property is said to assay over 12% copper, and to have fluxing properties which make it valuable to smelters.

At the Marsh mine, near Burke, it is reported that a 4-ft. vein of high-grade galena, assaying as high as \$80 per ton, was cut at a depth of 456 ft. below the No. 2 adit. The company has just signed a five-year contract with the International S. & R. Co. to treat its ore. In a drift west, 12 ft. from the point in the cross-cut where the ore was discovered, the vein has widened to 6½ ft. Of this, 30 in. is high-grade shipping ore.

The Hecla M. Co.'s April dividend of \$20,000, at the rate of 2 cents per share, places the disbursements at \$80,000 for the first four months of 1912, or \$2,430,000 to date.

MONTANA

MUSSELSHELL COUNTY

C. W. Scott and C. C. Shultze are planning to develop the former's coal property near Roundup. The coal of the district is bituminous. The land is crossed by the Billings & Northern railroad.

SILVERBOW COUNTY

(Special Correspondence.)—The Davis-Daly company expects to be in a position to increase shipments next month from the Colorado mine. The orebody on the 1700-ft. level is improving, some of the ore showing 10% copper. Some ore is being mined on the 1400-ft. level. Some time ago the shaft of the Raven mine was unwatered and now prospecting is in progress on the lower levels, but up to the present with little success. It was contended that with the water removed a rich orebody would be found on the 1300-ft. level, but none of real value has yet been discovered. The Butte-Ballaklava company has commenced shipping ore from the 1400-ft. level, which it is claimed is in ground which is not in dispute with the Anaconda company. For the present a carload every other day will be sent to the East Butte smelter, and C. W. Newton, the superintendent, hopes to be in a position in a short time to increase the shipments to a carload per day. The ore being shipped is taken from stopes. It is stated that as the stoping proceeds the ore is showing improvement.

Butte, April 22.

The North Butte M. Co., says the annual report recently issued, in the year ended December 31 produced 24,816,669 lb. copper, 1,134,300 oz. silver, and 1281 oz. gold. The ore reserve on January 1 amounted to 710,920 tons, with an average assay value of 41½% copper and 4.25 oz. silver per ton. The profit of the company for the past four years has been tabulated as follows by the *Boston Commercial*.

Year.	Gross receipts.	Net profits.	Per share.
Dec. 31.			
1908	\$4,701,829	\$1,863,282	\$4.66
1909	4,083,284	1,036,305	2.59
1910	3,790,991	560,888	1.40
1911	3,752,160	641,858	1.56

Lateral development was confined chiefly to the Croesus and Snowball veins. Development for the year amounted to 17,700 ft. Decrease in the ore reserve, as noted in the quarterly reports, is attributed by James Houtson, president of the company, to the fact that the Edith May and Jessie veins above the 2400-ft. level had been largely explored, and to the sinking of the Speculator shaft, which precluded much work below the 2200-ft. level. Since the

California mine, near the junction of the American and Red rivers, in the Elk City district. The mine was worked as placer ground in the early days, but was later located as a quartz claim by W. C. Smith, who ran a 600-ft. adit on the main lode, which opened an orebody of promise. G. J. Calvert will be superintendent. The officers of the company are: president, H. H. Dean; vice-president, S. S.

last report was issued, the company has purchased an additional three-tenths interest in the Charlie and Protection claims.

NEVADA

CLARK COUNTY

Paul Barlock is planning to prospect his Missoula group of three claims near Searchlight. The property has a 35-ft. shaft equipped with a 9-hp. Fairbanks-Morse gasoline hoist. Work is to be resumed soon at the Searchlight-Parallel property. Walter R. Fales, of Los Angeles, will be in charge of the mine.

ESMERALDA COUNTY

(Special Correspondence.)—A reorganization has been announced of the Lone Star M. Co. under the name of the Lone Star Con. M. Co. It is reported that the financial condition of the new company is good, and that extensive development work will be done. The company's property is close to Consolidated Mines and Jumbo Extension. The Lone Star Consolidated company is capitalized at \$2,500,000, and stock in it will be exchanged for stock in the old company on payment of 2c. per share. It is believed this provision will make unnecessary any assessment within a year. The stock must be exchanged within three months.

Goldfield, April 20.

The 7 by 18-ft. shaft of the Goldfield Merger Mines Co. was 900 ft. deep on April 18, and the sinking is progressing at a rate of about 140 ft. per month, say Goldfield advices. The ground penetrated so far is firm. No lateral development will be started until a depth of 1400 ft. has been reached. Three shifts are employed.

LANDER COUNTY

(Special Correspondence.)—The Maricopa Mines Co. has resumed operation in the True Blue adit and workings in New York canyon. The vein in the stope is said to be five feet wide, with the ore mined running 20 oz. silver per ton. The second vein is smaller, but is said to be richer. It is planned to place the mill in commission early in June. The Salt Lake interests recently taking over the Austin Central properties on a long-term lease is driving an adit along the dike paralleling the Jack Pot veins. Renewed activity is reported by the Bullion Mountain company in the Bullion district. A shaft has been started and an adit is under way to prospect the porphyry dike. The Georgia Nevada M. Co. reports that at an inclined depth of 150 ft. a small vein of high-grade silver and gold ore has been cut. At another point a 5-ft. vein is being opened. This is said to assay about \$39, principally silver. W. D. Scott is president.

Austin, April 20.

LINCOLN COUNTY

The Prince Con. M. Co. has issued a statement for the quarter ended March 31 which shows the company in that time received \$103,760.

LYON COUNTY

The Mason Valley smelter recently established a new record, according to newspaper reports, by treating 710 tons of ore in 24 hours.

Press reports state that much interest has been aroused by the discovery of copper sulphide ore on the 200-ft. level of the Copper King, owned by the Queen Regent Merger Mines Co., near Schurz.

NYE COUNTY

(Special Correspondence.)—The Big Four company has taken charge of the Big Four mine, and arrangements are practically completed for sinking the main shaft to the 500-ft. level. Between the 300 and 400-ft. levels the vein shows a width of about 60 ft. L. K. Koontz, president, states that thousands of tons of milling ore is available for treatment in the upper workings, and that a modern milling plant will be built immediately. The Poak-Steen-Cicala lease has completed its run at the Priest mill, and from the final clean-up 455 oz. of bullion valued at \$6850 was produced. During about 20 months of operation this lease produced over \$300,000. It is understood the members of the leasing company plan to take over other hold-

ings in the district. The 10-stamp Associated mill is crushing the first shipment of 1000 tons of ore from the Steffner lease, on Manhattan Con. property. The contract with the mill calls for an initial treatment of 2000 tons from Steffner's lease. The next handled will be 1000 tons from the White Caps mine. The Dexter-Union is arranging for work on company account. Work will be carried on from the Rose-Nash shaft on the Union No. 4 claim. A good vein of milling ore has been exposed by lessees. S. C. Durkee has been chosen superintendent. The Swanson lease on the Earl reports opening two strong shoots on the 250-ft. level. The orebodies run about four feet wide and average around \$12 per ton. The vein recently cut in the Mushet-Wittenberg lease on Manhattan Con. land is said to be four feet wide. It was found at the 125-ft. level and is said to assay over \$150 per ton. The lease adjoins the Steffner workings.

Manhattan, April 20.

In the Manhattan district, ore from the Mineral Hill Consolidated adit assayed as high as \$128 per ton. Previous assays from the same orebody were \$29 and \$33, and the management hopes to cut a rich ore-shoot. In the Kendall-Douglas lease of the Silver Pick claim of the Manhattan Consolidated, a 7-ft. vein assaying about \$75 was cut recently, according to press reports.

The Tonopah Belmont Development Co.'s report for the year ended February 29 shows that the net earnings of the company amounted to \$1,802,081, as against \$1,502,381 for the preceding year. A résumé of the report will be given in next week's issue of the *Mining and Scientific Press*.

The production of the Tonopah district for the quarter ended March 31 is summarized as follows by the *Tonopah Miner*:

Company.	Jan.	Feb.	Mar.	Total.
Tonopah Mining	14,943	14,326	14,706	43,975
Belmont	10,363	9,813	8,609	28,785
Montana	4,724	4,092	4,748	13,564
Tonopah Extension	3,775	3,822	4,618	12,215
West End Con.	2,798	3,288	3,170	9,256
MacNamara	317	1,595	1,700	3,612
Midway	180	180
Totals	37,100	36,936	37,551	111,587

Estimated gross value, \$2,890,810. The falling off in the production of the Belmont mine is due solely to the cessation of shipments to smelters during the retimbering of the main shaft. The West End shipments for March include 113 tons of high-grade ore sent to the smelter.

STOREY COUNTY

In connection with the usual development, the Union Con. mine produced 191 tons of ore averaging about \$20 and shipped 389 tons of second-class ore to the Kinkead mill. The Mexican mill, running 66% of the week, crushed 402 tons of ore which averaged \$24.28, with an apparent extraction of 92%. Repairs were made to the Chilean mill, tube-mills, and agitators. Twelve bars of bullion were shipped to the Selby S. & L. Co. The customary development work was done on the other Comstock properties. The Nevada Deep Mines Co. has ordered a 70-ton mill from the Union Iron Works. It is to be running in about three months. The property is at Como.

WHITE PINE COUNTY

(Special Correspondence.)—The Giroux shaft has been unwatered to the bottom, 1445 ft., and has been thoroughly cleaned. The water at a depth of 1400 ft. flows wholly toward the Alpha, and pumping has been started to keep the water from flooding the 1200-ft. level, and preventing prospecting above that level. It is not probable that work will be resumed there until ore shipped from the Morris shaft will pay for it. It is a question whether the Zack shaft of the Ely Consolidated has much ore. The discovery of a small body of sulphide ore, however, has been widely advertised.

Ely, April 20.

Reports from Ely state that geologists for the Tonopah M. Co. have completed a preliminary examination of the Argus and Monitor mines and several claims at Taylor. The properties are under option to the Tonopah company.

The Smokey Development Co., owning 175 acres near Lane, is planning to start driving an adit within two weeks, according to H. P. Eastwood, one of the organizers of the company. The property is between the Federal Ely and Chainman Consolidated properties.

NEW MEXICO

SOCORRO COUNTY

(Special Correspondence.)—The Ernestine M. Co., produced bullion in the last 10 days of March amounting to 8850 oz., concentrate for the period was 12,000 lb. The total output for the month was 22,640 oz. bullion, and 161½ tons concentrate, from an ore treatment of 3200 tons. The tonnage last week was 660. The Deadwood Mines plant is in operation, the upper workings furnish the mill with ore. A fair tonnage of custom ore is handled.

The Treasure M. & R. Co. is delivering 60 tons per day to the mill on Whitewater creek. Work on the Johnson mine, a patented property, has disclosed gold and silver ore, and the extent of the orebody is being determined. The Mogollon Gold & Copper Co., has let a new working lease on the Little Charlie mine to Los Angeles capitalists. It is probable the other holdings of this company will be handled by the same people. Lessees on the Pacific mine are taking out a good tonnage of mill ore, largely from development, amounting to a total of 40 ft. of work during the week.

Mogollon, April 12.

OKLAHOMA

OTTAWA COUNTY

(Special Correspondence.)—The Baxter-Quapaw district, idle for many months save for occasional spasmodic operations, is showing signs of activity, and a big centrifugal pump has been erected at the Omaha-Petersburg mine. The ground is so saturated with water, as a result of the continuous rains and snows of the late winter and early spring, that drainage is a serious problem. Many mines have suffered heavily from surface floods, but the chief source of annoyance has been the increased underground seepage. A last effort has been made to work the Hackett mine, which is equipped with one of the most costly plants in the district. It was built at a cost of \$80,000 and operated first with one type of jig and then another. New York people have taken over the Hackett and have drained the ground. The best mill recovery was barely in excess of 2%, but the present operators believe they can handle this low-grade ore at a profit at the present high price of zinc. Employment is now given to 13,000 men throughout the district, embracing mines in the adjoining corners of the three states of Missouri, Kansas, and Oklahoma. Eight hundred companies are operating. The output of zincblende is close to 6000 tons per week, calamine 500 tons, and lead 1000. Only American labor is employed, all efforts to introduce foreign workmen having failed. Many of the workmen are now members of the union, and efforts at unionizing the entire district are meeting with more or less success.

Quapaw, April 19.

UTAH

JUAB COUNTY

(Special Correspondence.)—Utah mining men are greatly disturbed over a recent decision of the general land office in the case of the East Tintic Con. M. Co. which upsets all previous practice as to securing patent for mining claims. The decision is interpreted as meaning that hereafter the mineral claimant must actually develop a valuable mine before he can secure patent, no matter how favorable the mineral indications are. The decision says:

"It is evident from the record that the deposits alleged to have been exposed on these claims are regarded by the applicant as possessing practically no economic value, but that, on the other hand, title to the claims is sought essen-

tially on account of the possible value for certain unexposed deposits supposed to exist at considerable depth below the surface, and having no connection, so far as shown, with any deposits appearing on the surface.

"The exposure, however, of substantially worthless deposits on the surface of a claim; the finding of mere surface indications of mineral within its limits; the discovery of valuable mineral deposits outside the claim, or deductions from established geological facts relating to it; one or all of which matters may reasonably give rise to a hope or belief, however strong it may be, that a valuable mineral deposit exists within the claim, will neither suffice as a discovery thereon, nor be entitled to be accepted as the equivalent thereof.

"To constitute a valid discovery upon a claim for which patent is sought there must be actually and physically exposed within the limits thereof a vein or lode of mineral-bearing rock in place, possessing in and of itself a present or prospective value for mining purposes; and before patent can properly be issued or entry allowed thereon, that fact must be shown in the manner above stated."

Eureka, April 22.

The new machinery for the Iron Blossom No. 3 shaft has been delivered at Tintic. According to reports from the property, the Dragon mine, which is operated through the Iron Blossom company's shaft, is producing ore which assays 2 oz. gold, 20 to 40 oz. silver, and 2% copper per ton. According to an estimate by Walter Fitch, manager for the company, the Chief Consolidated in March produced about \$56,000. Erick Levin has taken a lease on part of the dump at the Eureka Hill mine, other lessees being William Clark and Elijah Bowden.

SALT LAKE COUNTY

(Special Correspondence.)—D. C. Jackling, general manager for the Utah Copper Co., is authority for the statement that the company will increase its tonnage steadily until the maximum is reached. The ninth unit of the Arthur mill is now in commission and the milling capacity of the company is now 18,000 tons per day.

Salt Lake City, April 22.

Strikers caused a temporary shut-down of underground work at Bingham, and the mills are supplied with ore from only the steam-shovels. The supply thus cut off furnished about 15% of the total tonnage. The machine men demanded a raise from \$3 to \$3.50 per day, according to a report. The Utah Copper Co. invited them to send a spokesman to discuss the matter, but no one appeared. The strikers resumed work in a few days.

SUMMIT COUNTY

(Special Correspondence.)—The Daly-Judge has begun marketing its zinc product, which was being held for a time pending the negotiation of a favorable contract. A deal was recently made with the United States Smelting, Refining & Mining Co., and now the tonnage of the Daly-Judge is being rapidly increased. The zinc product is going to the Midvale plant of the United States company, where separation is made by the Huff electrostatic process.

Park City, April 23.

Stockholders in the Diamond-Nimrod company have received a letter stating that on March 26 the holders of \$48,915 notes against the company and of 101,337 shares of the stock had sold their interest to Harry Joseph of Salt Lake City for \$75,000, with the stipulation that he should pay 10c. per share for the rest of the capital stock. The provision states that the certificates for such shares, properly endorsed, must be deposited with the Chicago Title & Trust Co., of Chicago, on or before June 25, and that Joseph is to deposit with the same company \$13,867.80 as security. It is rumored that the Daly West company is interested in the deal. H. G. McMillan, manager for the Daly West company, recently stated that the mill will be in operation about May 1. The present shut-down, due to the failure of Silver lake to thaw, is the longest in years. No quarterly report will be issued for the first three months of 1912.

UTAH COUNTY

The Opohongo M. Co. has declared a dividend of 1c. per share, payable April 30 to stockholders of record April 25. The dividend will require \$8950, and will bring the total amount disbursed to stockholders to \$26,850.

WASHINGTON

SPOKANE COUNTY

Legislative needs of the Pacific coast and intermountain states will be discussed at a Western welfare conference, called by the Spokane Mining Men's club to meet in a city, to be agreed upon, before the national political conventions. L. K. Armstrong, president of the organization, has forwarded invitations to the governors of California, Oregon, Nevada, New Mexico, Arizona, Utah, Washington, Idaho, Wyoming, Colorado, Montana, North Dakota, and South Dakota and representative citizens of the thirteen states to select a place of meeting and fix the dates.

CANADA

ONTARIO

Special Correspondence.)—Construction work on the Elk Lake branch of the Temiskaming & Northern Ontario railway has begun and it is expected that the line will be completed by November 1. The prospect of railway facilities has revived interest in the Elk Lake and Gowganda mining industry, and some formerly promising properties are being re-opened and new prospects developed. A good many mining men are going in from Porcupine. A recent shipment of 15 tons of high-grade ore from the Mann property, Gowganda, has realized over \$38,000, or a profit of \$32,000 after deducting mining and marketing expenses.

Toronto, April 17.

The fourth gold brick from the McIntyre mill was shipped April 17. It weighed 180 oz. and was valued at \$3000.

In 1911 the La Rose Consolidated Mines Co. produced 3,691,797 oz. silver, at a total cost of 19.2c. per ounce. Shipments for the year amounted to 4,092,709 oz. silver. The net profit was \$1,269,086. This was 64% of the production.

YUKON

The Canadian Klondike M. Co. and the Treadgold interests in the Klondike basin have been merged, according to an announcement by Charles Boyle, Jr., resident manager for the Canadian Klondike company. The telegram from J. W. Boyle, president of the company, telling of the consolidation, also stated that a third dredge has been ordered, of the same size as the dredge *Canadian*, now being operated. Last month it was announced that the second, a duplicate of the present dredge, said to be the largest in the world, had been ordered from the Marion company. The consolidated properties will be under one management, with J. W. Boyle in charge, and under the present name of the company. Among the Treadgold properties absorbed are the Granville Power Co. and the Bonanza Basin Company.

MEXICO

SONORA

The action of the United States Government in not allowing explosives to cross into Mexico is causing several of the small companies to cease operations. It is understood that there are quite a number of companies which at present have but a small amount of explosives on hand, and if the embargo is not raised in the near future they, too, will be compelled to cease operations until such time that conditions allow. The Cananea Con. Copper Co. has a sufficient supply on hand to last them eight or nine weeks, and it is thought by that time conditions will be such that powder will be allowed to enter Mexico. It is understood that the matter has been taken up with the United States Government, so that arrangements can be made to import powder, the Federal Government to see to its delivery. Without powder thousands of men will be thrown out of employment in Sonora, and it is to be hoped that this condition will not present itself.—*Mexican Herald*.

Among the Copper Mines

The EAGLE & BLUE BELL shaft, Tintic district, is expected to cut the main orebody on the 1400-ft. level by July 1.

NEVADA-UTAH stockholders in Boston who followed Lawson held a meeting recently and endorsed the plans of the shareholders' protective committee.

The BUTTE & SUPERIOR COPPER Co. has decided to issue 30,000 shares at \$27.50 per share. The entire issue has been underwritten by a Boston banking house.

The SHANNON COPPER Co. has found it necessary to blow in an additional small furnace, as its large furnace has been overtaxed. It is believed that April will be a record-breaking month for the company from the point of view of costs and earnings.

The NORTH BUTTE M. Co. last year made a net profit of \$1.56 per share, as against \$1.40 per share in 1910, \$2.59 in 1909, and \$4.66 per share in 1908. Gross receipts last year amounted to \$3,752,160, as against \$3,790,991 in 1910. The total net profit was \$641,858, as against \$560,888 in the preceding year.

L. VOGELSTEIN & Co. give the following figures of German consumption of foreign copper for the months of January-February, 1912:

	Tons.
Imports of copper.....	33,787
Exports of copper.....	1,713
Consumption of copper.....	32,074

as compared with consumption in 1911 of 28,138 tons. Of this quantity 29,293 tons came from the United States.

The CALUMET & ARIZONA COMPANY has made one of the most important ore finds in its history. The ore was found in a cross-out 522 ft. from the Briggs shaft on the thirteenth level. The ore is sulphide and assays made on several days averaged 35%. They have averaged by days, 31.8, 40, 22, 24, 27, and 41%. This find follows several recent finds on the twelfth and thirteenth levels of the Briggs shaft averaging 7 to 10% copper and \$3 per ton in gold, which are holding out. It only takes 1250 tons of 40% ore to produce 100,000 lb. copper.—*News Letter*.

UTAH CONSOLIDATED stock having declined almost \$8 per share on the announcement that its developed ore reserves decreased 105,565 tons in 1911, a comparison of the more important features of its operations last year, as shown in its annual report, with those of the North Butte M. Co. will be interesting.

	Utah Con. North Butte.

—*Boston Commercial*.

Personal

Professional men are invited to send news of their engagements and travels. Such news is interesting to friends.

E. GYBBON SPILSBURY is in Texas.

EDMUND B. KIRBY is in New York.

D. W. BRUNTON was in New York recently.

M. R. HYDLIFF has been visiting San Francisco.

FREDERICK LYON was in San Francisco Thursday.

F. M. SIMONDS is in Cuba on professional business.

J. PARKE CHANNING was at the Miami mine recently.

H. S. DENNY was in New York on his way to London.

H. C. CALLAHAN left for Panama on the *Sonoma*, Thursday.

J. V. N. DORR is spending two weeks in southern California.

JOHN WEIR and H. R. ROOD were among those lost on the *Titanic*.

F. O. JASMER has gone to Santiago Papasquiaro for six months.

HENRY H. ARMSTEAD, of Guanajuato, is in New York for a month.

A. CHESTER BEATTY sailed from New York for London on April 23.

T. A. RICKARD sailed from New York for England on the *Cedric*, April 18.

HOWARD D. SMITH has returned from a professional trip to the California oilfields.

STUART H. INGRAM, from La Cumbre, was in San Francisco, and has gone to Nevada.

CHARLES JANIN is returning from France and will go to Alaska to examine placer ground.

RENSSELAER H. TOLL is examining mines in the San Juan district and will be at Ouray until May 15.

T. H. JENKS has returned to Denver, after a four-months professional trip to Mexico, Arizona, and New Mexico.

WILLIS LAWRENCE is general superintendent for the Chosen Mining Co. at Ko Sung mines, Yeng Byen, Korea.

CHARLES W. GUTTZERT has resigned from the general management of the Titan Steel Casting Co. of Newark, New Jersey.

ROBERT H. RICHARDS is in Denver on professional business and will visit Rolla, Missouri, and Houghton, Michigan, on his way East.

J. H. LORING, of Cobalt, Ontario, who was a passenger on the *Titanic*, was not, as reported, a relative of W. J. LORING, none of whose family were on the steamer.

J. B. TYRRELL will be the leader of the Ontario government expedition to locate the ten-mile strip at the mouth of the Nelson river and the five-mile strip along Hudson's Bay, which Ontario has been granted by the Dominion.

Obituary

HORACE J. STEVENS, best known because of his 'Copper Handbook,' died from heart failure at Houghton, Michigan, on April 22. Mr. Stevens was born at Conewango, New York, in 1866 and received his education in the schools and academies of the vicinity as well as during service as a country school teacher. Removing to Michigan in 1883 he served in a variety of capacities at the Beaufort mine, eventually becoming a reporter on the *Marquette Mining Journal*. After five years of this experience he started the *Peninsular News Bureau*, which prospered under his management and led to the publication in 1901 of the first volume of 'The Copper Handbook,' which quickly established a place for itself, and is the work for which he was known to mining engineers, though in Michigan he was one of the best known newspaper men of the upper peninsula.

Concentrates

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

TERNE-PLATE is an inferior variety of tin-plate, made from tin alloyed with a large percentage of lead. It is chiefly used for roofing purposes and for lining packing cases for ocean shipment.

DIAMONDS, according to O. A. Derby, may have resulted from the segregation of a portion of the C of CO₂, a gas which is always present in kimberlite, the rock with which diamonds are associated.

LIME can be burned with almost any fuel. The use of wood is common throughout the West, while in the Eastern United States coal is ordinarily employed. At Allentown, Pennsylvania, coke is employed for this purpose.

MACHINE-DRILL air-hose is wrapped with flat wire to protect the hose from damage while in use, but this protection has its limits. Few, if any, brands of hose will stand having machines thrown down on them, or withstand blasting.

NOILS have nothing to do with nails, being the short pieces and knots taken from the long staple of wool in the process of combing. They are used for felting purposes, or made into inferior yarns which are put into cloth to increase its thickness.

OREBODIES often change in character in depth. Some of the mines at Bingham, Utah, were originally worked for gold, later for copper, and are now yielding lead. At Leadville gold was first sought for, then the district became famous for its silver-lead production and now is an important producer of zinc.

NUMBER of men employed in the world's mines and quarries exceeded 6,000,000 for the year 1909, according to a recent report of the British chief inspector of mines. The total number was probably nearer 8,000,000; since the English figures include for the United States only the coal miners and some of the metal miners. A few countries such as Bolivia with its tin mines, Brazil with its gem fields, China with its coal, iron, and tin mines, Turkey, and Persia are unrepresented in the statistics.

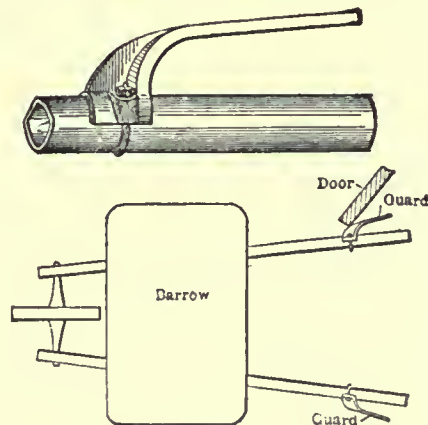

SMOKE is absolutely necessary in steel metallurgy. Any operation that removes the carbon will produce poor steel. If a smokeless flame is used, all the carbon is burned out and the surface of the steel is made rotten. English magistrates realize that smoke is essential to the manufacture of good steel and exempt metallurgical furnaces, but the question of mixed stacks is continually coming up to the annoyance of manufacturers. So far as health is concerned, the most mischief is caused by household smoke, yet it is usually ignored by the smoke inspectors. Strange as it may seem, some medical men have recently taken to recommending the smoky parts of Sheffield, England, for sufferers from asthma.

CO-OWNERS can be eliminated from a claim when they refuse to share the expense of development, but in 'advertising out' a co-owner, the demand can only be made for the co-owner's share of the work at the rate of \$100 per claim. If more than \$100 per claim was spent, the co-owner's refusal to contribute on a basis of more than \$100 cannot be used, under the statute, to work a forfeiture of his rights in the claim. It appears that if a certain co-owner or co-owners have the work performed, any forfeited ownerships will inure to them solely, instead of being also apportioned among the other co-owners who may subsequently offer to pay their share toward the forfeited portions. If the demand is made by personal notice in writ-

ing, the delinquent has ninety days within which to respond and pay his portion. If the demand is made by publication for ninety days in the newspaper published nearest the claim, as should always be done if the delinquent cannot be readily found or reached, the delinquent has ninety days from expiration of period of publication within which to respond.

MONZONITE is a kind of eruptive rock that displays considerable mineralogical variation, but is usually considered a variety of augite-syenite. Brügger has applied the name to a transitional group of rocks between the granite-syenite series and the diorites. The true monzonites have both alkali feldspar and lime-soda feldspar in approximately equal amounts, or at least both richly. Numerous varieties, such as quartz-monzonite, are distinguished. The rock monzonite should not be confused with the mineral monazite, which is a phosphate of cerium, lanthanum, and didymium, but contains a number of other alkaline-earth elements, of which thorium is the most important, and from which it derives its value for the manufacture of mantles for incandescent gas burners.

DOORWAYS are sometimes narrow, with the result that the knuckles and back of a barrow wheeler's hands are forced against the door post. With a swinging door or one drawn shut by a weight, the blow against the exposed hand

comes with greater impact. This can be obviated by a knuckle guard, as shown in the accompanying figure taken from the *Journal of Industrial Safety*, that serves to receive the blow and protect the hand.

WHITE PIGMENTS which have zinc for a base, either in whole or in part, are four in number; namely, zinc oxide, leaded zinc oxide, zinc-lead oxide, and lithopone. All of these may be, and in the United States the first three usually are, made directly from ore. Zinc oxide is the most important of these pigments. In European practice the oxide is made from spelter, though in France zinc oxide is made from ore in the electrothermic furnace invented by Côte and Pierron. In the United States the oxide is generally made from ore, but in 1909, of the total production, 3255 tons was made from spelter. The production of zinc oxide made a large gain in 1909, being 68,974 short tons, as compared with 57,237 tons in 1908, an increase of over 20%, but not quite equaling the production of 1906 and 1907. The imports of zinc oxide in 1909 were 3327 short tons, and the exports for the same period were 14,846 tons. Leaded zinc oxide and zinc-lead oxide are produced from ore, both in some cases at the same plant, the zinc-lead containing somewhat the larger percentage of lead. The combined production of these two pigments in 1909 was 7655 short tons, as compared with 8430 tons in 1908. Lithopone is an intimate mixture by chemical precipitation of zinc sulphide and barium sulphate. It may be manufactured from spelter or zinc oxide, but in the United States it is now generally made from zinc skimmings, ashes, and scrap. The zinc content of the various zinc pigments made in the United States in 1909 from ore, both domestic and foreign, was 54,139 short tons, as compared with 48,004 tons zinc content in 1908 and 56,391 tons in 1907.

EDITORIAL

ALASKA trails are opening unusually early this season. It is announced that river boats to Dawson from White Horse are to start May 10.

DEFEAT of the rebels at Tepic helps the Mexican situation a trifle. A few good battles would clear the air amazingly. The trouble is that the great majority of the Mexicans, while peaceable, are not like the Hoosier who would have peace "if he had to fight for it."

GROUND is being cleared at Observatory inlet in British Columbia for the power-house and smelter to be built this year by the Granby Consolidated Mining, Smelting & Power Company, Ltd., which by a fortunate purchase on the coast bids fair to renew its youth.

CLOSING of the Mammoth smelter at Kennett, California, is threatened by the farmers. The suit is of especial interest, since it raises the question of how far the bag-house solves smelter-fume troubles. If the farmers are able to show substantial damage under existing conditions, it means that metallurgists must frankly face the problem of neutralizing SO₂ fumes as well as giving protection against SO₂ and dust.

ACCORDING to the quarterly report of the Nevada Consolidated Copper Company, the production in January, February, and March amounted to 6,309,228, 4,888,790, and 6,380,432 pounds, respectively, making a total of 17,578,450 pounds of copper in three months. The ore milled amounted to 728,592 tons, averaging 1.85 per cent copper. These figures may be compared with interest with those for 1911, as given by Mr. Pope Yeatman.

TONOPAH is enjoying well deserved prosperity. The report of the Tonopah Belmont Mining & Development Company, summarized on another page, is a cheerful record of good work done and good prospects for the future. Reports of the Tonopah Mining Company and others of the companies operating in the district are equally satisfactory. Improvements in technology and the rise in the price of silver have helped the Tonopah companies, but back of these is the fact that the district is one of great and rich orebodies and, despite the unusual amount of faulting to which these have been subjected, the capable men in charge have learned how to find the ore economically.

SELLING of roofing plate by weight instead of by area is an improvement in trade practice which is to be commended. Under the former system unscrupulous sellers found it easy to substitute sheets of a lighter gauge than specified and escape detection, but where the weight is specified such a subterfuge is impossible. Changes in the metal industry are likely to result from the introduction of 'lohnmannizing,' a process whereby lead is deposited on sheets and tubes of iron after a manner similar to sherardizing with zinc. The process is too new for all its excellences and defects to be known as yet, but it seems more likely to develop new uses for the new product rather than to restrict the market for tinplate.

MECHANICAL handling of ore at smelters is important and economical, not only because of the saving in labor, but because it permits accurate sampling and mixing—and the first essential to good furnace work is a regular feed. At Cananea mechanical devices have been introduced to an unusual extent, despite the fact that Mexico is one of the so-called cheap labor countries, and the plant has amply justified its designers and builders. To the original plant built by the Robins Conveying Belt Company for handling ore, has recently been added an extensive one, built by the Stephens-Adamson Manufacturing Company, for handling the concentrate from the Miami mill, now smelted at Cananea. We print this week an account of the whole system by Mr. M. J. Elsing, with views of the new part of the plant, furnished by Mr. Colby N. Avery. While the climate at Cananea permits out-of-door handling of material and thereby cheapens construction, the essential features of the system are widely applicable.

A FAVORABLE report has been made by the House Committee on Mines and Mining on the amended Raker bill for the establishment of a mining experiment station at Auburn, California. The bill has been changed so as to avoid the conflict with private ore-testing plants possible under the bill as first drawn. It is now proposed that the station shall be under charge of the Bureau of Mines and shall be empowered to do only those things which it is proposed the Bureau shall hereafter do. We believe it would be better to let the Bureau work where and when needed and not to tie up money in a local station with the inevitable demand for other local stations and the development of a pork-cutting contest—which indeed has already begun and received approval in the favorable report of the House Committee on the Taylor bill proposing a similar station at Silverton, Colorado. We are in favor of the proposed work, but the most effective argument for centring it at Auburn seems to be that Mr. Raker is the only Democratic congressman from California, and it would be better to postpone expansion of the investigations than to have them become the football of partisan politics.

GEOLGY in its relation to ore deposits has received much attention in recent years, and since Emmons mapped the faults at Leadville, the value of the study of the structural geology of a district has been generally recognized. On another page Mr. C. A. Stewart draws from practice, instructive examples of the value of other phases of geological study. In a day when 'secondary enrichment' has become the stock word of the mining promoter, it is worth while to emphasize the limitations as well as the possibilities of the application of geological knowledge, and we join Mr. Stewart in urging that this is a field where a little knowledge may lead one far astray. Mining companies too often make the mistake of employing poorly trained men at first. When the deposit shows only as a prospect, while plans are being formulated that must control development of the whole property, then is the time when the most expert of assistance is needed. When the mine is developed and the vagaries of the particular deposit have been learned, a less able man can keep things going. Spend money freely as well as carefully at first, that you may save money from useless development. In a faulted region careful study by a trained geologist should prevent many mistakes in underground work, and neither drills nor drifts should be employed till the surface has been mapped; it affords the one complete ground plan that will ever be open to observation. In too many cases little or no use is made of this opportunity.

Prospectors and Buyers

Many claim-holders wonder why they are unable to interest buyers in their properties, and resent the fact that their proposals are rejected by engineers who have never been on the property, just as young authors stick a few pages of manuscript together to catch the editor who rejects without reading. As a matter of fact, engineers are amply justified in refusing to incur for themselves or clients the expense of an examination when the prospectus furnished by the prospector himself shows that the man who writes it does not know what he is talking about. We quote below a few paragraphs from a letter sent by an American prospector to an English financial house, whose name he had seen in a paper. He doubtless wonders why their consulting engineer refused to make a trip to the property despite his 'reasonable' terms. As to what he says: "I have no fancy price on it; if I retain an interest I will take \$150,000, and will let you pay me out of the ores if I have a little to go on till sale." The district is one in which there are no profitable mines and in which repeated attempts to find ore have failed. The owner has merely undeveloped claims and in suggesting an 'interest' and \$150,000 he shows himself entirely unfamiliar with mine valuation. He describes several veins. What he writes about two of them is sufficient to show that he knows as little about sampling as about valuing mines.

"No. 1," he says, "is gold and copper, being 300 to 600 ft. wide. Its course is N.E. to S.W. as all the other leads are; its surface is much leached and its values precipitated downward like most all large copper bodies are. Some quartz runs as high as 2½ oz. in gold and 84% in copper at, or near, the surface, still the erosion is so great it can be shoveled like ashes. It has all the colors of the rainbow—it cuts into about the middle of a large porphyry and lime mountain—the yellow porphyry is about a mile wide on the side of the mountain and pans gold—the top is capped with lime and great iron columns protrude through the porphyry and lime—at the base in the vein there is over 100 ft. solid red oxide of copper in width—the vein seems to be about 600 ft. wide. My lowest tunnel will cut this mountain about 500 ft. deep and follow the vein all the way and have pay quartz from the start; also have 6000 horse water power at the mouth of the tunnel, and this lead is continuous through the entire range and comes out on the opposite side in the vicinity of great coal fields and where water is abundant, making it a water and railroad proposition as well as mineral, having less than 2% grade to the tunnel, said tunnel being about 30 miles from the valley, and a railroad could follow the river all the way. There has been some grading for a railway line in that direction. Timber is abundant of all sizes, red and white spruce predominating. There are two tunnels each 40 ft. in length." Continuing, he says of No. 6 that it "is my last find, in September last—it is also a remarkable demonstration of nature, being to the best of my knowledge about 500 ft. wide where it outcrops about half way up the mountain which it cuts about the middle. At the base is iron quartz of immense bodies, and at the top of this porphyry and lime mountain are high needles like protruding out through the formation, several hundred feet high. Some of the quartz runs as high as \$486 per ton, but much of it will be lower grade I expect. No work done except surface work—a tunnel at the base will cut 2000 to 3000 ft. deep on it."

This prospectus was referred to a busy and capable engineer, who is hardly likely to use his clients' money in searching for a lead 600 ft. wide and containing "100 ft. solid red oxide of copper." In other words, the writer

uses terms so carelessly as to make it clear that his observations are valueless. To sell a claim, a prospector must first have something of real value, and, second, present it in such terms that the buyer can see that his observations and statements are accurate.

Chinese Finance

It is natural that public opinion should regard the work of governmental reform in China as having been completed with the announcement of the establishment of a republic and the election of a president, but the real labor of the institution of a representative form of government has only just begun. With nations as with men, the problem of securing funds to meet obligations and finance undertakings is an urgent one; one, indeed, that is of critical importance to the infant Chinese republic. Much of China's trouble has grown out of a bad monetary, banking, and revenue system, which persists in spite of its defects because it is so difficult to change. Of the monetary system we shall say nothing; much space would be required to do justice to its faults, and banking may be similarly passed over, concentrating our attention on the revenue and liabilities of China. The revenue has heretofore been derived from a land tax, tribute, customs receipts, both native and foreign, salt gabelle, likin or transit tax, and miscellaneous taxes. Of this the foreign customs yield over one-third of the total, the land tax one-fourth, and the salt gabelle and the likin about one-eighth each. The expenditures are chiefly for payments on foreign loans and indemnities, one-third of the total; grants for provincial administration, one-fourth; army, navy, and fortifications, one-fifth; miscellaneous items serving to make up a total which usually exceeded the total revenue by nearly one-third, thus making necessary further foreign loans. The foreign debt of China in 1906 amounted to over \$675,000,000, over one-half of which represented indemnities, while only \$60,000,000 was in the form of railway loans. Since that time other railway loans have been incurred, as well as the Manchurian loan of \$50,000,000, so that the new six-power loan of \$300,000,000 will put the foreign debt of China well above the \$1,000,000,000 mark. The interest charge upon this will approximate \$45,000,000 (the loans bear differing rates of interest) and, following the former custom, will presumably be secured by the receipt of the foreign customs. These amount to less than \$25,000,000 and represent over one-third of the national revenue. Since the army and navy and the administration of the provinces have heretofore absorbed about \$36,000,000, and miscellaneous expenditures have required half as much more, it would seem as though China requires a business manager more urgently than a president.

The annual revenue of the United States is eight-tenths of its total debt; of Russia, more than one-fourth, and of Great Britain, one-fifth. China's present revenue amounts to only one-twentieth of its foreign debt, the bonds of the other countries named being largely held by their own citizens. How much the revenue of China can be increased is a difficult problem. The dues now imposed on foreign trade amount to 5 per cent *ad valorem*, and this can be increased somewhat, as provided in the treaties existing between China and the principal commercial nations, but not to any great extent, as the interested powers can scarcely be expected to look with favor upon taxing their trade to provide funds to meet the interest upon their loans. The likin, or transit tax, should be abolished, rather than increased; it is and always has been a clog upon the wheels of trade, offering infinite opportunity for oppression of the small merchant and for speculation by the tax gatherers. The salt gabelle is an economic ana-

chronism; many countries have imposed such a tax in the primitive stages of their development, but have abolished them in the course of national progress. The people of China are, on the average, on almost the lowest level of poverty, and in addition large areas are now in the grip of famine, and it is scarcely possible that land and other internal taxes can be increased without plunging them deeper into the mire from which the national leaders are hoping to draw them. It is clear, then, that the nation's financial salvation must come from the increased receipts from the Government-owned enterprises, such as railways, telegraphs, and mines, supplemented by increased taxation upon foreign trade and the increased national prosperity which is expected to result from the development of the national resources. The courageous inception of the new form of government in China must be looked upon as the biggest politico-financial undertaking in all history. What its outcome will be it is impossible to prophesy. To successfully develop a new form of government under such a financial load is surely a super-task, calling for super-men. Has China super-men?

Denzaburo Fujita

Osaka advices report the death, March 30 at his home, of Baron Denzaburo Fujita, head of the Fujitagumi, one of the largest private companies in Japan. To mining men he is known especially for his connection with the Kosaka mine. This great property, as has been true of so many copper mines, was long worked in a small way for silver only, the oxidized ore being treated by the Augustin process. Below was a large body of copper ore containing 12 to 30 per cent barite and peculiarly difficult to treat. One of the younger engineers connected with the company, Mr. K. Takeda, became convinced that this ore could be smelted, and with the approval of Baron Fujita, came to America and studied smelting methods. On his return a pyrite smelting plant was erected and put in blast in 1897, and from that date progress at the mine has been rapid. A 60-foot furnace was built, and at the time it was the largest in the world. Open-ent methods of mining followed, and for some years the Kosaka was the largest copper mine in the Far East. Baron Fujita was born of poor parents under the old regime. He founded his house in 1869, and his remarkable success testifies not only to the opportunities of the last generation in Japan, but to the open-mindedness of the men who have led. It required courage of a high order to back Mr. Takeda in building furnaces to treat an ore that had baffled many experimenters. Another side of his character was shown when he gave an option on the Kosaka mine, his best property, in order to raise money for investment in government bonds at the time of the Japanese-Russian war. The bonds paid relatively small interest and the mine paid well, but the country needed the money. The mine, which was priced at \$8,000,000, was examined by Messrs. N. B. Knox and John B. Farish and a deal was nearly concluded. Differences of opinion developed with the option holder as to his commission and the sale was not made. Fortunately for the owner, copper rose to such a price that he was able to hold the mine and still buy the bonds, and for his services in that connection the Emperor conferred the Second Class Order of the Rising Sun. On the occasion of the recent visit of American Mining Engineers to Osaka, Baron Fujita tendered them an elaborate luncheon and extended many individual courtesies. One of the first to rally to the defense of the Emperor in his contest with the shogun, he became one of the leaders of New Japan, and his death will be felt as a loss abroad as well as at home.

Handling Furnace Charges at Cananea

By MORRIS JESUP ELSING

The methods of handling furnace charges at the smelting plant of the Greene-Cananea Copper Co., Cananea, Sonora, Mexico, involves many unique features. Under the management of Arthur S. Dwight, with the assistance of E. H. Messiter, consulting engineer for the Robins Conveying Belt Co., there are a series of belt conveyors and mechanical devices designed and constructed for mixing the blast-furnace charge and delivering it to the furnace. Several parts of the original construction have been replaced because of difficulty found in operating, and the installation is now working with great success. A diagrammatic 'flow-sheet' shown on the opposite page illustrates the following description, and shows details of

the bins through a steel chute which is provided with an are gate. In order to assist the steady feeding of this wet material, an attendant is stationed at the chute with a compressed-air harring device. This device consists of a piece of 1-in. pipe about 6 ft. long to which is attached a short piece of tapered pipe with a $\frac{1}{4}$ -in. opening in the end. A compressed-air hose and valve is attached to the other end of the 6-ft. length. When compressed air is turned on, this device becomes a very sufficient means of harring down material that otherwise 'hangs up.' The different classes of ores, such as heavy sulphide ore, limestone ore, and the silicious ores are kept in separate bins as well as the by-products that are smelted in the blast-furnace.

FIG. 1. GENERAL VIEW OF SMELTING PLANT, GREENE-CANANEA COPPER CO.

capacity. The 'flow-sheet' of the sampling works is also included.

In outline the plant as it stands today consists of a series of eleven receiving bins, constructed of wood, for ore and secondaries, and eight steel bins for concentrate and picked ore. These bins are filled by trains from the mines and concentrator, after each car has been weighed on a Fairbanks scale. The bins are equipped with automatic feeding devices that feed into a hopper and to a belt conveyor, which transports the material to the sampling works, where it is automatically sampled.

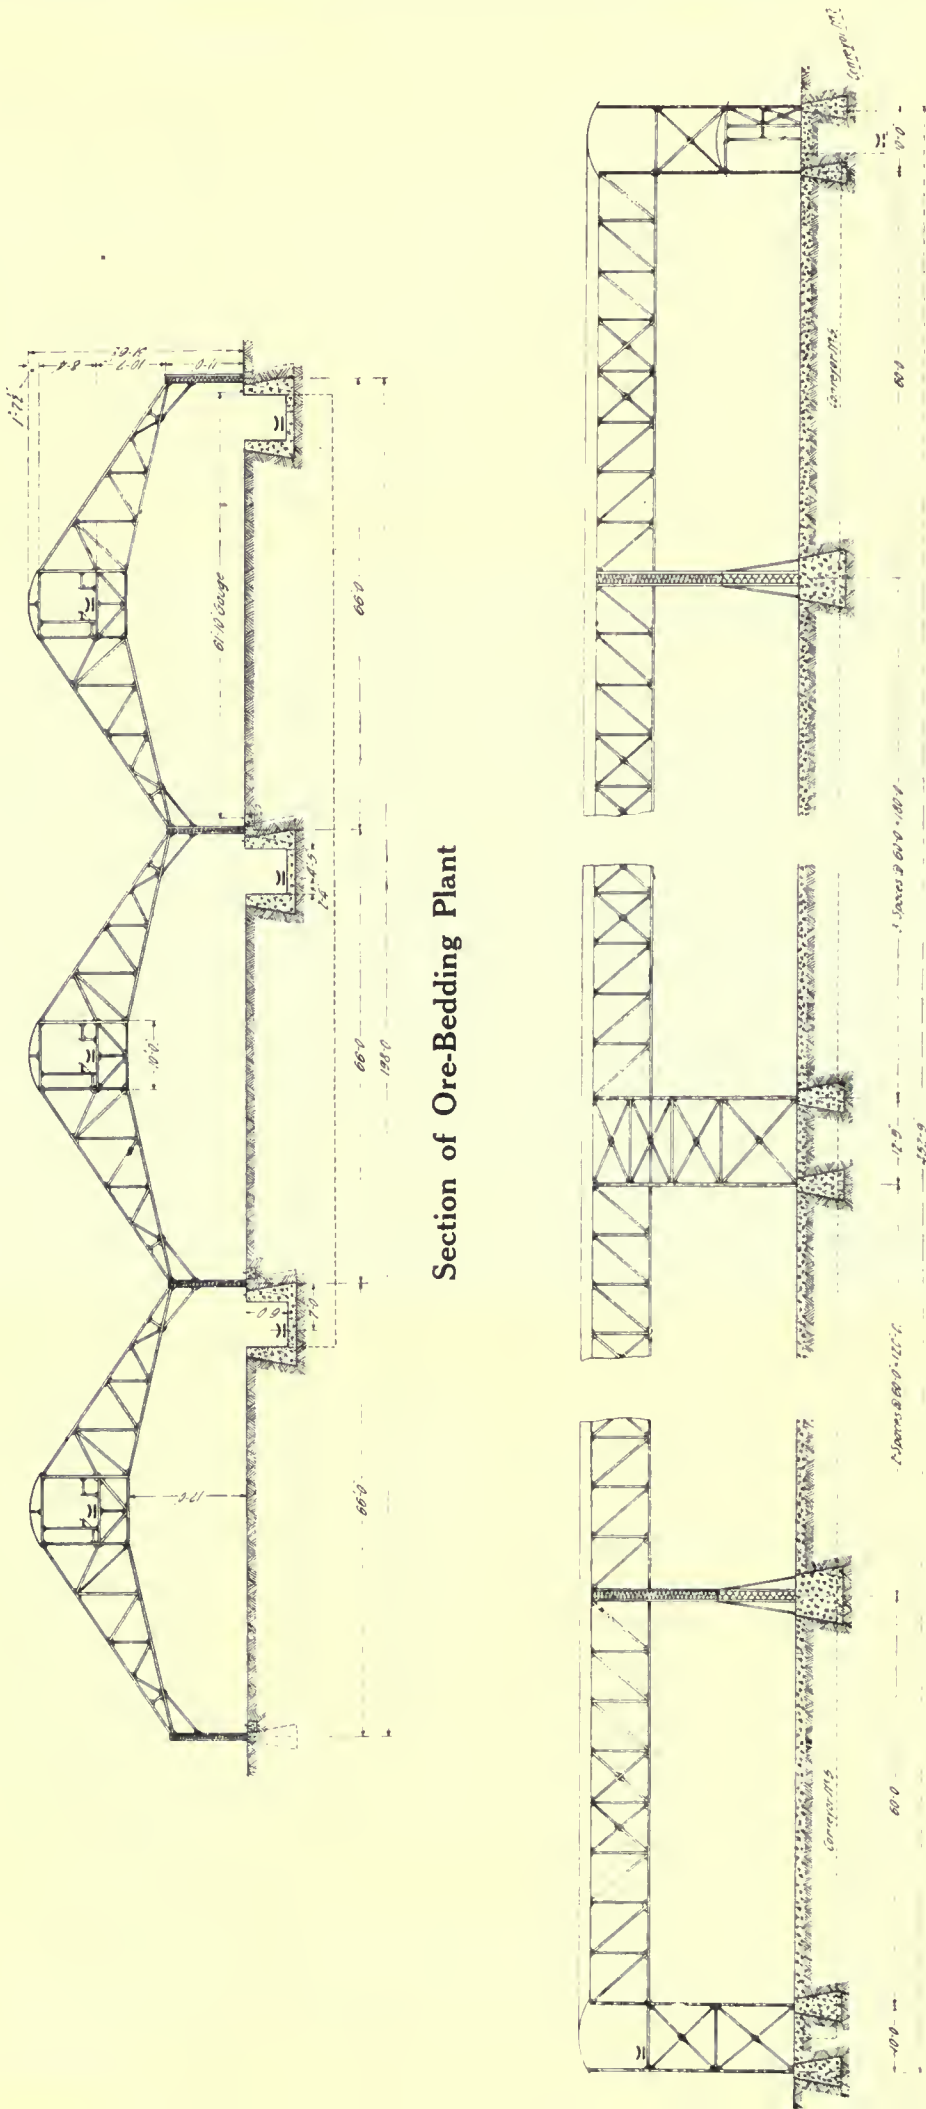

The feeding device attached to the wooden bins consists of a steel table suspended by four rods at the bottom of the bins. This steel table is given a reciprocating movement by a connecting-rod attached to an eccentric placed at the back of the bins. This eccentric is attached to a shafting, which runs the entire length of the wooden bins. Each of these bins has four of these feeding devices. The ore feeds into a movable steel hopper, which breaks its fall upon the belt. The picked ore from the steel bins is fed upon the belt by a shaker feed-car, which is a hopper mounted on a carriage astride of the conveyor. This hopper has a table below its discharge opening, which is given a reciprocating motion feeding the material on the belt at the desired rate, which is controlled by certain adjustments.

The concentrate is fed upon the belt from the bottom of

From the sampling works the material is conveyed to one of three parallel belts, which are supported on steel bridges about 20 ft. above a concrete floor (see Fig. 3). By means of Robins Conveying Belt Co.'s automatic trippers, a long narrow pile or bed is built up in successive layers. The tripper is a carriage astride of the conveyor belt, through which the belt passes. The direction of travel is determined by certain fixed brakes and traction wheels, which are reversed on reaching the end of the conveyor. In this way a continuous stream of ore is spread on the floor below the traveling tripper. The receiving bins containing known ton-nages of material, whose approximate analysis is already known, are in turn emptied on the bed. From the sample taken as the ore passes through the mill, the exact amount of each constituent of the charge is determined, and as the bed nears completion, such materials are added to make it the self-fluxing mixture that is desired.

RECLAMATION

The reclamation of this bed of self-fluxing material is accomplished by a device known as the reclaimers, which was especially designed for this work. It consists of a traveling steel bridge or framework, which spans the entire width of the bed, and is mounted on car wheels and rides on rails. Under the forward side of the bridge is suspended a scraper conveyor, operating on a nearly horizontal steel

Section of Ore-Bedding Plant

Fig. 3

bottom plate. The flights are inclined to the axis of the conveyor, and are provided with plough-shaped extensions, which draw on to the bottom plate all material within reach, and carry it along to a conveyor paralleling the bed, and placed in a trench a little below the elevation of the floor of the bed (see Fig. 4). A triangular harrow covering the entire cross-section of the bed, and given an inclination of approximately the angle of repose of the material, is mounted on the front of the machine. The harrow is given a reciprocating motion cross-wise to a pile, which dislodges the material in a continuous manner from all parts of the face of the bed, and causes it to roll down to the conveyor below, by which it is carried away as described.

An electric motor operates the harrow and scraper conveyor while a smaller motor advances the machine into the

two-fold and may be divided into mechanical cost and metallurgical cost. The mechanical cost has been reduced by the elimination, so far as possible, of manual labor, and its replacement by the use of the mechanical devices described. The metallurgical reduction is due to the uniformity in the chemical composition and the physical character of the charge, and to advance information on these subjects.

It is evident that a given amount of ore will not often make an even number of layers on the bed, and, therefore, there will be an overlapping of layers. When the bed is completed it contains about 9000 tons or about 40,000 lb. per linear foot. With each overlap, roughly 50 lb. per foot has been added, and the result is that any particular foot may receive 1 800 more or less of a certain flux or ore than some other foot. This overlap will not constantly occur

FIG. 4. MECHANICAL PLANT FOR HANDLING CONCENTRATE (Stephens-Adamson construction).

pile at any desired rate, or runs it back to the end of the bed, where it is transferred to the next bed by a transfer car. The thoroughly mixed charge then passes to the other belt conveyors, being elevated and finally discharged directly into narrow steel storage bins of 75 tons' capacity above each blast-furnace. These bins feed steel pockets containing about one ton each, which are partly emptied into the furnace, and partly on the feeding floor by the simple operation of a chute and deflecting gate. The coke is brought to the furnace in wheelbarrows. The whole system of conveying and reclaiming is controlled by a series of signals so that each operator of any part is notified when to commence operations or of any stopping or over-load, thus unifying the whole system.

ADVANTAGES

Among the advantages due to this method of mixing and delivering the furnace charge the reduction of the cost of smelting is the most important. This reduction of cost is

at any one place in the bed, but it will be compensating. It will apply to all of the different materials added to the bed and the final outcome will be only infinitesimal variation in the analysis of any transverse section of the bed. The thorough mixing of the charge by the reclaiming machine is self-evident. Its advance into the bed is approximately an inch per minute, so that only a small quantity is being taken from every part of the cross-section. The inclination of the harrow being adjustable, makes it possible to set it at an angle so that material being agitated by it will roll down from every part of the pile and be combined on the bottom plate.

Due to the elimination of the variation in the composition of the charge, it is possible to operate the furnace with a lower factor of safety. In nearly every other method of charging there is a constant variation in conditions; that is, at one time the slag being produced is more acid, and at another more basic than desired. Due to this constant change, it becomes necessary not only to add fluxes to counteract

these differences and restore equilibrium, but to use an excessive amount of coke, and the outcome is that costs increase. With this careful mixture of charge, however, the analyses of the slags obtained can be predicted with extreme accuracy. With a given mixture they will show little variation from day to day, and the costs are brought down to a minimum. Other conditions being equal, accretions can in part be traced more or less directly to variation in the composition of the charge.

To summarize, with an exact knowledge of the composition and physical character of the furnace charge it has been possible to increase the speed of smelting, to reduce excessive accretions in the furnace, to reduce the amount of costly fluxes, coke, and air-blast required, and it has been possible also to increase the percentage of fine in the charge.

ROASTER BEDDING PLANT

A system somewhat similar to that in use for the blast-furnace charge has recently been installed by the Stephens-Adamson Manufacturing Co. for handling the concentrate that is roasted, and then sent to the reverberatory furnaces. The concentrate is emptied from the standard railroad cars that come from the mill into especially designed bins. From the bins it is transported by belt conveyors to a bridge below which a bed is formed by a traveling tripper. The reclamation of the bedded concentrate is accomplished by means of a transverse belt conveyor, mounted upon a movable carriage. The roaster charge is then shoveled upon this transverse belt, which discharges into a longitudinal belt, and is conveyed to the roaster bins where it is fed to the roasters as required.

Geology in the Examination of Prospects

By C. A. STEWART

That accurate knowledge of the geology of an ore deposit is essential to proper mining and development, is generally recognized. Many of the large mining companies now employ a force of geologists to keep careful records of the underground geology, and smaller companies, that do not require the services of specialists the year around, are accustomed to have geological examinations of their properties made from time to time as new developments show the need. In most cases, however, this work is done only by companies that have producing mines. It is the purpose of this article to point out ways in which geological work can be of value even when the property is little more than a prospect. As a matter of fact, examination of prospects is in large part geology. Engineering training is necessary to determine whether or not the ore can be mined, and its metals extracted at a profit, for such a determination requires a knowledge of mining and metallurgical methods and their costs. But the possibilities of the extent of the orebody, its probable changes in shape and mineral character in depth, are matters of geology and matters involving detailed study and not the rule-of-thumb methods often used.

CLASSIFICATION OF THE DEPOSIT

It is often entirely possible, even from surface showings, to refer an ore deposit to one of several classes based upon origin, and from this classification to tell much of its probable shape and relationship to the country rocks. It would require a whole treatise on economic geology to discuss all known classes of ore deposits, but for purposes of illustration four types may be considered that are most often met in the West, namely, fissure veins, contact-metamorphic deposits, irregular replacements not contact-metamorphic, and impregnations.

Fissure Veins.—Deposits of this type are widespread and easily recognized, and there is no need of defining them or of pointing out their usual characteristics in depth. Because true fissure veins are so common many orebodies are put in this class that do not belong there, and I have seen

many instances of adits and cross-cuts driven to intersect the 'vein' in depth which never met the ore—not because it was 'faulted out', but because it was not a vein. In true vein deposits it is important to distinguish between those which are the result of filling open fissures and those which are the result of replacement of the wall-rocks along narrow cracks which themselves would not be wide enough to furnish workable orebodies. The changes which may be expected when a vein of the first type (open-fissure filling) passes from one rock formation to another are those dependent upon the kind of resistance the different rocks offer to forces of fissuring. Homogeneous rocks, like the igneous rocks and massively-bedded sediments, are likely to give wide, well defined fissures; shaly and schistose rocks, on the other hand, often cause the fissure to split up into small cracks so that an orebody that is a sharply defined vein in a granite or a sandstone may change to a mass of small stringers on passing into a shale, schist, or slate, and the reverse. Veins of the second class (replacement veins) generally vary in width with the solubility of the wall-rock. Such veins may be mere stringers in granite or quartzite and widen out into rich bonanzas where they cut more soluble rocks, such as limestone. Igneous rocks with an abundance of the dark silicates (hornblende, augite, and biotite) are more favorable to replacement than the light-colored granites. The two processes of vein formation may have been at work in different parts of the same vein, while in other cases no replacement may be shown, and the vein may be a true fissure filling throughout, and its value depend entirely upon the size of the original crevice. For this reason, no man, no matter how expert a geologist, can absolutely predict the action of veins with depth. A geologist can never be a substitute for the prospecting shaft, but he can ascertain the nature of the underlying rocks from the geology of the surrounding country, point out the probabilities, and thus prevent the building of too elaborate 'air castles' or the premature abandoning of a good possibility. Moreover, when prospecting has once revealed a change in vein character, he can see its significance and make important predictions from it.

Contact-Metamorphic Deposits.—Ore deposits of this class are found at the contact of igneous and sedimentary rocks, and have as gangue minerals garnet, epidote, pyroxene, wollastonite, and rarer contact-metamorphic silicates. Their position and characteristic gangue minerals make them easily recognizable, but because their outcrops are sometimes linear in extent, they may be mistaken for veins, and serious mistakes in exploration thus result. Contact-metamorphic ores are most often irregular in shape—bunches, pockets, and lens-shaped masses from a few feet to many hundreds of feet in dimensions. They usually hold close to the contact, and follow its numerous windings. Limestone is the most favorable country rock, although ores in other rocks are known. A careful study of deposits of this class makes necessary a subdivision into two classes, which act differently.¹ Thorough exploration of these ores must be based upon a geological map that will show the igneous-sedimentary contact, and the position of the several sediments. To make such a map is often a difficult matter, for excessive metamorphism in the district may produce rocks that are hard to classify. I have in mind a district in which the contact character of the ore was recognized, and an attempt made to direct prospecting along the contact. The engineers were misled, however, into taking a puzzling metamorphic rock for a porphyry, and drove hundreds of feet along it until a man better versed in geology pointed out their mistake.

Irregular Replacements Not Contact-Metamorphic.—Under this head are included orebodies not apparently related to fissures or to igneous contacts, and formed by replacement of the wall rocks. The deposits of Leadville are among the most famous of this class. The ores may show all the irregularities of the contact-metamorphic ores and present greater difficulties to exploration because there is no contact line to serve as a guide. Their shape and

¹C. A. Stewart, *Eng. and Min. Jour.*, Sept. 10, 1910.

location is, however, usually dependent upon some geologic structure that a careful study will make clear. A detailed study of these factors has recently been published,² so a brief reference to the more important is sufficient. Replacement bodies are often found along lines of fracture that because of insignificant size and lack of ore pass unnoticed. When such a condition is recognized, it is possible to locate these lines of fracture, and to conduct underground exploration along them with good results. At other times the replacement occurs along the contact of the ore-bearing formation and an impervious rock, which has dammed up the ore solutions and thus caused them to deposit their minerals. In general, limestones are the rocks most often containing replacement deposits, but certain beds, either because of greater porosity or greater purity, may be more favorable than others of the same formation. The recognition of the factors of importance in any one district is a matter for geological investigation. Even when these factors are recognized, the work is not completed, for careful mapping of fissure systems, impervious strata, or favorable limestone beds is necessary to furnish a guide for exploration.

Impregnations.—By impregnations or disseminated deposits are meant those in which ore occurs in minute quantities scattered throughout great masses of rock. In this class are the 'porphyry coppers' that have attracted such great attention at Bingham, Utah; Ely, Nevada; in Arizona; and New Mexico. These ores are usually of value only when secondary enrichment has taken place. In the case of the copper ores at the surface, a capping of leached and more or less decomposed rock is found that may extend from fifty to several hundred feet in depth. Underneath this is a zone of secondary enriched ore that gives place to very poor, usually unworkable, sulphides. Even the richest part of these ores is usually so lean that it must be worked on a large scale, and extensive blocking out of the deposit by drilling or underground work must precede mining. The function of the geologist in these cases is to look for zones of fissuring that may have influenced the concentration of the ore, or that may affect mining, and to keep track of changes in depth and shape of the secondary zone, and to predict from these what may reasonably be expected in the future.

Among other types of ore that act in characteristic ways are magmatic segregations, bedded deposits, and lenticular deposits in schists and gneisses.

SECONDARY ENRICHMENT

It was not many years ago that miners rejoiced in the optimistic belief that every 'true fissure vein' grew richer in depth. This has given place to the modern conception of secondary enrichment which teaches that an orebody typically shows three zones, an upper or oxidized zone, followed by a rich zone of secondary sulphides, which gives place to leaner primary sulphides in depth. Many prophecies as to change of ores with depth are based upon the false assumption that this simple rule holds for all deposits. As a matter of fact, so many exceptions enter into the question that only careful study of every deposit will give a clue to what is actually the case. W. H. Emmons has recently shown that gold deposits act in different ways in regard to secondary enrichment, depending upon the presence or absence of manganese.³ D. C. Bard has called attention to the fact that veins with calcite gangue often show high content in the oxide zone and have no secondary sulphides.⁴ Even this last generalization has exceptions that make it dangerous to apply it blindly to all deposits.

In general, the extent in depth and the richness of secondary sulphides are dependent upon the amount of ore leached from the oxidized zone. It is therefore important to know how much of the oxidized zone may have been eroded in any particular case. I have heard of an engineer boldly prophesying that the secondary sulphide zone of

a certain property could not be of appreciable extent, because there was above it only a comparatively few feet of leached vein from which secondary ore could have been derived. He neglected entirely the possibility of hundreds of feet of leached vein-matter having been eroded.

Sulphide ores are sometimes found at or near the surface. It is then important to know to what extent they are primary ores, for the primary ores are likely to hold unchanged for much greater depths than secondary deposits. The methods of recognizing secondary enrichment have been best summarized by F. L. Ransome.⁵ Probably the most satisfactory method of investigation of this point is microscopic study of polished specimens of the ores, which often enables us to distinguish between primary sulphides and those formed by secondary deposition. There is an instance of a European mining company which was in doubt as to the advisability of proceeding with deep development on its sulphide ores. If the sulphides were secondary, the extent in depth was unlikely to warrant further work in such an inaccessible district; if they were primary, they probably represented such reserves in depth that a profitable mine was assured. The question was settled by sending specimens of the ore to an American geologist, who found by microscopic study that there was no sign of secondary deposition of sulphides.

In general it may be said that nowhere is the truth of the danger of a 'little learning' better shown than in the mistaken prophecies made by men who have only a superficial knowledge of secondary enrichment. This process, like all others involved in ore deposition, varies in its nature with local conditions. The texture and mineral content of the ore and wall rocks, the nature of the fissuring, and the geologic and physiographic history of the whole region are involved. The great importance of knowing whether the upper portion of an ore deposit is poorer or richer than the lower makes it well worth while to give considerable attention to local geology during the early stages of mining.

MISCELLANEOUS CONSIDERATIONS

Geological work may be of value in a variety of ways not mentioned above, and often in ways that the wisest engineer cannot foresee. An understanding of the relative age of the ore deposits and the igneous rocks is sometimes of importance, and may be deduced in an indirect way, as is illustrated by the following case.

In the case supposed the ore veins occur in a series of sediments that are cut by dikes and sheets of diabase, and also by stocks of granite. The question at once arises as to chance of the veins extending through the diabase. Comparison with neighboring districts shows that the mineralization is most probably the result of the granite intrusion, and examination of the district itself establishes the fact that the diabase cuts the granite and is distinctly younger than it. The diabase intrusions, therefore, may be expected to cut the veins, and not be cut by them, and claims underlain by great masses of diabase are less promising than those in which sediments predominate. The above conclusion is not as theoretical as it may seem, for economic geology has succeeded in establishing the ore-forming importance of certain intrusions and the barren character of others. In Arizona, for instance, most of the important copper deposits are connected with post-Paleozoic granites, and it is therefore reasonable to expect all formations younger than these granites to be found to be barren.

The value of geology in solving fault problems when the ore is cut off is well known, but it is customary to wait until the fault is intersected in the underground workings before paying any attention to it. In many cases a few days study of the surface geology will show the existence of faults, which from their strike and dip are likely to intersect and displace the orebody. With this in mind, the exploratory work can often be more wisely directed, and the discouragement of finding the ore unexpectedly cut off avoided.

Report of the Tonopah Belmont Development Company

The results of operations in the mines of this company, which is capitalized for \$1,500,000 in shares of \$1 each, for the fiscal year ended February 29, 1912, are shown by the following financial and statistical statements from the report of the president, Clyde A. Heller.

The net earnings of both mine and mill during the fiscal year were \$1,802,080.85, as compared with \$1,502,381.36. The operating expenses of the mine for the fiscal year, compared with the previous three years, were as follows:

indirect expenses (but not depreciation) for the fiscal year were \$293,840.13, as compared with \$239,568.95 for the previous year. The cost per dry ton milled, including indirect expenses (but not depreciation), compared with the previous three years was as follows:

	Dry Tons of Ore Milled.	Cost per Dry Ton Milled.
1912	87,349	\$3.36 4/10
1911 (10 months).....	58,624	4.08 6/10
1910 (8 months).....	37,166*	4.05 7/10
1909	61,929	4.37 9/10

*Includes custom ore.

During the year the capital stock of the company was reduced from 2,000,000 shares to 1,500,000 shares, par

DETAILED MONTHLY COSTS OF MINING, TONOPAH BELMONT.

The average actual extraction at the mill during the past year was 92.54% of the gross content, as compared with 89.4% in 1911, 89.9% in 1910, and 86.2% in 1909. The average value of the ore produced during the year, as compared with the previous two years, is as follows:

	1912.	1911.	1910.
Tons shipped to mill.....	87,952	59,159	29,898
Average gross value per ton....	\$20.84	\$27.58	\$14.40
Tons shipped to smelters.....	27,611	21,907	7,032
Average gross value per ton....	\$61.35	\$54.76	\$34.89
Total production (dry tons)...	115,563	81,066	36,930
Average gross value per ton....	\$30.51	\$34.93	\$17.99

The sales of ore, bulion, concentrate, etc., for the year were divided as follows:

Gold, 45,069 oz., sold for \$19.68 per oz.....	\$ 886,971.47
Silver, 4,535,762 oz., sold for 52½¢. per oz....	2,381,542.54

\$3,268,514.01

Less treatment charges, assaying, freight, and express

387,337.26

Total receipts

\$2,881,176.75

The operating expenses of the Belmont mill, including

value \$1 per share, and the 500,000 shares of the stock of the company in the hands of a trustee for the benefit of the treasury were canceled. The company's investment in stock of the Southern Nevada Abstract Co. was sold at a profit of \$1200. The increase in administration expenses over the previous year was caused principally by the increase in taxes paid during last year (which increase alone amounted to \$13,166.49), most of which is due to the United States internal revenue excise tax.

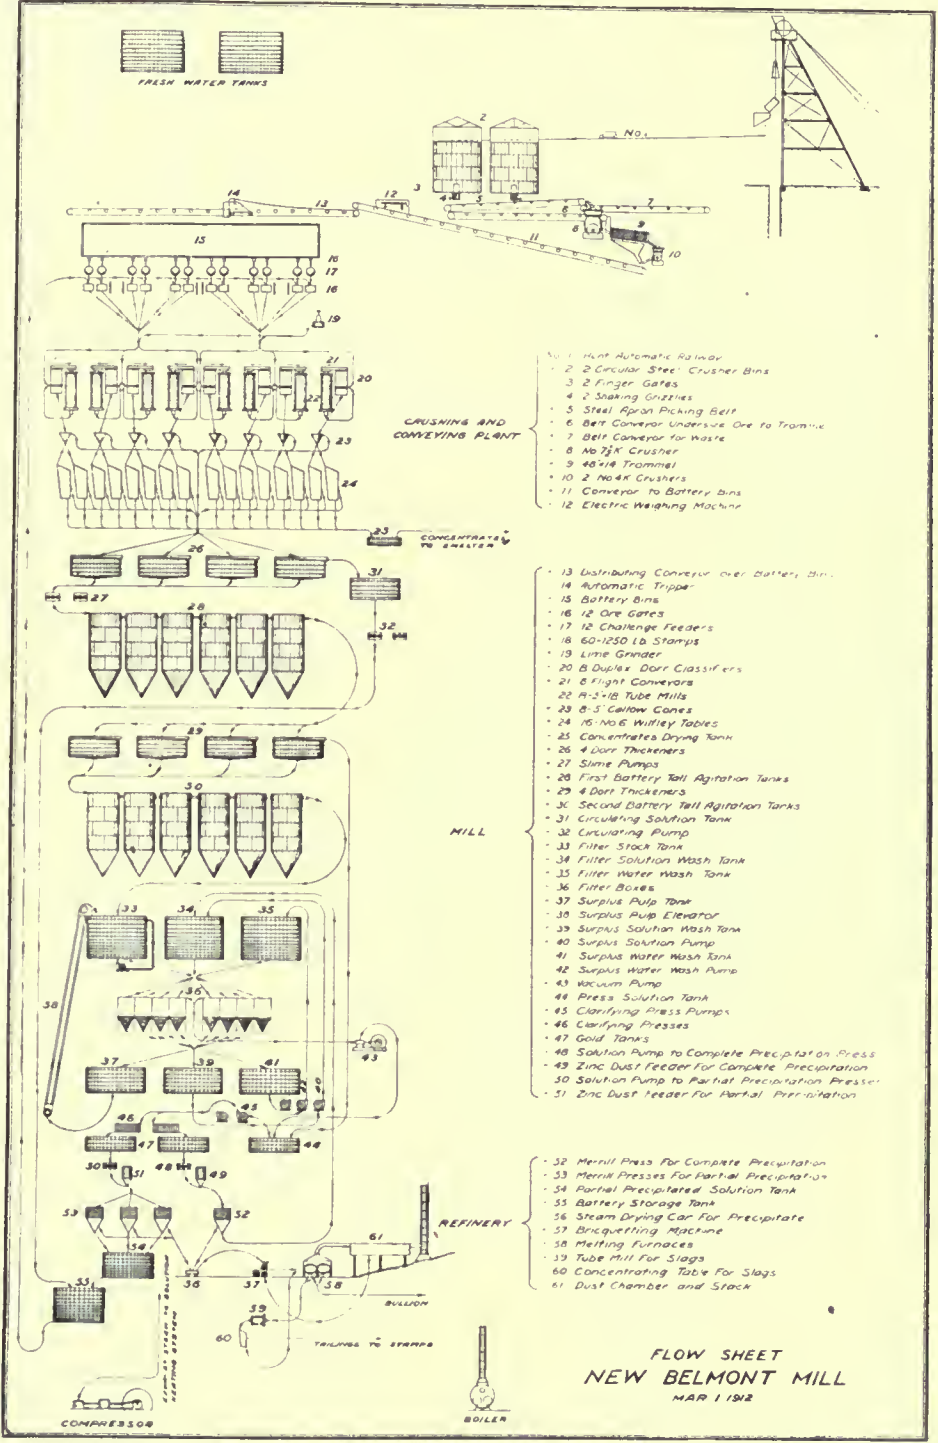

The project of a new cyanide mill at the mine, to take the place of the old mill at Millers, was authorized in June 1911, when it had become evident that the ore reserves fully warranted this large item of new construction. Ground for the new plant was broken in July, and by the end of that month the work of excavating was well under way. At the present writing the construction work, as described by Frederick Bradshaw, general superintendent, is progressing according to schedule, and, without interruption by bad weather, unforeseen accidents or delays, the plant should be in operation by June 15. The cyanidation of ores has been improved wonderfully in the five years since the construction of the mill at Millers, and an extended experience with Belmont ores at the old mill has shown the best metallurgical practice to be fol-

lowed in a new plant. Much painstaking thought and effort has been devoted to the metallurgical and mechanical construction of the new mill, and upon its completion it will be one of the finest cyanide mills in the country.

Briefly, the new milling plant will consist of a crushing department, the mill proper, a separate refinery, transformer house, boiler-house, store-room, and assay office, with other small auxiliary buildings and tanks, as shown by the accompanying flow-sheet. Resultant economies in transportation and reduction with the new plant in operation, as compared with similar items for the previous year, will be at least \$2.50 per ton, while the capacity of the plant will be, at the lowest estimate, 165,000 tons per annum. The new mill will obviate entirely the shipment of ore to the smelters, and will also allow the extraction and reduction of ores of a grade lower than are under present conditions profitable. The capital outlay for the plant should be returned, in the form of reduced costs, in a year and a half or less of operation, after which a large net saving should accrue. While the freight and treatment on mill ore to the Millers plant averages at present but \$4.619 (\$3.879 treatment plus 70c. freight, plus 4c. toll over Montana spur) on \$20 ore, it is to be considered that on all ore shipped to mill and smelter the freight and treatment charge (average for year) is greatly higher, \$6.449 per ton. The new mill should save, on a tonnage of ore equal to that shipped during the past year (114,960 tons), \$287,400, and should save during its first year (on say 165,000 tons treated), \$412,500. The estimated cost of this mill is \$435,000, of which \$292,304.17 has been expended up to and including February 29, 1912. The capital outlay will almost be returned during the first twelve months of operation. Efforts are being made to obtain a sufficient tonnage of custom ore from other mines to justify the operation of the old mill after the new mill shall have been completed; but as nothing definite has yet been obtained the management deemed it prudent to write down the value of the old mill as carried on the books by over one-half, or \$232,500. Of this amount, \$82,500 has been taken from 'Reserve for Depreciation' and the balance \$150,000, from 'Special Reserve.' During the coming year, if it is found impossible to keep the old mill in operation, its value will be written down to the actual scrap value.

The amount paid during the fiscal year on account of the mine fire of February 23, 1911, is \$48,633.12, which pays in full all claims of relatives of those who lost their lives in the fire (without recourse to the courts) except in three cases. In these three cases the amounts have been agreed upon, although, on account of legal formalities incident to obtaining proper releases, and signing of

papers, actual payment has not yet been made. There has been no change in the acreage of the property, which consists of 11 claims, a total of 116.55 acres. An admirable feature of this report is the detailed monthly statements of mining and milling costs, given herewith. The combined income account of the mine and

mill for the year ended February 29, 1912, is as follows:

Administration expenses	\$ 40,555.93
Losses and expenses incidental to fire in mine ..	48,633.12
Surveying and other preliminary expenses for mill-site	4,040.81
Adjustments of prior years' accounts	745.90
Dividends paid to shareholders:	
No. 7, Feb. 27, 1911, 25%	\$375,000.00
No. 8, May 11, 1911, 25%	375,000.00
No. 9, Aug. 28, 1911, 25%	375,000.00
No. 10, Nov. 27, 1911, 25%	375,000.00
	1,500,000.00
Balance of net income, available for the payment of dividends or otherwise	1,487,948.15
	\$3,081,923.91

Mining at Jarbidge

By AN OCCASIONAL CONTRIBUTOR

In the past year Jarbidge has developed somewhat, but far from the extent expected. At the present time it may be said to have passed into a state of innocuous desuetude, from which cataleptic condition it may revive in two months or it may take two years. For the present there is no money in the district, very little work going on, no chance to make any money, and little prospect of collecting any bills. Many people are leaving.

The trouble with Jarbidge has not been with the mines so much as with the owners, who have displayed so much stupid ignorance and greediness, or have attempted too much work on no funds. Bad checks seem to have been the regular working capital of most of the companies, which has left the district in a very bad state financially. Besides the many small outfits which have paid off their laborers with checks drawn against a bank with little or no money to their account, the two big companies, with their all but useless mills, suddenly suspended a short time ago, each of them having an unpaid labor account of \$7000 or \$8000 which is still unpaid.

But perhaps the worst setback is the greed of the property owners who want to get a fortune for a fair prospect and who thus prevent any solid mining men from securing a foothold. They think because they find a few pieces of high-grade ore in a prospect-hole that they have a bonanza mine, and immediately want a mine price for it. There have been some good people in Jarbidge who were favorably impressed with the prospects and were willing to take hold on any reasonable basis, but who re-

fused to invest when they were asked such unreasonable prices as \$125,000 for one 10-ft. hole, \$250,000 for a three-fourths interest in three 10-ft. cuts, \$150,000 for an eight-tenths interest in two 10-ft. holes, and similar equally impossible prices.

George Wingfield did take hold of two of the good-looking properties, even at these high prices, one of them running up to over half a million. But then it is to be presumed that he counted on his previous acquaintance with the owners to get the mines later at a price compatible with the development. After spending nearly \$50,000 in development on the two properties and opening only about \$150,000 worth of ore of a fair milling grade, he wished to have the price brought down to a reasonable one, and, meeting with refusal, he decamped. And it is fair to predict that all other moneyed men will stay out and wait until prices come down to somewhere near the probable value of the properties. This will also necessitate that the owners come to a realization of the fact that the veins are only of moderate size and that the ore is of a \$12 milling grade, rather than a \$200 bonanza quality, as they have thought.

The best-looking prospect in Jarbidge today is the Flaxie, which on the 85-ft. shaft level has a drift over 225 ft. long in a continuous ore-shoot, with a width of 3 to 5 ft., which assays from a few dollars to over \$50 per ton, with a probable average about \$17 per ton. This is the longest and most regular ore-shoot yet opened in the camp. This is now under bond for \$60,000, which is the most reasonable price set on any of the properties upon which good ore has been found. Work is still continued on the Jarbidge Gold, adjoining the Flaxie, but as yet it has not reached the vein in the solid formation. On the Alpha considerable work is being done in several places, and two or three feet of good ore is being opened up.

The double-track development adit on the Log Cabin is going ahead. As soon as the roads are in condition for heavy freighting, machine-drills will be employed there and the work pushed.

There is talk of a small custom mill in the canyon near town. This seems to me to be the best possible thing—a small mill turning out bullion at a profit. There is plenty of \$20 to \$40 ore that can be packed down from the Bourne and Flaxie to keep a mill busy; besides, there are numerous other properties which could use such a mill for a trial run to establish the value of their ore. This sums up the present condition of a sometime-in-the-future producer.

Work of the Nevada Consolidated Copper Company

By POPE YEATMAN

*This report covers the fifteen months ended December 31, 1911, representing the third year's operations of the Nevada Consolidated Copper Co.; the additional three months being due to a change in the fiscal year, previously ending September 30.

Property.—No addition to the area of the mining property has been made during the past year except in the way of certain claims to be utilized solely for the purposes of disposing of overburden from the section to be mined by steam-shovels. While the company had sufficient ground for the disposition of this material, the purchase of additional area was thought advisable on account of it being possible to dispose of the stripping at a lower cost. The claims consist of the Stillwater No. 2, 3, 4, and 5, amounting to 60.5 acres, and allow for the disposition of 3,750,000 cu. yd. of waste. In addition dumping privileges have been obtained on claims belonging to the Coppermines Co., covering an area of 15.3 acres, and providing for the dumping of 1,265,000 cu. yd. of waste, measured in place.

Prospecting.—Considerable work has been done with churn-drills in order to determine the limits of the ore-bodies, both laterally and in depth. While these limits were already fairly well known, there were still a few gaps for which more complete data were required to enable the company to fill out the boundaries more accurately. Fifty-one holes were drilled, amounting to 17,185 ft. In this footage, however, is not included drilling in the steam-shovel pits for blasting purposes. The total number of holes to date, including the Cumberland Ely holes, is 258, amounting to 78,872 ft. Prospect drilling in the last year was carried out on Ruth, Eureka, Hecla, and Liberty areas.

As a matter of special interest, hole No. 76 was drilled in the Eureka pit to a total depth of 680 ft. below the original surface, far into the primary ore, to determine if the low-grade material, less than 0.4% copper, was local or if the real primary ore had been finally penetrated. The latter is believed to be the case.

Ore Reserves.—During the past year the ore reserves have been added to, but these additions were proportionately not so large as during the previous year. The ore now developed and its estimated assay value is as follows:

	Tons.	Average % Cu.
Total developed ore, to Jan. 1, 1912.....	49,410,087	1.705
Unprofitable account slopes.....	1,419,300	1.212
		<hr/>
Total profitable ore developed.....	47,990,787	1.716
Ore milled to Jan. 1, 1912.....	7,137,416	2.041
		<hr/>
Profitable ore remaining in reserve, January 1, 1912	40,853,371	1.662

Mining.—As in other years, all mining has been done by means of steam-shovels, and this work continues to be carried on most satisfactorily. Much the larger portion of the ore mined has been from the Copper Flat or Eureka pit. During the last few months a considerable tonnage has been extracted from the Liberty pit. The deepest point reached in the Eureka pit is about 115 ft. below the main tracks, or approximately 137 ft. below the capping. This point is well below the water-level, but the amount of water has been too small to give any trouble.

In December, after having been idle for over two years, the Veteran mine of the Cumberland Ely was re-started and a small amount of ore was mined underground. During the fifteen months period the following dry tons of sulphide ore was mined and shipped to the concentrator:

	Tons.	Average % Cu.
Eureka pit	3,261,482	1.790
Liberty pit	62,956	1.768
Veteran mine	5,584	3.050
		<hr/>
Total	3,330,022	1.791

The ore mined was of lower grade than for the year preceding, due to the fact that more ore was taken from the fringes of the deposit, from greater depth, and from sections which had previously been considered as waste, but with the reduced cost of concentration, was found to be profitable. During the year silicious carbonate ore amounting to \$205,795 dry tons, averaging 2.91% copper, was mined, of which 39,235 tons was crushed and delivered to the smelter, and 166,560 tons was put into mine storage. As was the case the previous year, this ore was mined faster than the requirements at the smelter demanded, but it was necessary to take it out in the course of removing the overburden. It has been stored to supply the future needs of the reverberatories and converters.

Stripping.—The overburden removed during the year has been taken from three sections, namely, the Copper Flat or Eureka, the Liberty, and the Hecla, in the following amounts: Eureka, 1,734,313 cu. yd. overburden, 50,158 cu. yd. approaches, total 1,784,471 cu. yd.; Liberty, 1,347,927 cu. yd. overburden, 5000 cu. yd. approaches, total 1,352,927 cu. yd.; Hecla, 111,742 cu. yd. overburden; grand total, 3,249,140 cubic yards.

Including waste material to be taken out in the stopes, the following is the estimate of cubic yards of stripping remaining to be removed: Eureka, 837,900; Liberty, 6,760,600; Hecla, 5,050,500; total, 12,649,000. There has been removed a total of 6,038,683 cu. yd. of stripping to January 1, 1912. At the Eureka or Copper Flat pit the capping directly above the ore has been entirely removed and also a large portion of the waste material in the slopes. Stripping of overburden on the Hecla was started during the fiscal year, but sufficient capping has not been removed to reach the ore itself. Stripping is sufficiently advanced on all three sections to allow an extraction of sufficient ore to meet the requirements of the concentrator. There are now in operation in the pits eight steam-shovels, of which one is held in reserve and the others used either on the extraction of ore or removal of overburden.

The three working places show a variable thickness of profitable ore and thickness of capping as follows:

Place.	Av. thickness of profitable ore, ft.	Av. thickness of direct capping, ft.
Eureka	190.0	87.1
Hecla	280.3	101.4
Liberty	193.3	154.7
		<hr/>
Average	217.9	102.5

Costs.—Including charges of every description, such as labor, supplies, repairs, management, taxes, proportion of general and New York expenses, etc., the mining costs have averaged 15.7c. per dry ton. An additional charge of 15c. per ton of ore has been made to cover stripping redemption on the Eureka orebody and 22c. per ton on the Liberty orebody. These charges are based not only on the cost of removing the overburden directly overlying the ore to be mined, but also such waste as will have to be removed to allow for safe working in the bottom of the orebody. In other words, to allow for proper slopes in the shovel pit. Stripping costs have been reduced to 36.3c. per cubic yard. The cost for mining carbonate ore has been 74.40c. per wet ton, the increase being largely due to more care being necessary in sorting.

*From a report made to the Directors of the Nevada Consolidated Copper Co., February 14, 1912.

General.—Improvements during the year have been the acquiring of one new locomotive and one 95-ton steam-shovel, construction of numerous tracks to connect the steam-shovel pit with different dumping areas, building additional quarters for married men, schoolhouse, locomotive and car repair-shops, carpenter-shop and bunkhouses, ten Italian quarters, staff-house, hospital, two powder-houses, eight Greek dwellings, etc. The 18-yd. dump-cars and three new locomotives mentioned in the last report were delivered during the year and have been put into service.

Transportation.—Transportation of ore from the mine to the Steptoe Valley plant, has been most satisfactory, and owing to the increased equipment, there has been no delay even during the severe winter months.

Steptoe Valley Smelting & Mining Co.—The plant has worked very successfully during the past year and has shown considerable increase in capacity. Greater efficiency and a decrease in the cost of operating has resulted. A great reduction has been made in the cost of concentration, amounting to 15.9c. or 25.72%. This is due, in the main, to treating a larger tonnage of ore per section. Power costs were also reduced, and in fact there was an improvement in the way of costs in all departments.

Concentrator.—As will be seen from the table, extraction was lower than during the previous year, due first, to a reduction in the grade of ore treated; and second, to perhaps crowding through more ore than would have been the case had the grade been higher. The reduced costs, however, much more than make up for the decreased percentage of extraction. A most interesting test was made during the months of May, June, and July, which proved in working with large tonnages that ore of a very low grade, much lower than had been believed, could be treated at a profit. The test was made on a tonnage of 256,000. The following table shows, by months, tonnages treated, assay of ore, percentage saved, and ratio of concentration:

result from this. The main changes made in the plant have been in the direction of increased settling devices to allow the utilization of a greater amount of return water. One section of the concentrator was altered so as to allow for treatment on the lines of the Utah Copper Co.'s flow-sheet.

Roasting Plant.—No additions have been made to this plant, but there have been some improvements made in the operations of the furnaces, and the cost of roasting has been reduced 8.3c. or 12.71% per ton of concentrate.

Reverberatories.—During the year 1911 very important changes have been made in the reverberatory operations, and the capacity of the furnaces has been greatly increased and costs considerably reduced. This improvement has been due to the change of fuel from coal to Coalinga oil. The charge per furnace-day has been increased from an average of 223.53 tons per day in 1910 to 359 tons per day for the month of December 1911, and the costs shown for the year 1910 have been, for the month of December 1911, lowered by 63c. per ton charge, or 24.31%. The whole 15 months is not included for the reason that the change to oil burning was not made until some time in 1911.

Converting Plant.—Improvements have also been made in the converting plant, principally by the change from acid-lined converters to those lined with basic brick, and also to the introduction of the Pierce-Smith converter. Greater capacity is obtained and a reduction in cost; but not having finished the entire installation of the Pierce-Smith converters, the full benefit of the improvement has not been determined.

Power-House.—Improved efficiency has resulted in considerably lowering the cost of producing power. No changes have been made during the year other than equipping some of the boilers with oil-firing devices.

Water.—Work has been continued at Duck creek in order to conserve a greater amount of water, and this has resulted in a somewhat increased flow for the Steptoe

% Copper in Concentrates.....	13.03	11.59	11.92	11.58	16.11	18.45	15.02	14.18

The results for the fiscal period (15 months) were as follows:

Tons of ore treated (dry).....	3,338,242
Average copper assay, per cent.....	1.80
Per cent Cu extraction.....	67.59
Ratio of concentration.....	11.34
Assay value in gold, oz.....	0.013
Assay value in silver, oz.....	0.079
Per cent gold extraction.....	57.72
Per cent silver extraction.....	45.92
Average Au and Ag recovered per ton ore, cents	17.35
Average per cent copper in concentrate.....	13.80

A good deal of experimenting has been done during the year in the direction of greater efficiency and extraction. During the month of November a complete concentration test was made, under the direction of Allen H. Rogers, who reported fully concerning the work done by several different methods, and it is hoped that much good will

plant.

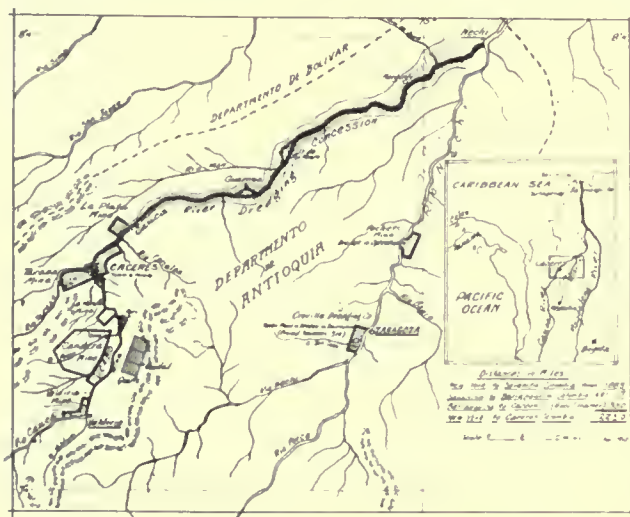

General Improvements.—These included a new warehouse and a new Nordberg return-water pumping engine of 5000 gal. per minute capacity, at the concentrator, installation of a fuel-oil system with 25,000-hbl. tank, several extra quarters, and a new clubhouse for the employees, dormitory for teachers, and increases in the fire lines and general water service. The property has been added to during the year by the purchase of the Payne ranch and water rights on Duck creek consisting of 320 acres.

Production and Costs.—The yield from all ore mined and treated, and from silicious carbonate ore delivered to the smelter, has amounted for the 15 months to 78,541,270 lb. of copper. The total cost per pound of copper has been 7.17c.; and deducting miscellaneous earnings, but including fund to cover improvements and depreciation, this is reduced to 6.97c. These costs include all possible charges, such as costs in Nevada, shipping, refining, marketing, legal expenses, taxes, and New York expenses.

Conclusion.—The period under consideration has been a most successful one and has resulted in very material reductions in the cost of operating and of production per pound of copper—even on a lower-grade ore than during the previous periods. The most important features have been the reduction in milling costs and increased capacity of the concentrator, installation of oil-firing for the reverberatories resulting in reduced cost, and improvements in the converting due to the introduction of basic-lined converters. I wish to commend C. B. Lakenan, the general manager, and his staff for their continued display of progressiveness and efficiency, and for the loyal work on behalf of the company.

Dredging at Pato, Colombia

The Pato Mines, Ltd., owns a concession of 22,000 acres on the west bank of the Nechi river, Colombia, six miles from Zaragoza in Antioquia. Of the 560,028 shares of £1 each which have been issued, three-quarters are held by the Oroville Dredging Co., Ltd., which has loaned to the Pato company \$534,129 on 8% income notes for equipping

MAP OF THE PATO DISTRICT, COLOMBIA.

the property. At the annual meeting of the Oroville company held in London on March 30, F. W. Baker, chairman of the board of directors, said: "I think, gentlemen, it has been made clear to you that as soon as these advances, against which 8% income notes have been issued by the Pato Mines (Colombia), Limited, are paid off out of the profits of the Pato company, the funds so set free in this way will be available for distribution by the American company to its shareholders to the extent of the surplus earnings of that company, and that we shall be in a position to draw upon these surplus earnings for the first dividend of the new series by the spring of next year, with every prospect of maintaining dividends uninterruptedly thereafter. I would like to draw your attention to a paragraph in the directors' report to the English company dealing with an aspect of our Pato enterprise, which, in my opinion, is of great importance. I refer to the reference on page 5 of the report dealing with the portion of that property susceptible to hydraulic methods, known as the 'California Hill.' I do not think I can do better than read that portion of the directors' report, because it deals very clearly with two interests that we have outside of the 300 acres of what we call proved land, which may develop into something of considerable importance in our interests in the future. We have thereabout an additional 400 acres of dredgable ground, which our management on the spot have told us they think will prove to be good ground. We have not yet tested it thoroughly, and for that reason we are not prepared to say much about it, but it certainly holds out the hope that when we have exhausted the 300 acres, which we propose to work out as soon as our equipment is completed, we

may have still another 400 acres of ground which our management think will prove to be good dredgable ground. One of the reasons that the equipment down there is being made as complete and as strong as it is, is because the management feel that we have got other assets which will not be exhausted within the seven years that it will take to work out these 300 acres, and they are really providing for the future in that way. Further, we have another asset down there which may be exceedingly interesting—how interesting, nobody can say. We have on the property what is known as the California Hill, forming a portion of the 400 acres I have just referred to. This is a big block containing probably millions of tons of gravel. A trial run of 9000 odd yards of this gravel was made, taken from different points on this California Hill, so as to try to arrive at what might be considered, even in that small way, a fair sample of the gravel. We got a result of 34.7c. from the washing of 9000 yards. That is a very high figure for a hydraulicking proposition, because that is what this would become if we found it had any merit in it at all. A 10c. ground in California has always been considered good pay-dirt, and unless we are up against conditions here which would make the operation and working of that property impossible, or so costly that it could not be carried out at a profit, we may find that we have got in that hydraulicking proposition, apart from our dredging interest, something of considerable value. Unfortunately, the 300 acres lie immediately at the foot of this California Hill, so that we could not even temporarily get a head of water in and find a method of disposing of our tailing. We could not start immediately, because the probabilities are that the tailing would go over this rich gravel ground which we propose to dredge. It is our intention to send out an expert to have this hydraulicking proposition thoroughly considered. If we get a satisfactory report, we may have to delay working it until we have cleared away enough ground for our dredge to make a dumping ground for the tailing in the hydraulicking portion. Anyhow, I think we can make up our minds that in the Pato property our resources are not absolutely limited to the 300 acres which have been proved and tested, and which we will work with this dredge that we have now put on the ground. That, in my judgment, adds a speculative value to our proposition, which time and development may prove to be a reality."

Keeping Gold Out of Concentrate

By GEORGE A. JAMES

A generally accepted theory of mill practice is that it is of minor importance in which part of the metallurgical process gold is recovered, if the amount does not vary, and apparent costs remain the same. The outward evidence of this belief is the elimination of amalgamating plates and amalgamation in general. It is assumed that gold that should be amalgamated will be obtained by concentration or subsequent leaching. Although this assumption can seldom be admitted, it is my purpose to show a surprising loss in net returns, even though the gold recovery does not vary in quantity. An argument advanced against amalgamation is the loss of crushing capacity owing to delays for clean-ups and dressing plates. It is my belief that amalgamators exist that overcome this objection, but if such is not the case, an extra amalgamating unit could be provided to carry the load while clean-ups are made. Admitting that both of these methods are impossible, and 10% is enough to allow for decreased crushing capacity, this would seldom add 5c. per ton to the cost of ore treatment.

I shall first indicate the advantage of amalgamation where concentration is employed and the concentrate is shipped to ore purchasers. Let us assume ore worth \$20 per ton and that 10 tons have been concentrated into 1. The ton of concentrate would contain \$200. The percentages usually deducted would be 8.2 (5% of assay value and gold at \$20 per ounce), or \$16.10 per ton of con-

centrate, equal to \$1.61 per ton of original ore. In addition to this, there are various charges not so apparent, but which amount to considerable importance; such as leakage from sacks in shipment and portions adhering to emptied sacks. Such leakage will certainly come to an average of 3 lb. per sack. Allowing 15 sacks to ship the ton of concentrate, 451 lb. would thus be lost, which at 9c. per pound would represent a loss of \$3.95. In grinding samples in disk pulverizers (as the custom is to reduce to 100-mesh or finer), $\frac{1}{2}\%$ or more of iron enters the sample, which, of course, deducts that much from the assay value. The commercial assay is usually $\frac{1}{2}\%$ below corrected assays, and in determining moisture the buyer always 'plays safe.'

Considering these details, it will be seen that the ton of concentrate has returned \$178.60, not including freight and treatment charges, or 89.3% per ton of original ore, equal to a treatment cost of \$2.14. Let us assume that 50% of the gold could be recovered by amalgamation and that the extra cost of treatment is offset by factors not included in estimating the expense of shipping the concentrate to the reduction works. Under this head might be mentioned extra control assays, increased freight charges (which are usually regulated according to the value of ore shipped), interest on money locked up in settlements. The expense charge is about 5c. per ton for refining of gold and expressage. The account under these circumstances would then stand:

Amalgamated gold, net.....	\$ 99.50
Gold shipped	89.30

Total	\$188.30
-------------	----------

Or \$1.02 per ton in favor of this manner of handling. Against this should be charged the interest on investment required to obtain equal capacities.

An example of cyanide or chlorination treatment with the same ore would be approximately as follows. It is not too much to assert that the gold most easily amalgamated is least susceptible to leaching methods (as it consists of the coarser particles), and where 50% could be amalgamated, total extraction would be reduced, at least 2%, and the time of treatment necessarily increased. Such being the case, the comparison would then be:

By leaching:

50%, with 97% extraction.....	\$ 97
50%, with 90% extraction.....	90

Total net return	\$187
------------------------	-------

By amalgamation*:

50%, with 100% extraction.....	\$100
50%, with 97% extraction.....	97

Total net return	\$197
------------------------	-------

Thus showing a profit of \$1 per ton of original ore treated. This article is merely intended to attract attention to the principle involved, and to a common source of error.

GOLD is found in the alluvial sands in many districts of Siam, and is washed out in small quantities by the natives. The Kabin gold mine, in eastern Siam, was taken over by an English company some years ago, but, although the mines were worked to their full extent under the supervision of Cornish miners and Scotch engineers, no results were obtained and the company failed. Up to the present, the working for gold in Siam by Europeans has not been successful, and the native gold-mining industry is of little importance.

TIN is one of the minerals workable deposits of which are lacking in the United States. The production in 1910 was valued at only \$23,447, according to the U. S. Geological Survey, while imports were worth \$33,913,255.

*It is assumed that refining and express costs remain the same in case of gold recovered by both amalgamation and leaching, although it is usually in favor of amalgamation.

Goldfield Consolidated Report

The total production of the Goldfield Consolidated Mines Co. during March 1912 was 30,132 tons, containing \$734,655.98, or an average of \$24.38 per ton, according to the report of J. F. Thorn, general superintendent. This was milled with an average extraction of \$22.92 per ton, or 93.99%. The total net realization was \$491,337.30, or \$16.31 per ton.

During the month 2719 ft. of development work was performed. The total cost of mining, development, milling, office, and general expense was \$6.66 per ton, distributed as follows:

Mining:

Development	\$0.80
Stoping	2.55

Transportation	\$3.35
Milling	0.08
Marketing	2.11
Marketing	0.11
General expenses	0.49
Bullion tax	0.19
Construction	0.33

Total cost of operation	\$6.66
Miscellaneous earnings	0.05

Net cost per ton.....	\$6.61
-----------------------	--------

The sill of the 428-stope between the third and fourth levels of the Clermont was again extended and produced 53 tons of ore averaging \$26.45 per ton. The 604-raise from the 1000-ft. level going up to the 534 on the 900-ft. level, and the stope being opened from the raise, produced 916 tons, averaging \$56.34 per ton. The 700-M stope being opened between the 1000-ft. level and the 1200-ft. level from the 700-D winze produced 63 tons, averaging \$45.47 per ton. The 111-M sill of the Mohawk produced 524 tons, of an average value of \$13 per ton. The 212-X cross-cut on the 350-ft. level near the 260-stope produced 53 tons, averaging \$69.52 per ton. The 208-X intermediate being driven under the 111-sill at the south end near the old Truitt shaft produced 30 tons, averaging \$48.60 per ton. The 354-sill was extended and produced 198 tons of an average value of \$74.40 per ton. The 491-sill cut out of the 415-X between the third and fourth levels, and under the old Mohawk-Jumbo lease workings, produced 436 tons, averaging \$17 per ton.

The 353-intermediate between the second and third levels of the Red Top was again extended in ore and produced 151 tons, averaging \$32.50 per ton. The 216-N raise from the second level just north of the shaft produced 130 tons of an average of \$63 per ton. The vertical raise from the 750-ft. level of the Hazel has holed the bottom of the Laguna shaft, and is being squared out and the shaft timbered down to the bottom. The Hazel shaft surface plant will then be dismantled, and all deeper development in this territory carried on through the Laguna shaft. In the Combination mine rather an important discovery has been made between the fourth and fifth levels, in the Riley vein, about 300 ft. southeast of the shaft. The 311-P raise from the fifth to the fourth level produced 140 tons of ore, averaging \$86.60 per ton. The upward extension of this ore-body was cut in an intermediate between the second and third levels, where two hanging-wall cross-cuts 60 ft. apart exposed 7 ft. of ore which averaged \$250 per ton. The 292-O sill was extended and produced 69 tons averaging \$25.60 per ton. The 328-sill produced 41 tons averaging \$20 per ton.

THE gold production of Bendigo for the week ended February 24, 1912, amounted to 2496 oz. 9 dwt. The principal contributors were South New Moon, 320 oz. 12 dwt.; Hercules and Energetic, 197 oz. 16 dwt.; Ironbark, 167 oz. 3 dwt.; Central Red, White, and Blue, 142 oz. Central Red, White, and Blue announced a 2s. dividend, amounting to £3200, their total profits to date being £76,800.

Discussion

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Insertion of any contribution is determined by its probable interest to the readers of this journal.

Is 'Cheap' Labor Economical?

The Editor:

Sir—The important point in regard to native labor is the cost. If an ordinary development adit can be driven for as many pesos per foot, in Mexico, as it costs dollars in the United States, why is Mexican 'cheap' labor not satisfactory? I have often seen this done in Mexico, using Mexican labor entirely, only the one 'white man' in charge. It is the man in charge and how he handles his labor that counts. Many make the mistake of trying to make the Mexican do everything as directed, not realizing that for 300 years the average Mexican miners' ancestors have been miners, and they will often accomplish more if the foreman is not too arbitrary with them. When a pair of them will drill 12 ft. for a shift's work in a hard Gunnison county granite, in a 75-ft. raise, where the air is so bad that 10 and 12 candles per shift are necessary, a day's wages of \$2.25 each ought to be satisfactory.

I have known a Mexican miner to make better than wages on a contract, at \$3.50 per foot, driving an adit in a tough diorite, tools being furnished him, he buying his powder and doing his own 'mucking.' He and helper would go in after a round of shots, with an 8-lb. hammer and a 'bar punta' (a 6-ft. piece of drill-steel, sharpened to a round point at both ends) and break down more rock than one would believe possible, until he had seen it done. Rock broken by a good *puntista* is the cheapest broken in a mine; it is always profitable to use one where possible. My observation and experience has been that you do not want to 'cuss,' damn, or kick the Mexican laborer when his work is not satisfactory; give him his time—life is too short to quarrel. The chances are that in two weeks you can hire him again and he will prove a good man.

Any foreman who is continually showing his men how to work, whether a 'white man' or Mexican, should get his time, as every man in sight or hearing will be idle watching him, and they will find excuses to get him to show off. If he can't tell by going to the face of a drift twice a day whether a day's work has been done or not, it is better to get one that can. Whenever it is possible, work the Mexican by task work, pay him for what he does, per foot of drilling, or per ear, wheelbarrow, or *zuron* carried on his back up a chicken-foot ladder; he will do more work, cheaper, and be far better satisfied. At Batopilas, a number of years ago, when machine-drills were first introduced, several American miners were brought in to run them. The Mexican helpers soon became very efficient, have given the best satisfaction, and are by far cheaper. The Mexican learns quickly by observation. There often are 500 to 600 men underground in the mines at Batopilas; for a number of years the only foreigner has been the mine superintendent.

It is absolutely necessary that the 'white man' in charge shall speak the language well; it is not sufficient that "I can make myself understood," as it is possible, sometimes, to understand a fenderfoot by the sign language; the foreman must be sufficiently proficient so that he knows he is always understood. The workmen invariably lead you to think they understand; later, to your cost, you find that they did not. I believe, on the average, that ordinary mining operations can be carried on in Mexico for one-half the cost in the United States. Not that this is always or even generally done, but it can be done by proper handling of the labor, and good management. I have seen \$1000 per month expended on management, superintendence, and office expenses when only working eight or ten pairs of miners; but that is not legitimate mining.

Ely, Nevada, April 15.

G. L. SHELTON.

Protection of Investors

The Editor:

Sir—Your editorial in the number of March 16, entitled 'The 'Blue Sky' Law,' merits the approbation of all, and it would be, as you say, a desirable condition if each of these United States had upon its statute books a law similar to that of Kansas. There would be, however, one or two practical difficulties in carrying out this program literally. For example, it would be difficult to comply with the requirement by the state that the company seeking subscription pay the expenses of a thorough examination. In the case of any large industrial undertaking, such an examination is costly, and were each state to require an independent examination, the total cost to any company would be prohibitive. An easier way to secure the maximum degree of safety to the subscriber would be, it seems to me, to require issues, that may be offered for subscription to more than a certain limited number of persons, to be underwritten by parties satisfactory to the bank commissioner's office. The effect of this would be to guarantee a proper investigation, because no party satisfactory to the commissioner would underwrite the issues of a company with the risk of having to purchase them, who had not satisfied himself that the value was behind them. In this way, the promoters would have the expense of but one examination to pay in order to enter any number of states. The Kansas law, if enacted by many states, would, without doubt, prohibit the promotion of many meritorious enterprises.

Another difficulty in a multiplicity of such laws would be the regulations as to bookkeeping. This, of course, would not be a difficulty where all the states adopt the same regulations, but that is almost certain not to be the case, at any rate, as to form. The filing of the statement of the company's affairs down to the minutest details is, of course, an admirable feature, and, among other things which should be specified, ought to show clearly the promotion profits and all payments, whether of cash or securities, for property, patents, good will, etc., after the manner of the English law. The foregoing applies, of course, to the flotation of a stock company for any sort of operation. It applies to the formation of a company for working a mining property whether this be a mere prospect or a developed mine. But there are certain aspects of mine company promotion which will bear elucidation and discussion, some points bearing on fraudulent promotions which, I believe, have never been brought out.

The principal reason why the Government made so poor a case against Rice and Scheffels was that a large part of the representations of these promoters was opinion. Now, with respect to a prospect—that is, a property which shows no value, but promises to be of value—two different men hold two very different opinions as to its worth, and each may be thoroughly honest in his opinion. As long as this is the case, no promotion of a company to work a mining property can be proved fraudulent, for the only promise of success must be based on someone's opinion, and it is impossible to prove that such an opinion is not honest. The fact that certain production and profits are promised but not realized cannot be alleged as evidence of ill-faith, even though a competent judge of such matters could have said from the start that they were impossible of realization. The guarantee which the intending subscriber must demand under present conditions is that the opinion on which the promises are made be that of an engineer whose record shows that his opinions are of value.

Mining promotions may be divided broadly into two classes—one where the property is but little, if any, developed, and hence a 'prospect,' the other where the mine is sufficiently developed to assure a successful operation. In the latter case, the object is, generally, to provide capital for plant, etc., and is, of course, a simple business proposition, depending only on the valuation which is put upon it. Such promotions are often underwritten, and the underwriters are guided by good engineering advice. The engineer in his report gives facts and figures showing profits, so that the subscriber can figure for himself the value of

his investment. The only question in this proposition is as to the honesty of the engineer and his ability to estimate correctly the amount of ore, the cost of working, and the future of the mine. As these questions vitally concern the underwriting, the underwriters are, naturally, much concerned in satisfying themselves as to these qualities of the engineer, so that, with responsible underwriters acting, so to speak, as the agents of the subscribers, the latter can generally accept such underwriting as a guarantee of safety and good faith. The profits to the subscriber to this sort of flotation may be only small, but the risk is small, also.

In the other class of promotions, namely, the prospect, absolutely no guarantee can be given. The basis for the undertaking must be the opinion of somebody that the property, when developed, will contain a valuable body of ore. And that is as far as anyone competent to express such an opinion can go, for it is manifestly absurd to predict what tonnage of ore will be opened when no means exist for determining the dimensions, what the value will be when no samples can be taken, and what the profits will be when no knowledge exists of the character of the ore, of its amenability to treatment, or of the ground in which it occurs. So that, it may be safely assumed, when the promoters of this class of enterprise make the statement that certain profits are assured, that they belong to either one of the two classes that are, perhaps, more the bane of mining than of any other industry—honest fools or knaves. It is little satisfaction to lose money with either.

But it is an unfortunate fact that where large profits are possible, mankind often does not stop to count the chances against their realization. The promotor who is knave enough to promise, or fool enough to believe, that large profits will result from subscribing for the stock of the Easy Mark Mining Co., owner of 1000 acres of promising mining property in Eldorado, and publishes his promise or belief, sounds a note that draws the interested attention of the great majority of that large class with a small surplus to invest. Were the prospectus to state simply that the prospect, in the opinion of some engineer or geologist, promised to disclose a valuable body of ore, but that no one could say what it would be worth, no attention would be given to it. A really fair presentation of a prospect in a prospectus is futile, both because it would fail to secure subscriptions, and because such a presentation would make any price that would be attractive to the promotor manifestly too high. Therefore, the knave, in his presentation, promises the most he can think of, knowing that the people he aims to reach will not check him up, while in the case of trouble, he takes refuge in the allegation that his promises were based on an honest opinion; the fool does not have to *allege* an honest opinion, he really believed all the things he promised.

The fact of the matter is that promotion of companies by public subscription for the development of prospects ought to be prohibited. And yet there is no way in which this can be directly specified, because a prospect is hard to define. But if the law required that all issues offered to the public be underwritten, no such enterprise would ever appear, because no concern satisfactory to the bank commissioner would ever underwrite an issue based on some acreage showing a few iron stains.

The objection that will be raised, no doubt, to this proposal is that mining prospects must be developed or we shall have no mines. This is perfectly true, but let them be developed by people who understand the chances in the business, by small syndicates or mining firms, the members of whom, by close contact with the engineers in charge, can be made to understand the conditions, if they do not already do so. There are plenty of such, and I will venture the opinion that the exclusion from the mining field of the prospect companies fathered by knaves or fools will result in benefit to the industry as a whole, because the money now going into purely chimerical or half-baked schemes will find satisfactory investment in established mining enterprises.

ALLEN H. ROGERS.

Boston, Massachusetts, March 27.

Shaft-Sinking Costs at Pioche

The Editor:

Sir—The record of the costs for sinking the Virginia Louise double-compartment shaft, at Pioche, Nevada, to the depth of one hundred feet, may be of service to your readers. This work was done by four men in 54 days, during which the total number of actual shifts worked was 214. In this district the rate of wages paid by contractors for hand work in sinking dry shafts is \$4 per shift, which is the union scale. Powder in small quantities costs 18c. per pound: Hay costs \$20 per ton, mining timber costs \$42.50 per M, and other supplies in the same proportion. Itemized at these rates the cost of the work is given below:

Labor, 214 shifts at \$4.....	\$856.00
Explosives (300 lb. powder, caps, fuse, thawing) ..	64.70
Expense for horses (hay, shoeing, etc.).....	54.43
Tools (cable, harness, small tools, etc.).....	39.80
One case candles (one-half case left).....	4.25
Hauling tools to the shaft.....	6.00
Sundry expense	2.75

\$1,027.93

To this cost must be added the price of the timbers and hanging rods, for which I have not the actual figures, but which I know to be less than \$4.75 per foot, which makes the total cost of the completed shaft \$15 per foot. This figure, it must be borne in mind, is the contract cost, and not the contract price, which was an entirely different figure.

While this is a low cost and, when compared to the cost of other shafts of the same size, a very good showing, it is not described as illustrating any particularly rapid work. Were the same men to sink this same shaft a second time, working with the better judgment they gained, together with the added experience in working in this rock, they would reduce the cost a quarter, perhaps more. And, again, at \$15 per foot it might compare unfavorably with the work done at another shaft, of the same size, costing \$50 per foot; and as a matter of fact it would compare unfavorably if the \$50 cost represented the best possible effort under the governing conditions, since the \$15 cost is admittedly too high under the local conditions.

The shaft is well timbered with 8 by 8 Oregon pine (Douglas spruce) for the first 25 ft., after which depth the size of the timbers was reduced to 6 by 8 and continued to the 100-ft. mark with this smaller size. There are two compartments, each 4 by 4½ ft. in the clear, one of which is used as a manway, being fitted up with platforms and inclined ladders. The hoisting compartment is lined with 1-in. boards, no cross-head being required to this depth. The opening in the rock required for the timbers was 6½ by 10½ ft., and each foot of shaft produced 5½ tons of broken rock. The formation through which the shaft was sunk was, for the first 30 ft., a cemented gravel, which was followed by a firm but soft shale in which the work continued to the end of the contract. In the 'cement' the ground was broken by driving 'bulldozers,' a simple bar of steel sharpened to a point, in very much the same shape as a lead pencil, and ranging in length from 2 to 4 ft. The holes made by these points were loaded and fired exactly as a drill-hole. After the shale was reached all the drilling was done with churn-drills, except for an occasional plug, which would be put in with a hammer and hand steel.

Hoisting for the first 20 ft. was done with a windlass, after which a 'whip' was used, which for shallow depths is one of the simplest systems of hoisting that can be employed. In this a horse is harnessed and hitched to a cable which, passing over suitable sheaves, is attached to the bucket in the shaft. To hoist the bucket the horse is driven away from the shaft until the bucket reaches the surface; the horse is turned while the bucket is being dumped, and walking back, the bucket is lowered. Knowing that a horse will pull one-tenth of his weight at the rate of 220 ft. per minute easily, it is a simple matter to show that it is impossible for two men to keep him busy until the shaft

reaches a depth of at least 60 ft. It is, however, entirely too dangerous a method of hoisting to use without taking all the precautions which are needed. In framing the timbers all the material was cut with a big 7-ft. cross-cut saw. This saw was also used for all the framing cuts after the timbers were marked. In putting the timbers in the shaft a platform was hung on the last set, and on this platform the men would work. All timbers, tools, and anything heavy was lowered in a bucket attached to a rope which, passing through a block in the tripod, was fastened to a windlass.

TOM McCORMAC.

Pioche, Nevada, April 13.

The Mine-Owners' Liability for Accidents

The Editor:

Sir—Having duly elected to do business under the compensation provisions of the Roseberry law, rather than under the liability in damages provisions based on negligence, what then becomes the status of the mine-owner? What are his duties under the law and his liabilities toward his employees? These questions arise in every inquiring mind and are entitled to specific answer.

The employer has the first say as to which law he will work under. All employees hired after the election of compensation by the employer are presumed to have accepted compensation if they do not then and there give their employer notice in writing that they do not wish to work under compensation. With the employees who were already under a contract of hire at the time of such election of such employer the case is different. Section 7 of the Roseberry law, which governs this relation, is defective. By decision of the Industrial Accident Board, as a majority of that board understands that section, it provides no way whereby the old employee can elect to come under compensation except to continue to work on for thirty days under the law of liability for negligence without giving notice that he does not elect to be under compensation. At the expiration of thirty days he is under compensation and will so remain. If an employee elect not to be under compensation when the employer has elected to be under it, then the difference must be settled between them as other disagreements are adjusted. The employer can operate under both laws if he wishes to, but is not likely to wish to do so.

When both employer and employee are under the compensation provisions of the Roseberry law, and an accident takes place, when, at the time of the accident the injured workman was performing a service "growing out of and incidental to his employment," and while he was "acting in the line of his duty," if the injury was caused by accident and was not the result of a crime and was not caused by the "wilful misconduct" of the employee, then the employer is liable without regard to who was to blame or whether or not anyone was to blame for the accident. First, he will be liable for medical services and surgical appliances up to \$100. He may select the physician who is to attend the injured workman. If the employee is injured so severely as to require the services of a professional nurse he must pay the full wages of the injured man so long as his own physician says that a nurse is needed, and no longer. If the injured person is totally incapacitated for work, but only temporarily so, then he must pay him 65% of his wages, weekly, beginning the eighth day after the injury, until he is able to go to work again. If he is permanently injured, but not totally incapacitated, then the employer must pay him 65% of the difference between what he was able to earn before he was hurt and what, with due diligence, he will probably be able to earn after the injury. If the employee is permanently injured, and so badly hurt as not to be able to work at all any more, then his employer must pay him weekly, the 65% of his wages already referred to until he had drawn what he would have earned had he kept on at work at the wages he had been commanding during the previous year for three years to come, provided that such wages cannot be taken as less than \$1000 nor more than

\$5000. This will last him 230 or 231 weeks. In the event of the accident resulting in the death of the injured workman the employer must pay the three years' wages to his dependents weekly, as wages were paid; that is, the full amount of the wages instead of 65%. If the dead man left no dependents then the employer has only to provide for a funeral at a cost not to exceed \$100.

After an accident has taken place the employer and his injured employee are at liberty to settle compensation claims in any way mutually agreeable to themselves, either by a lump sum payment or in 'chips and whetstones,' but it is anticipated that employers who avail themselves of the limited liability of compensation will carry out the provisions of compensation in good faith with their injured employees and not seek from that vantage ground to drive the hard bargains with them that have so outraged the public sense of justice under ordinary liability insurance as to have driven that form of accident insurance out of continental Europe. Such settlements should not be made without the consent of the Industrial Accident Board, to the end that the interests of society at large may be protected against injured persons becoming public charges through sacrificing rights which, if preserved, would have kept them above the poverty line.

Common experience the world over has shown that controversies seldom grow out of compensation issues. In Great Britain scarcely one claim in 200 has to be heard and determined in any formal manner. The law is so plain and the benefits so certain that, once both parties understand their rights under the law, settlements are easily effected by agreement, wherever both parties want to do what is right. Where they do not there is always trouble. But if a difference does un happily arise, any party in interest may apply to the Industrial Accident Board to investigate, hear, and determine the rights of the parties, and this it will proceed to do as expeditiously and as inexpensively as possible. This board is not a court. It is a board of inquiry and arbitration, all of the members of whom are chosen by the state, and when an employer and his employees elect compensation, in that very act they mutually agree to leave to the Industrial Accident Board the adjustment of all issues in dispute between them regarding such compensation benefits and obligations. The findings of the board as to facts are final, but if it makes a mistake in law, or an award is procured by fraud, or its award is inconsistent with its own findings of fact, the proceedings of the board may be reviewed and set aside by a superior court. If a superior court errs, an appeal will lie from there to the Supreme Court, but it is not expected that there will be much litigation once the law is judicially construed. All statutes have to run that gauntlet.

Wherever compensation for industrial injuries has taken the place of the law of liability in damages for negligence, it has been found necessary to effect settlements of disputes without appealing to the courts for the reason that the expense of conducting court procedures and the delay amounts, in the case of an injured person flat on his back and with little or no money in the house, to a denial of justice. On an average, in California, since 1905, it has required 4 years, 9 and 7/12 months to get a personal injury case through the courts to final judgment, by which time the injured man and his family have suffered all that they could have suffered, whether they received any recompense at all or not for the injury sustained. Even in those countries where such controversies are heard by judges, it is while they sit as arbitrators and not as courts. The main advantages of compensation to the employer are that it safeguards him against heavy verdicts in damages, and he may pay the compensations in weekly instalments, whereas damage judgments have to be paid in lump sums. Also, he is not required to fight his own men at the instance of liability insurance companies that have insured him against the consequences of lawsuits, not accidents. The advantages of compensation to the workmen mainly are that they get their help when it is needed and rarely have to fight for it. It tides them over their period of greatest adversity, and their title to their compensation is untainted by charity.

Their right to it is as good as their right to wages; as good as the right of a soldier to a pension from his country if he left an arm or a leg on a battlefield.

San Francisco, March 25.

A. J. PILLSBURY.

Interest in Mining

The Editor:

Sir—What is the reason for the general public's lessened interest in mining?

While probably many factors enter into it, it appears that the attitude of the Government in making it more difficult for all mining interests to conform to its arbitrary rulings has been one of the main causes. While the laws governing prospecting and locating of mineral claims on forest reserves are specific and sufficient, they, as often construed by some \$75 per month ranger, discourage the average prospector. Again, it is becoming more and more difficult for the prospector to interest capital after he has found something. The Land Office construction of the laws is such that in many instances it is difficult to comply and obtain patent. The Government appears to take the position these days that every locator, whether of an agricultural, coal, or mineral land, is trying to steal something which 100 or 1000 years from now may be worth a million or more to the general public—this without regard to the execution of the laws as now found and construed for many years. This, no doubt, has deterred mining men from branching out and assisting the prospector. Consequently our best men are confining their efforts to patented and proved or partly developed properties. These are becoming scarce. Recently one of the largest mining companies, out of 600 reports on mines, found only two worthy of purchase. It is becoming a serious question what shall be done to revive interest in mining, especially in prospecting and assisting the prospector; for without this the industry must soon cease.

It is to the prospector, who overcomes hardships not equaled in any other business, that the mining industry owes so much. Now there is not one man in the field, where there were 300 ten years ago. Most practical mining men and engineers of large experience will admit that a development company which will pick out a dozen prospects under the advice and judgment of experienced men, and do a certain amount of work on each, eliminating those not worthy of further development, will make more in the long run, with less capital, than when developed mines are purchased. Still, it is one of the hardest things in mining to interest capital in the development of a prospect except in the case of some illegitimate wild-cat the promoter of which has no regard whatever for the merits of the property or for what he states regarding it. Thanks to the action of the postal authorities and to the laws in some of the states, such promotion is becoming more difficult. We can all assist the cause if we will only have a little backbone, and, when asked about a property which we know is a fake, instead of passing it on with the Mexican's shrug of the shoulders and *quien sabe*, fearlessly tell the truth.

A revision of the mining laws along the lines of the recent article by Horace W. Winchell, in the *Mining and Scientific Press* of March 9, 1912, is very much to be desired, especially so in the authorization of appeals from the decisions of the political officers. That abuse of power in this connection should have been allowed to continue without an uprising is remarkable, and certainly no credit to the intelligence of the mining fraternity.

It is not believed that American citizens will take kindly to any system of leasing from the Government. It is inherent in our own people as a race to want to own that in which we are interested. It will be admitted that the West would never have been opened and developed under other conditions. Leasing from the Government, permanently, and the leasing from the individual for a few months or a year, are separate and distinct propositions.

It will not be difficult to place sufficient restrictions around our present or revised laws to properly protect all

interests. We must get together and pull together, if we would reinstate mining in its legitimate place. There is plenty of capital for honest mining enterprises if the capitalists be shown that they have a chance of success equal to that in other lines of industry. In the mining of precious metals competition is practically eliminated, and this should give the industry the preference.

Ely, Nevada, March 23.

ENGINEER.

Agitating and Circulating Solutions

The Editor:

Sir—Under the above caption you figure, in your issue of February 13, a device which is apparently offered as an innovation. It is, as a matter of fact, a rather crude application of a method which I developed some years ago and employed with great success in the agitation of slime in the cyanide process. The system was fully described, with illustrations, in an article published in the *Engineering and Mining Journal*, February 11, 1904, entitled 'Trapezoidal Slime Agitator.' It was so designed as to keep the entire mass of pulp in active movement and to carry large quantities of air deep into the solution by means of the vortex formed where the stream from the pump impinged upon the surface. The vat was shallow and wide at the feed-end, and narrow and deep at the discharge-end. The jet swept the inclined bottom of the vat, and eddies formed on each side continuously carrying the pulp into the central current. The delivery-pipe from the pump was accurately bent into a curve offering a minimum of resistance to the circulating pulp, and the power requirement for circulating a vat containing 20 tons of slime (dry) diluted to about 65% moisture was a trifle less than 2½ hp. The high velocity of impact was also found to assist in flocculating highly aluminous slime, thus facilitating a high recovery of the gold-bearing solution.

As this system was elaborated so far beyond the suggestion thrown out in your article, it seemed to me desirable to again direct attention to its merits. The device is not covered by patent, and was freely offered to the profession. It will be found extremely efficient as an agitator and aerator, and at the same time very economical of power.

COURTENAY DE KALB.

Tucson, Arizona, April 22.

MINING of sulphur in Louisiana is an interesting process. The sulphur deposit, situated near Lake Charles, lies about 440 ft. beneath the surface and is about 100 ft. thick. Beds of quicksand overlying the sulphur render the sinking of shafts impossible, and the sulphur is therefore pumped to the surface. A well is driven through the overlying strata to the sulphur-impregnated beds, in much the same manner as is usual in sinking wells for oil and gas. In each well there are placed four concentric lines of pipe, having diameters ranging from 10 in. to 1 in. Superheated water and hot air are forced down the pipes and the spaces between them to melt the sulphur and to bring it to the surface. The hot water flows down between the two outer pipes, which are respectively 10 in. and 6 in. diameter, and passes into the sulphur-bearing mass, melting the sulphur. The quantity of sulphur melted and the range of action of the water depend on the temperature of the water and on the pressure at which it is supplied. The heavy melted sulphur runs back into the sump around the bottom of the well pipe, which it enters through holes provided for this purpose. Hot compressed air is forced down through the smallest or 1-in. pipe and at the bottom of the well mixes with the melted sulphur and forms an aerated mass sufficiently low in specific gravity to allow the water-pressure to elevate the melted sulphur to the surface, where it is discharged into large rectangular vats, constructed of rough planking. The dimensions of the vats vary somewhat, but they are made as large as 350 by 250 by 40 ft., and some of them are so arranged that railroad trains can pass between them. After the sulphur has cooled and solidified, it is regularly mined.

NEW YORK

TITANIC'S LOSS AFFECTS MARKET.—COPPER PRODUCTION.—AMALGAMATED DOUBLES DIVIDENDS.—REPORTS OF PORPHYRIES.—REINHARDT'S FAILURE.—GENERAL NOTES.

The loss of the *Titanic* caused a backset in the general market in Eastern financial centres. It is somewhat shameful to speak of the one exception in this regard: the prominence given to wireless telegraphy in this occurrence has been widely used as advertising matter to further the huge manipulation that is being carried forward in the various issues of the Marconi wireless companies.

The copper situation remains very interesting. The best authorities are estimating increased output at 150,000,000 lb., but as opposed to this it is argued that this increase in copper production will not catch up with the increasing rate of consumption. This is altogether a question of general business conditions, rather than a question of the factors that are inherent in the copper situation alone. The uses of copper metal have been greatly extended, and a careful analysis of the future is of more importance than comparisons with the past. It is said—though the state-

RAY CONCENTRATOR, FROM TOP OF POWER-HOUSE.

ment must be taken with large grains of salt—that the copper producers have been compelled to act very strenuously to prevent a runaway market in the metal, and that prices could easily have been pushed to much higher levels. It is a little hard to accept this statement without qualification, after the long, dull, lean period which the copper producers have experienced is considered. Though producers have been able to push quotations to higher levels without difficulty, on the other hand there is some danger of curtailing consumption by this very measure. Low prices made for wider uses of the metal, while advanced quotations tend to drive consumers to the use of cheaper substitutes. It is beyond question that the public is beginning to accept higher prices without as much skepticism as ruled 60 or 90 days ago. Perhaps one of the best indications is the tone of the report made by the chairman of the board of the Rio Tinto at its recent meeting. The Rio Tinto is not a mine, it is an institution; a copper producer about which much history has been written, and the only property to which can be applied the famous passage of Macaulay regarding the Church of Rome in his essay on Ranke's History of the Popes. Rio Tinto, like the Church as described by Macaulay, "reaches back into the shadowy ages of antiquity", a producer for many centuries. The chairman spoke in hopeful tones of the campaign as laid out for years to come. The Rio Tinto is now making a large share of its profits from the pyrite and wash-ores used in the manufacture of sulphuric acid. Rio Tinto is remarkable in that it is a mine operated without the heavy expenditures for development that are ordinarily required on this side.

The improved conditions in the copper market are beginning to show in the resumption of dividends, and in increased payments by those properties that did not suspend distributions; and also in increase in value which has

brought quotations up, although the volume of trading has not increased proportionately. After much discussion and rumor by way of stock-market capital, the Amalgamated Copper has doubled its quarterly dividend and is now paying \$1 per quarter, being at the rate of 4%. The shares are still selling very much too high if dividend record is to be considered apart from market action. Amalgamated is a trading issue, as distinguished from an investment issue. North Butte is evidently making strenuous efforts to get back into its former position, and the property is being much discussed in New York and in Boston with reference to its possibilities, and every favorable development is being emphasized. There has been a little 'odd-lot' activity in Anaconda. A good many of the Butte Coalition shareholders, feeling that their holdings in Anaconda were too small to lock up, have liquidated them in the market. Some weeks ago it was rather expected that an early announcement would be made of the taking over of the Shattuck-Arizona by the Phelps-Dodge interests; evidently the deal could not be consummated. It is now reported that the Shattuck will resume individual operation and proceed with the erection of its smelter as was formerly outlined. The Arizona-Morenci Copper Co. is soon to begin development with a view to early production. The company's property lies next to that of the Arizona Copper Co. and the boards of the two companies are largely identical. The development in the Shannon and in the Arizona Copper Co.'s ground has been such that the board now feels that it is justified in proceeding to make a mine. Hitherto work has been confined to prospecting rather than to actual development.

The showing to be made during the coming year by the porphyries is an interesting feature, at the moment, on account of the recent publication of the annual reports by most of them. The report of Ray Consolidated covers nine months of the year 1911, and shows the production of 14,935,000 lb. of copper. Costs are figured at 9½¢. per pound. But, inasmuch as the period covered included the work of tuning up the mill and similar preliminary expense, it is only reasonable to anticipate a much lower cost. The profit for the nine months was \$298,640, though this must not be considered an index to future earnings. The fifth annual report of the Nevada Consolidated covers fifteen months, owing to a change in the fiscal year, consequently the current report cannot be compared with that of the year previous. Copper produced during the fifteen months was 78,541,670 lb., at a cost of 6.97¢. laid down in New York. The report states that during the months of May, June, and July there was handled a large tonnage of exceedingly low-grade ore of a copper content not heretofore considered commercially valuable, the result being that the Nevada Consolidated can estimate a considerably added tonnage in its ore reserves. The company carried forward to surplus \$1,828,782, the total surplus now being \$10,899,142. The Chino Copper Co. has just published a report covering work done during the past eighteen months, showing a tonnage of developed and partly developed ore in excess of 45,000,000 tons. D. C. Jackling, general manager, in his estimate places developed ore at practically 55,000,000 tons, of which 32,000,000 tons can be handled by steam-shovel. This would give to Chino a life of 30 years with the mill handling 5000 tons per day. From this estimate it would appear that Chino is to be one of the important factors in copper production. The report of the Miami Copper Co. does not show the cost of its copper laid down in New York, but estimates its copper cost with the product on board cars at Miami at 5.80¢. per pound. J. Parke Channing, consulting engineer to the company, estimates ore reserves at 18,000,000 tons, but adds that he does not consider the possibilities of the company's ground by any means exhausted. He states that vigorous exploration work will be carried forward during the coming year. The mill tests which are being carried on at the Inspiration Consolidated are said to be satisfactory, and it is rather expected that records in the way of concentration will be broken when the plant gets under way. The Giroux

recently made a contract to furnish a minimum of 900 tons of ore to the Steptoe plant of the Nevada Consolidated. This contract was to become effective the middle of May. Giroux is hedging a little, and it is now doubtful whether shipments will begin before the first of June. The Giroux shareholders are a very patient crowd; they have waited long for the making of a mine, and apparently the end is not yet in sight.

A receiver has been appointed for the Manhattan Securities Co., which has been promoted in mining ventures in and about Elko, Nevada. The subsidiaries of this company are the Elko Realty & Development Co., the Tuscarora-Nevada Mines Co., and the Gardner Crusher Co. The individuals behind the company are bankers and capitalists of New York and vicinity. The mining market in New York suffered something of a setback by the recent failure of J. Thomas Reinhardt. Reinhardt was one of the spectacular promoters of the Porcupine boom, and conducted one or two 'sky-rocket' manipulations. His firm recently opened offices in London and maintained branches in Toronto and Boston. The office was closed without any notice, and the usual string of employees who came down to work found the doors locked on Monday morning.

The large mining interests operating in Mexico with headquarters in New York are more than ever disturbed by reason of the unsettled conditions prevailing, especially as it appears that matters must be worse before they mend.

BOSTON

BOSTON VIEW OF THE COPPER SITUATION.—H. J. STEVENS' DEATH.—COMPANY REPORTS AND THEIR EFFECTS.

The statement has been made recently that there has been an accumulation of about 70,000,000 lb. of copper which has been held back by the refineries in finished and unfinished shape. This claim was given some attention, but has since been denied by a leading copper interest here which says the excess of mine output over refinery during the last eight months cannot amount to more than one-half of that figure. Whatever unrefined copper is carried by the refineries is not considered in the light of excess baggage at all. The refineries during 1911 cleaned up their stocks and when the mines increased production at the end of 1911, following the improvement in the price of the metal, it was decided that normal stocks of unrefined copper should be accumulated again in order to guard against delays and to insure regular deliveries. It is believed in Boston that the copper situation is about as strong fundamentally as it appears superficially. Owing to the organization of the industry, both producers and consumers are working on closer margins of stocks than heretofore. The present metal surplus, whether viewed in a domestic or world-wide sense, is less than enough to supply the demand for 30 days. There seems to be no reason why copper should not hold its gain around the 16c. mark.

Boston learned with great regret of the death of Horace J. Stevens, the publisher of 'Stevens Copper Handbook,' of Houghton, Michigan. Mr. Stevens had not been in good health for several years past, his invalidism at times delaying the publication of his handbook. He visited Boston from time to time and was always a welcome visitor. From the old country editor type he developed into one of the world's best known authorities on copper mining. He not only ably reviewed copper mines, but enriched his work with pithy comments, some of which brought him threats of libel suits and other reprisals. He left his impress on the copper industry and his death leaves a vacancy which will be hard to fill, as he did much to cement the bond of interest between Boston and the Lake country.

Among other things, the porphyries are revolutionizing methods among the copper-mining companies as to publicity. The stockholders of the Nevada Consolidated and Chino companies have recently received very elaborate statements for the period ended December 31, 1911. Along with the statements are photographs of the mines and mills, together with other illustrations, making a graphic and

altogether instructive presentation to the stockholders. One by one the copper companies, new and old, are acquiescing to the public demand for full publicity. All the porphyry directors are warm advocates of that policy. The statements of Chino, Nevada Consolidated, and Ray Consolidated are each for more than a year, the changes being made in order to make the fiscal year the calendar year. The report of Chino brings the company up from the date of starting operations to the last day of 1911. The report of the Ray Con. Co. was for 18 months. Ray Consolidated's report was considered good in Boston. The stock has acted quite slow marketwise, but those conversant with the property readily understand that it is an immense project and one which is being carefully worked out. The company just now is going through the process of carefully swallowing Ray Central—which morsel it recently secured—and until this has been done little in the way of an active market movement can be expected. The total tonnage for the Ray Con. is given at 77,314,470 tons, averaging 2.17% copper. Of this total, 64,700,000 tons are fully developed and the balance only partly developed.

Second only to the Ray Con. report in real interest was the Chino Copper news. Chino partly paid stock was admitted April 22 to trading on the Stock Exchange. The news was given out that the recent issue of new stock by the company was all taken up by stockholders. The report issued by the company covering the period from the date of starting operations to the last day of 1911, was a good one. In that period Chino produced 986,375 lb. copper, for which it received 13.3c. per lb. Since cost of production was slightly under 10c. per lb., which has since been reduced to around 7½c. per lb., the net profit for the company totaled \$131,232. The company now has developed over 54,980,646 tons of ore, averaging 2.24% copper. Of the entire total, almost 60%, or about 32,000,000 tons, can be mined by steam-shovels.

GLOBE, ARIZONA

J. P. CHANNING ON MIAMI CONDITIONS.

J. Parke Channing, vice-president and consulting engineer of the Miami Copper Co., on a visit to the mine, spoke as follows:

"On the 570-ft. level the ore being opened has a copper content fully up to the average for the orebody. I have never estimated more than 50 ft. of ore below this level, but am confident that it will extend much deeper, and when the time comes a cross-cut will be driven from the main shaft on the 720-ft. level. Unexpected ore was found on the 420-ft. or present extraction level. On all the levels above, the northern limit of the orebody has been determined by an approximately east and west fault, but on the 420-ft. level a drift north through this fault has passed through good ore for a distance of 100 ft. The cost of mining for last year, as shown in our annual report, was \$1.21 per ton. It might have been 40c. less if we had desired to mine wastefully and without regard to the safety of the men. The excessive cost was due to the large amount of square-setting and top-slicing. Production is at the rate of not quite 3,000,000 lb. of copper per month. In the concentrator the Deister tables are doing good work, but changes will be made in the crushing machinery. The Hardinge pebble-mills have demonstrated their superiority over the Chilean mills for fine grinding and will probably eventually replace them in all units. It is also probable that the rigid rolls used for the intermediate crushing will be gradually replaced by heavy spring rolls in all units. The Traylor Engineering Co. is building for us a heavy set of spring rolls, 16 by 42 in., but will have a much more massive frame and heavier construction than those now in use. Seven Crocker-Wheeler 150-hp. motors have been ordered, to replace the 100-hp. motors now used in driving the rolls. Hardinge ball-mills have been tried against the rolls, but have not thus far proved equal to them. Their steel consumption is apparently greater than that of the rolls."

RHODESIA

OCEOLA COMPANY.—DISTRICT NOTES.—BWANA M'KUBWA.

Success has attended two or three small Rhodesian flotations of late and elated by the result of the Turquoise deal Salisbury mining men are putting another company before the South American public. This latest venture is termed the Oceola G. M. Co., Ltd., and the claims to be acquired and worked are situated in the Mazoe district of Mashonaland and about three miles from the Jumbo railway station. It is proposed to erect a 3-stamp mill and it is estimated that a profit of £4000 during the first six months will result. The capital of the company is a modest one—£8000. The property has been reported on by three well known Rhodesian mining men, Messrs. Mumford, Epton, and H. Fraser Roche. From their reports it would appear that the property is pegged on old workings from which ore has been mined to a depth of 150 ft. A main shaft has been driven 114 ft., and a drift put in 120 ft. to the west and 190 ft. to the east exposes the vein for the whole of that distance. It is stated that the vein averages 30 dwt. over 12 in. for 140 ft. Messrs. Mumford and Epton estimate that there is 1600 tons of ore above the 114-ft. level, which they state should produce a profit of from £6000 to £7000.

Affairs at Rhodesia cannot be termed exciting at the present moment. The output does not fluctuate greatly and one hears of few new finds. Furthermore, there has been something in the nature almost of a stampede on the part of certain Witwatersrand firms, who a couple of years ago rushed representatives into Mashonaland. The General Mining & Finance Corporation, Messrs. A. Goerz & Co., and Sir Abe Bailey, are retiring from the field and other wealthy and influential Johannesburg and London houses are doing practically nothing in Rhodesia at the present day. As against this it must be recorded that the Consolidated Gold Fields of South Africa has greatly strengthened its grip on the country and by the absorption of the Rhodesian Exploration & Development Co. has become a most powerful factor in Rhodesia, second only to the Chartered company. The progress of development is also a very decided bull point. A little while ago a reliable estimate of ore reserves in the territory prepared by the Rhodesia Chamber of Mines showed that the developed profitable ore in sight amounted to 6,280,908 tons containing gold to the value of £13,019,226, or sufficient to maintain the present output for a period of five and a half years. No mines belonging to small workers are included in this estimate, though properties of this class were responsible for 26% of the output for last year. Discussing these figures at the annual meeting of the Chamber held in Bulawayo the other day, Mr. Mitchell said the figures relating to the industry were such as to show there was going to be no diminution in the activity of the industry. At the same time Mr. Mitchell admitted that an early or marked rise in the gold yield of the territory is not to be expected at the moment, but it is evident that with development now proceeding on all sides, with the prospect of better conditions in the labor market and with the proposed railway extensions the day of increased gold declaration is approaching.

In Northern Rhodesia no remarkable activity is to be observed at the moment of writing. The railway to the Congo frontier was completed long ago, but capital and interest appear to have been carried on beyond it to the much-debated copper fields of Katanga, and but little seems to have been absorbed by British enterprise in Northwestern Rhodesia. However, the Board of Directors of the Bwana M'Kubwa Copper Co. proposes to proceed with the erection at the mine of a plant, capable to begin with treating 200 tons of ore per day. It will take, it is estimated, about 18 months to complete this equipment. It is, however, hoped to have a first unit, of 75 tons per day capacity, at work on high-grade ore before the end of the current year. The Bwana M'Kubwa mine is situated a few miles south of the Congo Free State's southern frontier, and it is famous for the beautiful specimens of malachite it

produces. It, in fact, has been suggested, and not without reason, that it would pay the company better to sell malachite than to produce copper.

LONDON

FLOTATION COMPANIES UNITE.—BROKEN HILL CONCENTRATION.—SAN FRANCISCO DEL ORO AFFAIRS.—OTHER NOTES.

It has been proverbial that the owners of rival flotation processes have been hopelessly irreconcilable when propositions were advanced for the amalgamation of interests and rights and the suspension of legal hostilities. It therefore comes as a surprise to find that the owners of the De Bavay patents on the one part and the owners of the Sulman-Picard-Ballot patents on the other part have buried the hatchet and agreed to a pooling of the royalties as far as Australasia is concerned. The new arrangement does not interfere in any way with the rivalry of the processes from a commercial point of view, and the businesses are not to be amalgamated. Briefly, a new company is to be formed in Australia to collect royalties. The Amalgamated Zinc (De Bavay's) takes 45% of the capital and Minerals Separation 55%. The chief users of the two processes are Amalgamated Zinc on the one hand and the Sulphide Corporation and Zinc Corporation on the other. These three will pay their royalties to the new company. It will be seen therefore that Minerals Separation will receive a profit from the De Bavay work, but on the other hand the De Bavay people will obtain a profit from the work done by the Minerals Separation process at the Sulphide Corporation and the Zinc Corporation. The reason why this settlement was made was that each side admitted that the other had an indisputable right to its particular processes. Minerals Separation had commenced an action against Amalgamated Zinc for infringement of their oil and bubble patents, but, on the other hand, Amalgamated Zinc had the option on the Potter hot-acid patent. Both sides are represented by strong and usually unyielding men, but even they had to admit that the force of circumstances was stronger than that of their own personalities. Hence the settlement. The combined interests are not yet absolutely free from legal trouble, because the appeal by the Elmore's against the Minerals Separations' Australian judgment has not yet been heard by the Judicial Committee of the Privy Council in London. Until this judgment is rendered, I do not consider it advisable to review the flotation position created by the De Bavay-Minerals Separation agreement.

The progress in concentration practice at Broken Hill is well exemplified by the improvements recently introduced by W. E. Wainwright at the Broken Hill South Silver mine. With practically the same tonnage of ore and with no important difference in the amount or quality of the lead concentrate he has been able to increase the output of zinc tailing from 95,990 tons during the first half of 1911 to 123,969 tons during the second half, reducing the worthless tailing from 29,420 tons to 10,571 tons and the troublesome slime from 23,017 tons to 19,911 tons. The value of his work is made more obvious by saying that he now obtains 81½% of the zinc of the original ore in the zinc tailing instead of only 71% six months before. The improvement in this lead-mill may be fully appreciated when we remember that three years ago only 47% of the zinc of the ore was found in the zinc tailing. It is true that the more recent success of the plant is due to the Amalgamated Zinc, the company that treats this zinc tailing to produce the zinc concentrate, accepting a tailing containing a unit less of metal, but the fact that they are willing to do so goes to prove that their process, De Bavay's, is also improving in efficiency.

The troubles at the San Francisco del Oro mine at Parral, Chihuahua, seem never to end. The mine was introduced in England in 1903, and it contains argentiferous sulphides of lead and zinc. At first, the best ore was shipped to smelters, but in 1908 it was decided to erect a concentrating plant that would make it possible to beneficiate a much

larger amount of the ore. The plan was to sell the lead concentrate locally, and to ship the zinc middling to electric smelters in Sweden. The company was reconstructed in 1908 in order to provide the necessary additional capital. Recent reports show that operation has been hindered by the Mexican revolution, by the delay in completing the aerial tramway from the mine to the mill, and by faulty design of the new plant, especially the furnaces for roasting the zinc middling. During the four months, September to December, it was possible to concentrate some low-grade dump material. The aerial tramway has been completed since the end of the year. An interim arrangement has been made with the Cape Copper Co. for the roasting of the zinc middling at Britonferry, South Wales, but there is a prospect of the middling being sold in its raw state to the Swedish smelters in the course of a few months. Percy Tarbutt & Co. have resigned as consulting engineers, and Knox & Allen of New York have been appointed to succeed them. Until H. H. Knox's report on the mine is received, any proposal as to the modification of future policy is postponed.

The report of the Rio Tinto company, operating the premier copper mine of Spain, for 1911, shows a divisible profit of £1,093,939, which compares with £1,045,730 for 1910. The 5% preference shares received £81,250, and the ordinary shares £984,375, being at the rate of 52½%, as compared with 50% in 1910, and 60% in 1909. The average price of copper was £56 ls. 9d. as compared with £57 3s. 2d. in 1910. The extra profit for 1911 was presumably due to the continued increase in the sale of ore for sulphur content. The amount of copper ore mined during the year was 2,185,605 tons, averaging 2.144% copper, an increase of 38,840 tons; of this, 649,215 tons was selected for shipment, and 1,536,390 tons reserved for local treatment by smelting or leaching. The amount exported and invoiced for both copper and sulphur contents was 662,259 tons, as compared with 578,443 tons in 1910. In addition to the copper ore, a large amount of raw ore was exported for sulphur content alone. The report states that the deliveries of sulphur ore, both that which had been leached and the raw ore, totaled 841,964 tons, as compared with 683,505 tons in 1910, and 569,604 tons in 1909. The total copper brought to market as metal and content in pyrite was 33,385 tons. The production of copper at the mines during the year was 21,880 tons, as compared with 22,790 tons in 1910, and 24,364 tons in 1909. The report mentions that the use of machine-drills is being extended, and that the rainfall during the past winter has been excessive, the operations being to some extent hindered by storms and floods. An interesting innovation at the mine is the introduction of underground mining. For years the great open-cuts have been a wonder of the world, and the cost of removing overburden has advanced to the absolute limit. During the last few years millions of dollars have been spent from the reserve fund to make the workings safe. It is an open secret that the mine was threatened with total collapse from this cause. The introduction of mining by adit will therefore bring reassurance to those who were naturally anxious as to the future.

PIOCHE, NEVADA

THIRD INSTALLMENT OF HISTORY OF DISTRICT.—WOOLLEY'S RESIGNATION FROM NEVADA-UTAH.—DIFFICULTIES OF AMALGAMATED PIOCHE.—PRESENT CONDITIONS.

Just before the Day-Bristol Con. M. Co., the Pioche Pacific railroad, and the Mines & Smelters Corporation were launched, the Nevada-Utah, through E. R. Woolley, president, borrowed \$90,000 on short-time notes from L. Vogelstein & Co., New York bankers, closely allied to the United States Metals Refining Co. The three new companies were no sooner formed than Woolley resigned all official connection with any of them, and the larger part of his holdings was transferred to L. Vogelstein & Co., which elected its own board of directors. G. Mead, a New York attorney, succeeded Woolley as president of Nevada-Utah and Amal-

gamated Pioche. The Nevada-Utah no longer held mines in this state, but had become solely a holding company. Entanglements followed rapidly, until all of what had been the Woolley interests became involved in a picturesque variety of snarls. First the notes for \$90,000 became delinquent and the stock holdings of Nevada-Utah in the Consolidated Pioche were sold at auction, only \$990 being realized. For the balance, \$89,010, L. Vogelstein & Co. brought suit in attachment and tied up everything owned here by Nevada-Utah. This closed mine No. 1. No money had been forthcoming to meet the August payroll of the Amalgamated Pioche. Miners' liens had been filed and work continued. When the attachments were levied and No. 1 closed down, a new set of liens was filed. A little later an attorney for the Vogelsteins came and purchased from the holders the first set of liens, but did not take up the second set.

Soon after Mr. Woolley was elected president of Nevada-Utah and Consolidated Pioche, a bond issue of \$500,000 was authorized. The bonds were not issued, but *ad interim* receipts for these bonds were hypothecated at a nominal figure. One of the first official acts of Mr. Mead was to publish a notice repudiating these receipts as being issued without authority. A Salt Lake bank had loaned the \$25,000 required to pay the cash to the Godbes in their Ohio Kentucky stock transaction. This was not paid, and the Salt Lake bank brought suit to recover that, also involving the Nevada-Utah. Default was made on the note for \$125,000 and suit brought to restrain the sale of the securities put up as collateral for that note. Also, as a further precaution, a receiver was asked and Herman E. Freudenthal was appointed receiver for the Pioche Pacific railroad, which he still operates under the supervision of the court. Woolley was indicted in New York. The Governor of Utah refused to surrender him, alleging that the indictment was a ruse to get him to New York and extort money, which should properly be recovered by civil proceedings. The financial ills of the Nevada-Utah having become hopelessly incurable, a receiver was appointed, and on January 15 of this year that once great company was adjudicated bankrupt in a New York court.

The latest news which comes from that city is to the effect that reorganization plans are nearly completed, that these plans involve a bond issue to be underwritten by strong financial interests, and provide ample money for all needs. The new company will be simply a holding company in Nevada. It will control Amalgamated Pioche, and the railroad, and be heavily interested in the Day-Bristol. Under these plans these companies are all to be financed, and the construction of the tunnel through the Bristol range provided for and immediately put through. At present the Pioche Pacific railroad is meeting its current expenses under the management of the receiver. The Day-Bristol, with W. F. Widdicombe, general superintendent, and James Bent, local superintendent of mining operations, is shipping about 500 tons of ore per week at a profit and paying off old obligations incurred during the Woolley regime. One of the assets of the Prince Consolidated consists of the tailing beds at Bullionville. Up to recently these were not available because no smelting company would purchase them at a profit. But when the International S. & R. Co. came into the market the entire ore situation in this district changed for the better. This company closed a contract with the Prince Consolidated for the tailing. Already from the tailing there has accumulated in the Prince treasury over \$85,000, which is increasing at the rate of over \$1000 per day. This solved the problem of financing the railroad spur to the Prince mine. That is now well advanced in construction. The International smelter has closed contracts with the Prince management for all classes of Prince ore, and the other smelters have shown a change of attitude highly exhilarating. The Godbes expect to be shipping soon from the Prince not less than 300 tons of ore per day. Thus the refuse of the old days has provided for the needs of the new, and from the waste of those days will be produced fortunes far eclipsing the profits of that phenomenal era.

General Mining News

ALASKA

THE INNOKO

Mushers passing through Fort Gibbon reported recently that the first stamp-mill of the Innoko district started operation in March. The mill has a capacity of 10 tons of ore per day.

PRINCE WILLIAM SOUND

Unusually rich ore has been discovered on the Ramsay & Rutherford property, according to a report from Valdez.

THE TANANA

The Tanana Water & Power Co., recently incorporated under the laws of Arizona, with headquarters at Phoenix, has acquired from the Tanana Mines Co., through R. T. Harding, all of its water, water rights, and mineral lands. The company is capitalized at \$7,000,000, in 1,400,000 shares of \$5 par value. The company's holdings are in the Tatlanika district. B. H. Borland is president and J. Lindemann secretary of the new corporation. Webber & Co. have started sluicing on Esther creek. Philip McGuire reports finding many good prospects in the Beaver district.

ARIZONA

COCHISE COUNTY

Outside interests recently purchased the balance of stock, amounting to \$500,000, of the Empire Copper & G. M. Co., in the Cochise district. The present management will be retained, together with the consulting engineers, Ricketts & Banks.

GILA COUNTY

(Special Correspondence.)—W. H. Aldridge, managing director for the Inspiration Con. Copper Co., is at Miami. He states that sinking two 3-compartment, steel-concrete working shafts will be started in the near future, and that contracts will soon be let for the grading and excavation work for the 7500-ton concentrator and the necessary railroads. J. M. Callow, consulting metallurgist to the company, has returned and is supervising the tests that are being conducted in the experimental mill at the Inspiration mine. Representatives of several prominent manufacturers of concentrating machinery are at the mines awaiting the results of tests of their machines. They include A. R. Witley; E. J. O'Connell, representing the Deister company; C. I. Glassbrook, of the Mine & Smelter Supply Co.; and P. H. Craven, representing the Craven slime machine. Emil Deister, formerly of the Deister Concentrator Co., is conducting tests on his new slime-treating machine at the Miami and Old Dominion concentrators.

At the Southwestern Miami churn-drill hole No. 3 has been discontinued at a depth of 780 ft., as the string of tools was lost in the bottom of the hole and could not be recovered on account of caving of the ground. A small force of men is at work repairing the Copper Hill shaft of the Arizona Commercial mine. The work has now progressed to a point below the 300-ft. level.

Globe, April 27.

The Miami Copper Co. will pay an initial quarterly dividend of 50c. per share on May 15 to shareholders of record May 1.

MOHAVE COUNTY

The Tom Reed Jr. M. Co.'s shaft is down 160 ft. and has penetrated a vein of gold ore said to be as rich as the Tom Reed mine ore. D. T. Bently, of the owning company, and W. A. Davis, of the Tom Reed Gold Mines Co., with other stockholders, recently inspected the Tom Reed Jr. mine to plan future development.

On the 180-ft. level of the Oro Plata mine a 5-ft. vein of milling-grade gold ore has been intersected. On the adit-level ore assaying as high as 33% lead, and containing some silver and gold, recently was discovered.

PINAL COUNTY

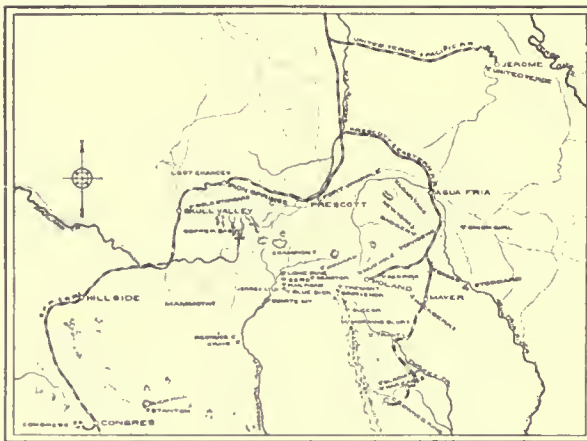

The Magma company has discovered a 4-ft. vein of ore assaying as high as 72% copper and 50 oz. silver per ton, says a press despatch from Florence. James Neary is superintendent of the property.

H. J. Blaise is erecting a 2-stamp prospecting mill at his property, comprising four claims near the Reymert mill. He has a lease on the claims. It is reported that D. C. Jackling is having the Mohawk gold mine examined, and that he and associates may take over that and the Mammoth Collins properties.

YAVAPAI COUNTY

(Special Correspondence.)—The Copper Basin district, about ten miles west of Prescott, is being actively prospected again, owing to the proving of extensive orebodies on the properties of the Commercial M. Co., which is owned by the Phelps-Dodge interests. A railroad survey has been made, and it is said that construction will commence as soon as the contractors on the Verde Valley railroad can complete it and submit bids for the new road.

Darlington & Blickenstaff, of Prescott, have a good prospect in their group of claims in Copper basin. There is

YAVAPAI COUNTY, SHOWING COPPER BASIN.

reason to believe that they have an extension of the Commercial M. Co.'s orebodies. James Douglas, of Douglas; A. J. Pickrell, of the Commercial M. Co., of Prescott; G. E. Tenor, of the Calumet-Arizona M. Co.; and George Kingdom, superintendent of Old Dominion properties at Globe, have been at Jerome making an examination of the Little Daisy property. In the Arkansas & Arizona mine a drift from the 1200-ft. level is cutting a body of copper sulphide. The Verde Valley railroad has laid steel for fourteen miles out of Cedar Glade, and about three miles more will be laid this week. The road will be ready for use into the new smelter town below Jerome about October 1. Prescott, April 29.

A. M. Horton has discovered ore assaying as high as \$1000 per ton, according to newspaper reports, on his Ox Shoe claim in Copper basin. He is erecting a small smelter. A force under L. J. Hohl is prospecting placer ground in the Lynx creek hydraulic district. The Prescott Chamber of Commerce is arranging a permanent exhibit and information bureau regarding mining in the county.

CALIFORNIA

BUTTE COUNTY

The California Extraction Co. is about to construct a concentrator at Oroville for treating dredge-tailing.

Exceptionally rich ore is reported to have been found on the ranch of Mrs. Ida McCallum, on the Oroville-Quincy road, near Berry Creek. The discovery was made by a Swede in Mrs. McCallum's employ. Charles Willett, J. M. Metlung, and John Kincaid have secured a lease on the mine. Water runs within 150 ft. of the discovery and there is plenty of timber nearby, according to reports.

KERN COUNTY

Reports from Randsburg state that Charles Phelps, of

Los Angeles, is planning to organize a company to develop placer claims near the Baltic property at Atolia. A process controlled by the Gold & Platinum Extraction Co. will be used. A small test-mill will be erected at once. A clean-up of 54 tons of ore from the Good Hope mine at the Red Dog mill recently resulted in a \$2900 brick. The Good Hope shaft is now down 220 feet.

LOS ANGELES COUNTY

(Special Correspondence.)—A test run of the Kelley process for the elimination of sulphur from the gases of smelting was made today for the benefit of counsel for the Forest Service, representatives of the Bureau of Mines, and several well known metallurgists. About a ton of ore was smelted in a test lasting for several hours. Careful records of the experiment were made by those present, and while the results of the analyses have not yet been determined, the run showed that the process is not commercially feasible.

Los Angeles, April 30.

MONO COUNTY

A 10-stamp mill and cyanide equipment have been ordered for the Golden Gate mine, in Antelope valley, according to advices from Bridgeport. Hydro-electric power will be used for mine and mill. The property has free-milling gold ore.

SHASTA COUNTY

(Special Correspondence.)—The Farmers' Protective Association has refused to take action on the proposition made by the Balaklala Copper Co. to compensate the grangers for any damage caused by smelter fumes. The company recently offered to set aside an indemnity fund of \$250,000 for reimbursement of farmers suffering damage if the plant at Coram resumed activity. The fund was to be administered by a committee of three, consisting of Judge Morrow, of San Francisco, and representatives of the farmers and the Balaklala company. The refusal of the farmers to act on the offer means its virtual rejection. A movement has been set under way by some farmers to close the Mammoth smelter at Kennett, but opposition of other farmers, living nearer the smelter, promises to defeat the activities of the complainants. McCoy Fitzgerald, president of the association, stated no damage was being done to the vegetation on his farm, which is nearer the smelter than the lands of any other member.

W. E. Vallentine is arranging to develop gravel deposits west of Redding. A cross-cut and drift will be driven. Some of the gravel is said to run 35c. gold per foot. It is rumored the Mountain Copper Co. may install the Thiogen process at Keswick, if the Campo Seco experiments prove satisfactory in every respect. The company maintains shipments of high-grade ore from the Iron Mountain mine to the Martinez smelter, and is receiving some revenue by precipitating copper from the mine waters. In its Hornet mine the company has developed an estimated reserve of 3,000,000 tons. The ore is too low grade to justify its shipment to the Martinez or other distant reduction plants. Despite local rumors, nothing official has been given out.

Redding, April 29.

COLORADO

CLEAR CREEK COUNTY

(Special Correspondence.)—A body of zine 18 in. wide has been uncovered by Farragher & Co. on the Gambetta property. It assays about 54% zine and 35 oz. silver per ton. The Mineral Chief mill has again been brought into commission after an enforced shut-down of three months. A. Swanson & Co., lessees at the Bellevue-Hudson mine, have cut an 8-in. streak of gray copper that assays 750 oz. silver and 3.50 oz. gold per ton. Driving is in progress. Trevillion & Burkholder have a lease on the Champion mine on Covode mountain. Stoping has been started and a 10-in. streak of \$23 ore has been exposed. Seibert & Talley have resumed work upon the O. K. property in Lyon gulch. It is stated that work will soon be resumed on the Gold Fissure property, of which Willis Bristol is manager. The New System mill at Empire was

started up last week and is now treating ore from the Mint mine. It is announced that operation will be resumed during the next 30 days on the property of the Waldorf Con. M. Co., for which C. L. Tingle is manager.

Georgetown, April 25.

GUNNISON COUNTY

It is rumored that the Venture Corporation, of London, has about closed a deal for the Raymond, Gold Links, and other properties in the Ohio district. The report has not been confirmed.

SAN JUAN COUNTY

It is reported that the Pokeepsie M. & R. Co., lessee of the Pokeepsie mine in Poughkeepsie gulch, will resume operation in the near future, and that a power-plant and mill will be erected. H. L. Damsbroder, of Elmore, Ohio, is in Silverton for the company. The Bagley Tunnel Co. is about to commence the construction of a 150-ton Akron mill on its property near Animas Forks, according to a report from Silverton. Charles Gagner is manager for the company. The Telescope Mountain M. & M. Co. is preparing to resume development on its property at Chattanooga. M. A. Norton and H. C. Fisher, both of Colorado Springs, are in charge of the operations. The Ledge Consolidated property, of which Daniel McNaughton is manager, is being unwatered, preparatory to development.

SAN MIGUEL COUNTY

H. Baker, manager for the San Bernardo M. Co., stated recently that he has succeeded in financing the construction of a mill. The Colorado Vanadium Co., for which J. C. Simmons is manager, has purchased the National mill at Sawpit, and will remodel it for treatment of its ore. The Colorado Vanadium property is between Sawpit and Placerville.

TELLER COUNTY (CRIPPLE CREEK)

It is rumored that the El Paso Con. G. M. Co. will announce regular quarterly dividends for the future. The Henry Adney G. M. Co. is cleaning and retimbering the shaft and has several drills operating. The Rex M. & M. Co. has acquired the Iron Clad, Pard, Magna Charta, Quartzite, and Annex claims, all on Globe hill, from the Rex Trading Co. The property formerly was owned by the Cripple Creek Homestake M. & M. Co., which now is defunct. Water has stopped work at the 1335-ft. level of the Cresson Con. G. M. Co.'s main shaft. Hodgins & Johnson, lessees on the Free Coinage G. M. Co.'s property, have intersected an ore-shoot assaying about \$68 per ton. G. W. Davies has acquired by warranty deed from S. L. Duhart the Yosemite group of claims. The Vindicator Con. G. M. Co. on April 25 paid a dividend of 3c. per share. The dividend required the disbursement of \$45,000.

The sump of the Last Dollar shaft is dry. While the shaft is down 1868 ft., water has stood above that level in the Vindicator mine. A plan has been suggested for draining the Vindicator and Golden Cycle shafts by driving a long cross-cut from one of the Portland shafts. At present the Golden Cycle and Vindicator are not benefited by the Roosevelt drainage adit. The Stratton's Independence mill is now treating about 10,000 tons per month of ore averaging about \$3 per ton.

IDAHO

BLAINE COUNTY

The Wilbert M. Co., Ltd., mill, it is reported, was started last Saturday, and soon will be running at full capacity. 150 tons per day. A. S. Ross is president of the company, which owns 15 claims in the Dome district. The property is about 40 miles from Arco.

IDAHO COUNTY

The Last Chance mill is about ready for operation, and the mine is reported to be in good shape for production. The water is unusually late this season, but it is hoped that the Gold Scale placer mine can be started soon.

NEVADA

ESMERALDA COUNTY

The Goldfield Con. Mines Co. has signed a contract with the International S. & R. Co. for the treatment of refractory ore discovered on the 950-ft. and 1000-ft. levels of the Clermont mine three years ago. The ore, which is not suited to the Consolidated mill, assays about $2\frac{1}{2}$ oz. gold, 15 oz. silver, and 4% copper, and occurs in what is believed to be a 'kidney deposit.'

HUMBOLDT COUNTY

(Special Correspondence.)—The cross-cut from the 50-ft. shaft of the Bonanza M. Co.'s property has cut an ore-body said to be 16 ft. wide. The ore contains silver sulphide and some gold. The property, generally known as the Shively, lies five miles north of Winnemucca. D. F. Shively is superintendent. McKenna & Newland recently shipped three tons of silver ore valued at about \$500. Work in a small way has been resumed at the Baldwin group. A cross-cut is being extended from the adit to connect

CLERMONT SHAFT, GOLDFIELD CONSOLIDATED.

with a shaft in which some good silver ore has been opened. The Nevada Superior M. Co. is mining silver ore running over \$200 per ton at Sulphur. The ore is largely from shallow surface workings. J. J. Anderson and James Brown are owners and John W. Geiger is general manager.

Winnemucca, April 26.

LYON COUNTY

(Special Correspondence.)—The Mason Valley Mines Co.'s smelter at Thompson is treating about 700 tons of ore per day. About 350 tons is from the Mason Valley mines, and an almost equal amount from the Nevada Douglas property. Custom copper ore is being received from the Luning, Sodaville, and other districts. Stopping on adit No. 4 at the Mason Valley mines has been suspended, as sufficient ore is available to keep the plant running far beyond its capacity. It is rumored the second furnace of the smelter will probably be blown in before the end of summer. The Nevada Douglas Copper Co. has made the final payment of \$100,000 on the Ludwig mine. It is understood the New Yerington is about to begin shipping. A vein of copper carbonate was recently found at the 225-ft. point. Duncan MacVichie is manager. It is rumored the Bluestone, controlled by Mr. Delamar, may resume operation. It is stated operation will be shortly resumed on the Yerington Malachite. Activity throughout the Yerington and adjoining districts is increasing.

Yerington, April 26.

The New Yerington Copper Co. last week commenced shipping, sending one carload of ore to the smelter. It is said that regular shipments will be made. The Denver No. 2 shaft of the Baltimore M. & M. Co.'s property, Sunrise district, is down 200 ft., and is reported to have cut a 5-ft. vein assaying about \$40 gold per ton. The property includes 19 claims.

NYE COUNTY

The production of the Tonopah district for the week ended April 27 is summarized as follows by the *Tonopah*

Miner: "The Tonopah M. Co. sent 3150 tons, the Belmont Co. 1800 tons, the Montana-Tonopah 1033 tons, the Tonopah Extension 1008 tons, the West End 750 tons, the Mac-Namara 455 tons, and the North Star 40 tons, making the total production for the week 8236 tons of ore, valued at \$205,900."

The report of the Tonopah M. Co. of Nevada for the year ended February 28 includes the following items:

Estimated ore reserves, tons.....	304,824
Ore treated, tons	174,685
Gross value	\$3,503,255
Net earnings of mine and mill.....	1,763,018
Total net surplus	4,680,042
Dividends for the year.....	1,600,000
Total dividends paid to date.....	8,850,000

STOREY COUNTY

The Ophir company last week started a new cross-cut on the 2100-ft. level, and advanced it 17 ft. Its face is in porphyry and seams of quartz. From development on the next level above, 175 tons of ore, averaging about \$15, was saved. During the week 364 tons of second-class ore was shipped to the Kinkead mill. The Mexican mill was operated 55% of the time and crushed 269 tons of ore averaging about \$26, with an apparent extraction of 91%. During development in the Mexican mine there was produced 154 tons of \$29 ore, 105 tons of \$24, and 52 tons of \$21 ore. The Chollar company received, from the lessee of the company's croppings, \$1000 royalty on the March production. The company engaged in the usual development. The Potosi received \$484 royalty from a lessee. The water in the Yellow Jacket mill last Saturday stood $35\frac{1}{2}$ ft. below the 1400-ft. station. The Yellow Jacket mill crushed during the week 472 tons of Crown Point ore. The usual activity marked the other Comstock properties.

WASHOE COUNTY

The Pyramid M. Co. has taken over the holdings of the Pacific Con. Mines Co., which operated for about twenty years in the Pyramid district. Robert W. Parry, manager for the Pacific Con. Mines Co., will be manager for the new owners.

WHITE PINE COUNTY

The Federal Ely company has levied an assessment of 1c. per share, payable May 8. The third boiler at the Ely Consolidated plant is now in place, and the mill is in better condition than it has been for some months.

Reports from Ely state that the United States Tungsten Corporation may resume operation of its holdings. The company was organized by Osear Turner, who obtained an option on the claims from James Butler for the Tonopah M. Co. J. S. Austin, president of the Tonopah company, and J. E. Spurr recently inspected the property. The Tungsten company was in financial difficulty for some time, but it is reported to be in good condition at present.

NEW MEXICO

GRANT COUNTY

The Chino Copper Co. report shows that up to the end of 1911, 2,000,000 cu. yd. of earth had been moved by the steam-shovels. Of this amount about 1,700,000 cu. yd. was waste, the remainder being oxidized copper ore. The average cost of steam-shoveling was 26c. per cubic yard. So far all ore sent to the mill has been oxidized, with correspondingly low recovery. By the middle of the year it is hoped average grade ore can be treated.

SOCORRO COUNTY

(Special Correspondence.)—At the Deadwood Mines in the past week 250 tons of ore was treated, which yielded 2000 lb. concentrate. The mine has been unwatered below the 300-ft. level and a new orebody has been opened on the 200-ft. level. Some of the best grade ore yet found in the Socorro mine is being taken from the bottom of the vertical shaft at a depth of 760 ft. During the week 670 tons of ore was milled by the Ernestine M. Co., with 57 sacks of concentrate. The lower tonnage was caused by mill repairs. The Pacific adit of the Oaks Co., 450 ft.

from the portal, passed through the oxidized zone into sulphide ore. Thirty-five tons was sent to the Deadwood mill from the week's development.

Mogollon, April 26.

UTAH

GRAND COUNTY

The Utah Rare Metals Co., according to an announcement by W. B. G. Chadwick of Telluride, Colorado, will start shipping vanadium ore from its property near Ciseo on May 10. The property is in the Castleton district.

JUAB COUNTY

William Werret and H. T. Orton purchased the McIntyre mill dump ore from the Mammoth M. Co., and are having it treated at the Tooele smelter. It is reported that the price was 75c. per ton, and that some of the ore assays as high as \$10 per ton. The vein of copper ore recently found on the 100-ft. level of the Opohongo has narrowed, but is still furnishing a fair amount of ore. Samuel Cox is superintendent of the property.

TOOELE COUNTY

Salt Lake City reports state that three construction gangs are grading for the branch line to connect the Ophir district with the St. John station on the San Pedro railroad. The grading is to be completed by June 1, and the laying of the rails will require about 15 days. The Ophir Hill mill, owned by W. A. Clark, now having a capacity of 150 tons of ore per day, is to be enlarged to a capacity of 300 tons per day. It is reported that the plant now has 15,000 tons of concentrate ready for shipment. The Lion Hill Con. M. & M. Co., through having cheap power, is developing new ground. At the end of the Eastside adit an incline is being sunk to intersect the Chloride Point bedding.

CANADA

ONTARIO

(Special Correspondence.)—The Hollinger management reports that the headgear on the main shaft is in place and that the construction of the refinery has been started. In the mill the tube-mills are in place and the stamps have been set. No. 2 vein on the 200-ft. level has developed into a rich orebody. The McIntyre is proceeding with the construction of the mill. Twenty more stamps are being installed at present, and arrangements are being made for the addition of twenty more stamps. The mill returns show that 75% of the content is caught on the amalgamating plates and about all the remainder in the concentrate, the tailing running 40 to 60c. per ton. The fourth gold bar was shipped on Thursday, valued at \$3170, and the fifth bar will be shipped on Tuesday. The cross-cut from No. 5 shaft at the 200-ft. level has cut the vein. The Vipond has commenced placing the machinery in the new mill today. The mill is to be in operation by May 20. The Hollinger Reserve has the shaft down 75 ft. and is installing a Rand C-2 air-compressor with a capacity of 585 cubic feet.

South Porcupine, April 22.

YUKON

(Special Correspondence.)—The consolidation of properties by A. N. C. Treadgold in a new company includes the holdings of the Canadian Klondike M. Co., known as the Boyle Concession, situated in the valley of the Klondike; the Bonanza basin, which joins the lower end of the Boyle Concession and runs thence along the Klondike valley to its confluence with the Yukon river; Last Chance creek, a tributary of Hunker creek; the Hunker Development Co., which includes Hunker creek above Gold Bottom; and the Granville Power Co., situated twenty-five miles up the Klondike river. This consolidation means another large company for the district. At present two dredges are employed on the Boyle Concession, one a 16-cu. ft. Marion, and the other a 7-cu. ft. Marion, both of which have good records. In addition to these dredges two new 16-cu. ft. Marion dredges have been ordered by the new company, with the intention of getting them to work this season. One will be placed on the Boyle Concession and the other on the

Bonanza basin property. The Granville power plant will supply the necessary power for the four dredges and also for pumping water to the benches and hills of Last Chance creek for hydraulicking. It is understood that an auxiliary ditch is to be constructed this year, leading from the main Klondike river to a point on the North Fork of the Klondike slightly above the intake of the present ditch. Steam-shovels and other necessities are now being hauled to the intake of the present ditch. Work will be started as soon as the frost leaves the ground.

The new company is known as the Canadian Klondike Co. Joseph Boyle, formerly president of the Canadian Klondike M. Co., is general manager, and Charles Boyle is resident manager. It is not known here who are interested in the company, nor where it was financed. With its equipment complete the company will be able to handle about 30,000 cu. yd. of gravel per day. The two dredges now in commission will begin work April 12, and will continue until some time in December, or for 240 days. The full equipment will no doubt dredge 6,500,000 cu. yd. per year. Present indications point to an early spring, and no doubt the eight dredges of the Yukon Gold company will get an early start. They are now undergoing the usual spring overhauling and will soon be ready for active work. All thawing plants have been busy for some time preparing the ground. The outlook for a successful season is bright, and this year's gold output should exceed that of last.

Dawson, April 9.

The financial statement of the Yukon Gold Co., submitted to the stockholders with the annual report, for the year ended December 30, 1911, is as follows:

ASSETS

Property and investments (including organization expenses and surveys).....	\$12,163,412.52
Equipment (cost of ditches, dredges, and pipe-lines)	6,495,481.33
Deferred charges (operating expenses, stripping and temporary equipment, applicable to future work).....	559,456.62
Supplies and materials.....	605,063.45
Accounts collectable (including advances to subsidiary companies)	321,985.12
Cash	101,500.11
	<hr/>
	\$20,246,899.15

LIABILITIES

Capital stock	\$17,500,000.00
Guggenheim Exploration	1,798,159.57
Bills and accounts payable.....	127,947.24
Depreciation	434,108.24
*Surplus	386,684.10
	<hr/>
	\$20,246,899.15

*Surplus after dividend December 30.

MEXICO

CHIHUAHUA

(Special Correspondence.)—Operation at La Republica M. Co. property for the quarter-year ended March 31, was as follows: ore milled, 2683 tons; production, \$173,775; operating charges, \$129,560; construction and equipment charges, \$21,691.

Operation was greatly hampered and restricted by insufficient mining labor, and the other handicaps brought about by the revolutionary troubles.

Chihuahua, April 25.

Mexico Petroleum Co., Ltd., of Delaware, and Tampico, Mexico, will pay a quarterly dividend of 1% on common stock on May 24 to shareholders of record April 30.

JALISCO

(Special Correspondence.)—Owing to attacks on trains near Irapuato, Guanajuato, the Mexican Express Co., on April 18, notified its agents not to receive valuables for transportation over the line between Guadalajara and Irapuato. This affects the Amparo M. Co., the Mololoa company, the Espada M. Co., and the Lupita M. Co. The

Amparo company will either forward bars in a special car with its own guard, as was done during the revolution of a year ago, or try the method of sending by steamer to San Francisco.

Guadalajara, April 28.

Among the Copper Mines

COPPER IMPORTS, including ore and manufactures, according to figures of the Bureau of Statistics, Department of Commerce and Labor, for the nine months ended with March, amounted to \$31,500,000, and exports to \$86,000,000, the aggregate movement being \$117,500,000. The growth of copper imports and exports of the United States for decennial periods is shown by the following table:

Fiscal year.	Copper imports. (Millions of dollars.)	Copper exports. (Millions of dollars.)
1882	0.6	0.7
1892	1.1	13.2
1902	25.0	43.8
1912	40.0	110.0

UTAH COPPER'S report for the year ended December 31, 1911, includes the following items:

Net operating profit\$4,501,000
Other income 1,766,995

Total income\$6,268,895
Interest charge 30,966

Balance\$6,237,929
Dividends 4,703,022
Surplus 1,534,907
Previous surplus 3,696,539
Total surplus 5,231,446
Written off 2,500,000
Final surplus 2,731,446

Copper produced, 93,514,419 lb., sold at 12.6463c.; gold produced, 40,202,916 oz., sold at \$20; silver produced, 366,906.96 oz., sold at 53 cents.

RAY CONSOLIDATED, in the period from April 1911, when production was commenced, until the end of the year, produced 14,935,447 lb. copper, which it sold for 13c., with a profit of \$147,545. The cost of production during this period was 10 $\frac{3}{4}$ c. per pound. The company began delivery of concentrate to the new smelter at Hayden on February 12, and for March the cost was, approximately, 9 $\frac{1}{2}$ c. per pound. Had the company been able to have delivered its concentrate to the new smelter at the beginning of production, its cost would have averaged 9.33c. per pound. The results so far have also been attained from an ore considerably below the average grade of the mine. The ore shipped up to the end of the year, 681,000 tons, averaged 1.83% copper. The average grade of the 77,314,470 tons developed is 2.17%. Owing to the comparatively low grade of ore treated, though it is checked closely with the drill-hole results at the points from which it was extracted, and owing to the adjustments always necessary in the starting of a new plant, the recovery was necessarily rather low—63.1%. During the month of February 1912 the recovery had been brought up to over 70% on ore averaging over 1.68% copper. The tonnage treated per unit has also been gradually increased and at times averaged over 1100 tons per day, or at the rate of about 9000 tons for the complete plant of eight units.

"There appears no question whatever about the ability of the property to produce copper at 8c. per pound when running on full tonnage and on a normal grade of ore," says the annual report. "As a matter of fact, if we were now running on a 2% ore and making no greater percentage in recovery than at present and experiencing the same costs per ton that now apply to operation at less than one-half our mill capacity, our costs per pound would be less than 8 $\frac{1}{4}$ cents."

Personal

Professional men are invited to send news of their engagements and travels. Such news is interesting to friends.

A. E. WHEELER is in California.

E. A. AUSTIN is at Iditarod, Alaska.

M. W. KREJCI is in southern California.

G. W. METCALFE has been at Los Angeles.

J. MORGAN CLEMENTS has been in Chicago.

J. E. SPURR was in San Francisco Wednesday.

A. C. VEATCH was in San Francisco last week.

E. H. NUTTER has returned from British Columbia.

E. H. BENJAMIN has gone to Cripple Creek, Colorado.

C. H. MUNRO is in San Francisco on his way to Dawson.

C. H. MACNUTT will arrive in London at the end of May.

GEORGE K. EDLER, of Goldfield, has been in San Francisco.

L. J. PFEFFERBERG has returned from Lincoln, Nebraska.

J. R. FARRELL has been in Tonopah and Goldfield this week.

T. T. READ and F. G. COTTRELL were in Los Angeles this week.

WILLIS LAWRENCE will sail for Kobe, on the *Korea*, May 11.

CHARLES DUCHENAU was in San Francisco this week from Tonopah.

VICTOR VON GROT sailed from New York for London last Saturday.

W. W. MEIN and C. W. MERRILL have returned from Poreupine.

JAMES N. WHITMAN is investigating iron ores on the Pacific Coast.

J. S. WILBUR left for South America by way of New York this week.

A. J. EVELAND was in San Francisco on the way from Arizona to Utah.

J. W. MALCOLMSON left Kansas City for El Tigre, Sonora, last Monday.

E. M. RABB has undergone an operation for appendicitis in St. Luke's hospital, Denver.

W. G. ANDERSON, formerly of Zacatecas, is now with the Goleconda Mining Co., Goleconda, Arizona.

D. L. H. FORBES has been appointed consulting engineer for the Trethewey Silver-Cobalt Mine, Limited.

W. R. INGALLS gave the address at the annual commencement of the Michigan College of Mines, April 18.

FREDERICK G. CLAPP has recently been making geological examinations in Monongalia county, West Virginia.

OLIVER B. FINN is on mining business at Radium, Grand county, Colorado, a station on the new 'Moffat' railroad.

L. D. HUNTOON, BRADLEY STOUTON, and A. H. ELLIOTT have joined in the formation of an engineering firm.

E. M. HAMILTON has returned from Tavihe, Oaxaca, Mexico, and is on his way to England for a vacation of two or three months.

J. F. CALLBREATH is representing the American Mining Congress at Washington and has established a temporary office at 602 Munsey building.

H. B. KAEDING has been visiting the Canal Zone, and is now at New Orleans to purchase a new mill for the Siempre Viva Mining Co. of Nicaragua.

R. P. McLAUGHLIN has opened an office in the Mills building, San Francisco, and will engage in a general consulting practice in mining geology and mining engineering.

BAILEY WILLIS has completed the geological survey from San Carlos de Bariloche, in Argentina, to the Chilean frontier, which he has been making under the auspices of the Argentine government.

LOCAL METAL PRICES

San Francisco May 2.

San Francisco is not a primary market for the common metals except quicksilver. The prices quoted below therefore represent sales of small lots and are not such as an ore-producer could expect to realize. Ore contracts usually call for settlements on the basis of Eastern prices, less freight and treatment charges. The prices quoted are in cents per pound, except in the case of quicksilver, which is quoted in dollars per flask of 75 pounds.

Antimony.....11-11 1/2c	Quicksilver (flask).....41.50
Electrolytic Copper.....16 1/2-16 1/4c	Tin.....47-48 1/2c
Pig Lead.....4.15-5.40c	Speller.....7 1/2-7 1/4c
Zinc dust, 1400 lb. casks, per 100 lb., small lots \$9.50-9.75; large \$7.50-8.50	

METAL PRICES

(By wire from New York.)

NEW YORK, May 2.—Trading in metals has remained quiet in New York the past week, and prices of all the standard metals are steady. Average daily prices in cents per pound, based on wholesale transactions, standard brands, are given below.

Date.	Electrolytic Copper.	Lead.	Spelter.	Silver, per oz.
April 25.....	15.75	4.20	6.73	60 1/2
" 26.....	15.70	4.20	6.73	60 1/2
" 27.....	15.70	4.20	6.73	60 1/2
" 28.....	Sunday.	No market.		
" 29.....	15.70	4.20	6.70	60 1/2
" 30.....	15.70	4.20	6.70	61 1/2
May 1.....	15.70	4.20	6.70	61 1/2

SILVER

Below is given the average New York quotation, in cents per ounce, of fine silver for the months indicated:

	1911.	1912.		1911.	1912.
Jan.	53.81	56.25	July	52.57
Feb.	52.23	59.06	Aug.	52.17
Mch.	52.76	58.37	Sept.	52.43
Apr.	52.32	59.04	Oct.	53.37
May	52.31	Nov.	55.77
June	53.04	Dec.	54.85

COPPER

Daily quotations on copper as published in this column represent average wholesale transactions on the New York market and refer to electrolytic copper. Lake copper commands normally from 1-5 to 1-4c. per lb. more. Below are average monthly quotations in cents per pound:

	1911.	1912.		1911.	1912.
Jan.	12.29	14.09	July	12.47
Feb.	12.26	14.08	Aug.	12.41
Mch.	12.14	14.68	Sept.	12.20
Apr.	12.02	15.75	Oct.	12.19
May	11.99	Nov.	12.61
June	12.39	Dec.	13.55

COPPER SURPLUS

Figures showing the visible supply of copper at the beginning of each month are now widely available. Below are given the amounts, in pounds, known to be available at the first of each of certain months.

	U. S.	European.
January 1910.....	141,766,111	244,961,280
January 1911.....	122,030,195	230,264,280
September ".....	133,441,501	191,215,360
October ".....	140,894,856	191,945,600
November ".....	134,997,642	176,816,640
December ".....	111,785,188	164,151,680
January 1912.....	89,454,695	178,329,920
February ".....	66,280,643	153,820,800
March ".....	62,939,988	141,125,680
April ".....	62,367,557	137,806,000

UNITED STATES PRODUCTION AND CONSUMPTION

(Compiled from reports of the Copper Producers' Association)

	Production.	Domestic deliveries.	Exports.
April, 1911	118,185,223	52,407,650	62,129,599
May	126,962,544	64,543,963	61,078,557
June	124,554,312	61,655,561	71,460,519
July	112,167,934	56,982,582	74,880,658
August	125,493,667	59,935,364	69,885,660
September	115,588,950	57,311,584	50,824,011
October	118,255,442	64,068,656	60,084,349
November	111,876,601	68,039,776	67,049,279
December	122,896,697	65,988,474	79,238,716
Total for 1911....	1,431,938,338	709,611,945	754,932,733
January 1912	119,337,753	62,343,901	80,167,904
February	116,035,809	56,228,368	63,148,096
March	125,694,601	67,847,556	58,779,566

LEAD

Lead is quoted ordinarily in cents per pound or dollars per hundred pounds delivered at St. Louis or New York. The difference is normally 15c. per hundred pounds, and any larger or smaller difference is promptly met by sales. The daily price in New York is published each week in this column. Below are the average quotations by months:

	1911.	1912.		1911.	1912.
Jan.	4.48	4.43	July	4.50
Feb.	4.44	4.03	Aug.	4.50
Mch.	4.39	4.07	Sept.	4.48
Apr.	4.41	4.20	Oct.	4.27
May	4.37	Nov.	4.30
June	4.34	Dec.	4.45

ZINC

Zinc is quoted as spelter, standard Western brands, and based upon St. Louis or New York delivery. While New York quotations, as a matter of convenience, are commonly used, relatively little spelter actually goes to or comes from New York. The bulk is shipped direct from the plants in the Mississippi Valley to manufacturers, due allowance being made for freight. New York daily quotations are published in this column each week. Below are given averages by months:

	1911.	1912.		1911.	1912.
Jan.	5.45	6.42	July	5.70
Feb.	5.52	6.50	Aug.	5.95
Mch.	5.56	6.57	Sept.	5.86
Apr.	5.10	6.63	Oct.	6.10
May	5.35	Nov.	6.38
June	5.50	Dec.	6.30

Zinc-dust is quoted separately, the price being based upon the cost of spelter in Illinois and the cost of preparation. About half the zinc-dust used in the United States is imported through San Francisco. Delivery prices are determined largely by quantities and contracts.

QUICKSILVER

The primary market for quicksilver is San Francisco, California being the largest producer. The price is fixed in the open market, and, as quoted weekly in this column, is that at which moderate quantities are sold. Buyers by the carload can usually obtain a slight reduction, and those wanting but a flask or two must expect to pay a slightly higher price. Average monthly quotations in dollars per flask of 75 lb., are given below:

	1911.	1912.		1911.	1912.
Jan.	44.60	43.75	July	48.00
Feb.	48.40	46.00	Aug.	50.00
Mch.	52.50	46.00	Sept.	47.50
Apr.	50.90	42.25	Oct.	46.12
May	46.50	Nov.	45.50
June	46.50	Dec.	44.50

TIN

New York prices control in the American market for tin, since the metal is almost entirely imported. San Francisco quotations, averaging about 5c. per lb. higher than New York, are quoted weekly in this column. Below are given average monthly New York quotations in cents per pound:

	1911.	1912.		1911.	1912.
Jan.	41.25	42.53	July	42.40
Feb.	41.61	42.96	Aug.	43.32
Mch.	40.16	42.58	Sept.	39.75
Apr.	42.18	43.30	Oct.	41.18
May	43.11	Nov.	43.12
June	44.61	Dec.	41.65

Current Prices For Chemicals

(Corrected monthly by Braun-Knecht-Helmann Co.)

Prices quoted are for ordinary quantities in packages as specified. For round lots lower prices may be expected, while in smaller quantities advanced prices are ordinarily charged. Prices named are subject to fluctuation. Other conditions govern Mexican and foreign business.

Copper Production, Earnings, and Dividends

As Estimated by THOMPSON, TOWLE & CO.

The production, earnings, and dividends of the important copper mines of the United States, Mexico, and Canada in 1912 is estimated by Thompson, Towle & Co. in the table opposite, supplemented by the remarks below:

Amalgamated Copper,⁶ has \$12,500,000 5% notes outstanding, due April 1913. Sold to acquire U. M. S. Co.

Ahmeek, ultimate production 25,000,000 lb. Earned \$17.40 per share in 1911.

Allouez, property should be able to double output in 1912. Outlook promising.

Anaconda Copper,⁷ cost should be materially decreased in 1913 with construction work completed.

Arizona Copper, building new smelter which should make possible increased production and decreased cost.

Boleo Copper, actual figures not available. Cost and production estimated.

Braden Copper, entire 3000-ton mill operating in April. Has \$7,000,000 convertible bonds.

British Columbia, 1911 operations handicapped by coal strike, now settled.

Butte-Ballaklava, production has been intermittent. Company involved in litigation with Anaconda.

Calumet & Hecla, income from Ahmeek and Osceola dividend offset by interest on notes.

Calumet & Arizona, in 1911 merged with Superior & Pittsburgh. Company building \$2,000,000 smelter.

Centennial, conditions underground showing improvement. 1911 cost showed considerable reduction over 1910.

Cerro de Paseo, 1912 production will show considerable increase. The 55,000,000 lb. is rough estimate.

Chino Copper, ores partly mined by steam-shovel. Proposed capacity July 1. Has \$2,500,000 convertible bonds.

Copper Range, company owns all Baltic and Tri-Mountain and one-half Champion.

East Butte, smelter being enlarged. Production 1912 may reach 18,000,000 pounds.

First National, shut down July 1911, owing to smoke trouble. Investigating new method.

Franklin, 1912 production should show large increase. Outlook greatly improved.

Giroux Con.,⁸ production shown does not include any high-grade smelting ore from Alpha mine.

Granby Con.,⁹ operated 1911 for 8 months, owing to coal strike. Operation resumed December 1911.

Greene-Cananea, ultimate capacity 70,000,000 lb. Has cash and copper on hand of about \$4,000,000.

Inspiration Con.,¹⁰ has \$6,000,000 convertible 6% bonds.

Isle Royale, production to be increased to 15,000,000 lb. when additional mill capacity is provided.

Lake Copper, has begun production in limited way, using Baltic mill of Copper Range.

Mason Valley,¹¹ treats own ores and does custom smelting business.

Miami Copper, has \$1,500,000 bonds. Production of 1912 should be close to figure shown.

Mohawk Copper, 1912 operations somewhat improved over 1911.

Nevada Con., operations at mine carried on both by steam-shovel and underground.

North Butte, 1912 may show decreased cost.

Ohio Copper, operated 1911 on half-mill working. With entire plant operating, production 20,000,000 pounds.

Old Dominion, costs now at lowest point in company's history.

Osceola made very creditable showing in 1911. Outlook for 1912 quite favorable.

Phelps-Dodge. The production shown for 1911 includes 10,495,649 lb. from custom ore.

Quincy. 1911 profits \$507,000. Cost 10.62c., including construction.

Ray Con.,¹² production will reach 100,000,000 lb. and possibly more.

Shannon Copper, cost of production decreased to as low as 10½c. for some months.

Shattuck-Arizona, shut down in 1911. Development work only being carried on.

South Utah M. & S., began production September 1910. Has made little money to date. Outlook more favorable.

Superior & Boston,¹³ shipments suspended in summer of 1910.

Superior Copper has acquired additional stamp-mill facilities and will soon increase production.

Tamarack, higher metal market has changed the situation considerably.

Tennessee Copper,¹⁴ total production including custom ore in 1911 was 17,641,982 lb., or 1,000,000 lb. increase over 1910.

Teziutlan Copper M. & S. Co., costs for 1911 would have been lower but for Mexican revolution.

Tuolumne, management estimates production of 1,000,000 lb. per month by spring of 1912.

United Verde, cost not available; 1911 dividends aggregate \$2,250,000. Company is building new smelter.

Utah Copper,¹⁴ was merged with Boston Con. in 1910. Owns 1,000,050 shares of Nevada Consolidated.

Utah Con., produced in 1911 3,311,939 lb. lead. Profit credited against the cost of copper.

U. S. Smelting, copper but small proportion of company's output. Earning principally from gold and silver production. Profit for 1911, after heavy depreciation charge, was \$2,840,412, as compared with \$2,484,318 for 1910.

Wolverine, operations for 1912 should differ but little from 1911.

The explanation of the subscripts on the table opposite is as follows:

¹The production shown for the operating mines is that which should be made in 1912, while in the case of the non-producing mines, low-grade porphyries, etc., the figures shown are based on the reduction plants working to capacity.

²Total stock issued when all outstanding bonds have been converted.

³With present plant, built or contemplated, operating to normal capacity.

⁴Where actual figures were not available estimates have been used.

⁵Production when operating under normal conditions.

⁶*Amalgamated's* income is derived from 3,185,802 shares of Anaconda stock, 100,000 shares of Greene-Cananea, and the entire ownership of the United Metals Selling Co., which owns 43,000 shares of the International Smelting & Refining Co. stock. On April 30, 1911, Amalgamated had nearly \$5,000,000 cash on hand.

⁷*Anaconda's* cost has been steadily decreasing as a result of numerous operating efficiencies effected. The earnings shown include profit on custom ore and from subsidiary companies, the latter estimated at \$350,000 per year. The company has cash and quick assets amounting to from \$24,000,000 to \$25,000,000.

⁸*Giroux Consolidated* has made contract with Nevada Con. for treatment of 900 to 1200 tons of porphyry ore per day, beginning May 1. The production shown is on this basis.

⁹*Granby* management plans treating 2000 tons per day from company's Hidden Creek property, resulting in a production of 20,000,000 to 25,000,000 lb. per year, which ultimately would give Granby 45,000,000 to 50,000,000 lb. per year.

¹⁰*Inspiration*. This company owns properties formerly of Inspiration Copper Co. and Live Oak Development Co. The company purposes erecting 7500-ton concentrator. Production should begin by middle of 1913.

¹¹*Mason Valley*. Estimated earnings are placed at \$2 per share on 14c. to 15c. copper. Increased earnings will be made from additional custom ores treated; \$995,000 convertible 6% bonds issued.

¹²*Ray Consolidated*. Early in 1912 this company took over the Ray Central. Approximately \$1,700,000 by this transaction passed into the Ray Con. treasury, Ray Con. assuming \$1,800,000 of Ray Central's bonds.

¹³*Tennessee*. Earnings shown include profits from acid plant. The company early in 1912 was producing 675 tons of sulphuric acid per day. The company has \$1,350,000 bonds outstanding.

¹⁴*Utah Copper*. By summer of 1912 the company will be in a position to increase production from Bingham Canyon mines to 150,000,000 lb. Under these conditions earnings should be, at 12c. copper, \$5.75 per share; 13c. copper, \$6.85 per share; 14c. copper, \$8 per share; 15c. copper, \$9.20 per

share; 16c. copper, \$10.30 per share; and 17c. copper, \$11.50 per share. Cost should be reduced to 7c. At present Utah receives \$1,500,000 dividends from Nevada Consolidated.

¹⁵Old stock.

¹⁶Figures given are for year ended September 30.

¹⁷Cost after allowing heavy depreciation charge.

¹⁸Cost and production shown are for 1910.

¹⁹Quotations Inspiration Copper stock.

*Cost not representative of the mine, hence if given would be misleading.

ORE RESERVES PORPHYRY MINES

	Tons.	Per cent.	Years' life on plants built or contemplated.
Utah Copper	203,000,000	1.67	29
Ray Consolidated ...	84,000,000	2.20	24
Chino	55,000,000	2.24	31
Inspiration Con.	45,000,000	2.00	17
Nevada Con.	40,000,000	1.70	14
Miami	18,000,000	2.51	17
Braden	12,000,000	2.85	11
Giroux	16,890,000	1.87	40+

†Based on small production of 1200 tons treated per day.

The Tin Market

Straits shipments for the first half of April are cabled as 1257 tons, and for the whole month are estimated at 3600 tons, according to L. Vogelstein & Co. Supplies from other sources will probably not exceed 1000 tons, a total of 4600 tons. Deliveries are likely to exceed this amount by about 4000 tons. If so, the visible supply will on April 30 fall below 12,000 tons, comparing with the visible of previous years as follows:

	Tons.
April 30, 1911.....	14,441
April 30, 1910.....	17,932
April 30, 1909.....	18,825

Should this prediction as to the visible supply on April 30 prove correct, it will be the lowest since October 1907. The country then was in the midst of the panic of that year and the price was only £146 (31¼c.), afterward falling to £115, while the visible supply mounted steadily until, at the end of January 1910, it has reached 23,024 tons; the high-water mark. These figures, therefore, do not represent either the extent or the rapidity of the shrinkage in stocks, which in a little over two years have been more than cut in two. It should be borne in mind also that whereas previous low figures of the visible supply were made after a series of prosperous years, those of 1912 are being made (unless all signs fail) at a time when business is steadily increasing and promises to expand beyond all previous records. Under these circumstances, L. Vogelstein & Co. are quite strongly of the opinion that while the market may be expected to fluctuate in its usual violent and erratic way, its tendency is more likely to be up than down. In fact, very much higher prices would not be surprising, especially if there is an adjustment of contracts on the London Metal Exchange satisfactory to the Syndicate, negotiations to that end being now in progress. The London stock is entirely in the hands of the Syndicate and has shrunk from 5104 tons on January 31 to only half that quantity, at the present time, with likelihood of further depletion owing to the small April Straits shipments.

Dividends

The Bunker Hill & Sullivan M. & C. Co. of Kellogg, Idaho, has paid its one hundred and seventy-fifth dividend, making a total of \$13,491,750 paid to date. Monthly dividends of \$64,500 are paid.

The Daly West Mining Co., of Park City, Utah, paid its regular quarterly dividend of 30c. per share on April 20 to stockholders of record April 10.

The Centennial-Eureka Mining Co. of Eureka, Utah, paid a dividend of \$1.50 per share on April 30.

The Utah Consolidated Mining Co., of Bingham, Utah, has declared a dividend of 50c. per share.

The Success Mining Co., of Wallace, Idaho, paid a dividend of 1c. per share for March.

Company Reports

HOLLINGER GOLD MINES, LTD.

This company is capitalized at \$3,000,000, in 600,000 shares of a par value of \$5 each, and owns gold mines in Tisdale township, Ontario, Canada. In the first annual report, for the year ended December 31, P. A. Robbins, manager for the company, states that in spite of the disastrous fires of May and July, the company is in sound financial condition, and of the stock, 50,000 shares remain in the treasury. The current indebtedness of \$132,866 is covered by funds advanced by the original syndicate, the members of which have arranged to provide \$275,000 additional to complete work now under way. When milling is started the company will have a plant and completed development valued at \$700,000, and ore reserves estimated at \$10,000,000. The fire loss for the year was \$111,815, or more than was spent on development, \$96,573. Cash on hand amounts to \$7867. Ore reserves are estimated at 462,000 tons, with a gold content of \$10,230,000. Development completed January 1 was 3717 ft. No prospecting has been done below the 200-ft. level, but the ore reserve estimate includes ore to a depth of 300 ft. The company owns four claims, No. 13,154, 13,155, 13,156, and 13,157. Development has been limited to a small area on claims 13,155 and 13,156, and surface prospecting to those claims and No. 13,154. The mill, about completed, will have a capacity of 300 tons per day, and the cyanide plant 500 tons per day. The mill, which is to be electrically driven, will employ coarse grinding, stamping in cyanide solution, tube-milling, concentration followed by amalgamation of concentrate, cyanide treatment of both gangue and concentrate residue.

NORTH STAR MINES COMPANY

This company operates the North Star and other mines in the Grass Valley district, Nevada county, California. During the year ended December 31, the gross production of the North Star property was \$1,025,088. Operating expense was \$509,925, and the cost of development \$46,481, leaving a net profit of \$468,681. Disbursements for the purchase of property and for development in the Cincinnati Hill mine amounted to \$58,065, leaving a balance of \$410,616. Interest and dividends on invested funds brought the company's net income for the year to \$452,890, of which \$425,000 was paid in dividends, at the rate of 17% on the capital stock. The North Star ore crushed at the Central mill amounted to 95,401 tons, which yielded an average of \$10.745 at a cost of \$5.345 per ton for operating and \$0.487 for development. The net profit per ton was \$4.913. The lower yield, as against \$13.683 per ton for the previous year, is attributed to the systematic working of the stopes, without special attention to the richer ore. The operating cost, despite more careful sorting in the mine, was reduced 27c. per ton. Of the total production, 77.1% was recovered in the mills by amalgamation and 22.9% in the cyanide plant. During the year 1978 tons of concentrate was produced, which, after fine grinding, was treated by the cyanide process. The tailing from the cyanide plant assayed about 24c. per ton, indicating a total metallurgical loss of about \$23,000 for the year, or 2% of the ore content. The ore in the upper mine (above the 2700-ft. level) has been exhausted and work there has been discontinued. Some ore of fair grade was found on the 5300-ft. level, the deepest in the mine. At the Cincinnati Hill mine, 3119 ft. of exploration work was done, at a cost of \$46,445. The company expended in purchasing outlying claims, \$11,620, and advanced for the equipment and development of the local hydro-electric plant, \$20,000. Early in the year the company secured an option on the Champion group of mines, at Nevada City, about six miles from Grass Valley. The option was subsequently surrendered, and a new one obtained which gives the company until July 2, 1913, to reach a decision as to purchasing the property. In developing this property \$154,701 has so far been expended.

Decisions Relating to Mining

Specially reported for the MINING AND SCIENTIFIC PRESS.

OIL AND GAS LEASE—NOTICE OF FORFEITURE

Where by the terms of an oil and gas lease, 30 days notice of cancellation for non-payment of royalties was required, it was insufficient to give such notice to the former manager of the leasing company, said company having passed into the hands of a receiver. Notice should have been given to the receiver.

Young v. Scott, (Kansas) 119 Pacific, 873. January 6, 1912.

MIXING CLAIMS—EFFECT OF ISSUANCE OF FINAL RECEIPT

The locator of a mining claim and applicant for patent is not required to do annual assessment work after making final proofs under his patent application and the issuance to him of a receiver's receipt in conformity with the statute and rules of the General Land Office. The acceptance and allowance of the final proofs and the issuance of receipts of purchase constitute a segregation of the lands claimed from the public domain, and such lands are no longer subject to entry or location by a person attempting to set up an adverse location for purposes of contest.

Batterton v. Douglas Mining Co., (Idaho) 120 Pacific, 827. December 13, 1911.

SMELTER FUME—MEASURE OF DAMAGE TO CROPS

Where a growing crop had been injured by sulphur fumes and damages were sought by the farmer from the smelting company whose plant had generated the fumes, it was held that the measure of damages is the difference between the value of the crop before and after the injury, at the time and place thereof. If the crop has been injured from time to time throughout the growing season by the fumes, but was not destroyed entirely, the damage to it may be measured under this rule by the difference between the value of the actual crop at that time, less the actual expense of fitting for market that portion of the probable crop which was prevented from maturing by the injury.

United States S. R. & M. Co. v. Sisam, (Utah) 191 Federal, 293. October 21, 1911.

PLACER LOCATIONS—NECESSITY OF A DISCOVERY

In an action to quiet title to a placer claim the plaintiff testified that his prospecting work had been limited to washing two pans of dirt taken from two places on his claim; that he had found gold in each of them; that he had heard that the ground contained gold under a lava flow, but did not know the depth of the lava or whether a gravel channel lay underneath. It was held that this evidence did not indicate a discovery such as would support plaintiff's claim. The test is the discovery of minerals in such quantities and evidence of such a character as would "justify a person of ordinary prudence in the further expenditure of labor and means, with a reasonable prospect of success, in developing a valuable mine."

Garibaldi v. Grillo, (California) 120 Pacific, 425. January 22, 1912.

LODE CLAIMS—CASTING OFF EXCESS GROUND

Where a locator's preliminary notice called for a lode claim 600 ft. wide and 1500 ft. long, but the boundaries marked on the ground gave him 1650 ft. in length, or 150 ft. in excess of what the law allows, the locator was allowed to cast off the excess, and his location was not thereby invalidated. As it did not appear that the adverse locator in this case had seen or acted upon the basis of the description in the senior location notice, the usual rule that stakes and monuments upon the ground will prevail over the calls of a location notice in case of discrepancy, was followed, and the senior locator was allowed to claim accordingly, after casting off the excess.

Cardoner v. Stanley Con. M. & M. Co., (Idaho) 193 Federal, 517. December 8, 1911.

Concentrates

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

TEMPERATURE does not increase uniformly with depth beneath the earth's surface, according to some recent researches by Königsberger, who has proved that the rate of increase is more rapid in the vicinity of ore deposits. Near coal seams he found the temperature increased $1^{\circ}\text{C}.$ for each 26 to 30 metres of depth, while near petroleum it rises $1^{\circ}\text{C}.$ for every 8 to 11 m. It has usually been assumed that the average rise is $1^{\circ}\text{C}.$ for every 35 metres.

AN excellent soldering paste which neither spatters nor corrodes is prepared in the following way: Make a mixture of zinc chloride and cheap grease, such as petroleum. Make the zinc chloride by dissolving zinc in strong hydrochloric acid, using an excess of zinc to neutralize all acid. The solution will be thick and oily and is to be mixed thoroughly with the petroleum in the ratio of 1 fl. oz. to 1 lb. This is used extensively in electrical work as a flux for soldering, especially for copper wires, where no acid should be used.

RIPARIAN RIGHTS are not recognized in New Mexico.

Appropriation is made by filing an application with the state engineer before commencing work. Publication of notice of appropriation is required after its approval by the state engineer. One-fifth of the construction work must be completed within one-half of the allotted time, which is commonly five years, and water must be applied usually within four years thereafter. Final certificate issues upon inspection after completion of work. All permits, decrees, and documents regarding water rights must be filed in the office of the probate clerk and *ex-officio* recorder of the county in which the works are situated.

LEAD seldom occurs native in nature, being usually found in the form of a carbonate or sulphide. Metallic lead has, however, been found in the form of thin plates and embedded scales and small rounded globules. Shot-like masses of lead have been commonly found in the gold placers of California, but in such conditions that they have usually been held to be from shot or bullets, and of adventitious origin. Dana lists a number of places, however, at which native lead has been found, and while some are doubtful, others are considered genuine. Ritter Von Griot has recently brought to this country specimens of metallic lead with native gold, found in the Mongolian placers on the Tro river north of Urga. The specimens are small globular masses of lead a millimetre or less in diameter with bits of wire gold showing through the lead. They come from frozen ground 24 ft. under cover and occur with anglesite. There are small veins of galena in the country and the lead is supposed to have been reduced during the process of weathering preceding the formation of the placers.

ELECTRIC BELLS, signaling devices, induction coils, and other apparatus of a like nature is generally actuated by a primary battery, either of the dry or wet type. These batteries, however, require a considerable amount of attention from time to time, and eventually have to be renewed altogether. A small, low-priced transformer which can be connected in the lighting circuit of any alternating-current installation gives much more satisfactory service. The secondary is wound to give 4 or 6 volts. This, being low tension, is suitable for connecting to the usual bell, fire-alarm, or other low-voltage circuit. It completely takes the place of a primary battery, and will operate devices requiring intermittent current. The labor and disorder of recharging batteries is done away with, and the bells operate from year to year without fail. The transformer has no moving parts, is ironclad, enclosed, and entirely safe in use. It is claimed that owing to the small amount of energy used, the average meter will not take any record of it.

BASE MAP OF ILLINOIS. State Geological Survey, F. W. DeWolf, director. Urbana, 1912. This map shows the geographical features, with towns, political boundaries, railways, rivers, and (in red) the elevation of all railway stations. It is on the scale of 1:500,000, approximately 8 miles to the inch. A new and accurate base map of Illinois has long been needed, and Mr. DeWolf has done well to supply this one in advance of completion of the great map for which topographic surveys are now being made.

Commercial Paragraphs

THE OLIVER CONTINUOUS FILTER Co. has six carloads of filters packed at its warehouses ready for immediate shipment to Mexico when conditions permit. One carload of filters had been shipped before the present trouble became acute, and is now at the Mexican border, being held at El Paso.

May 5 to 11 is 'Pocket Smelter Week.' The WAY'S POCKET SMELTER Co., of South Pasadena, California, is offering a valuable cigar lighter, or a copy of the new edition of the 'Prospector's Manual' free to everyone who purchases one of its outfits during this week. In addition to this, the First National Bank of South Pasadena guarantees that every person will get his money back, in the event he should not be fully satisfied with an outfit.

Book Reviews

Any of the books noticed in these columns are for sale by, or can be procured from, the MINING AND SCIENTIFIC PRESS.

TASCHENBUCH FÜR BERGMÄNNER (Pocketbook for Miners). By Hans von Höfer, Sr., and Hans von Höfer, Jr. 2 vol., 1152 pp., ill. Third, enlarged edition. Leoben, 1911. For sale by the *Mining and Scientific Press*. Price \$5.70.

Höfers' Pocketbook is too little known to American mining engineers, who find so much to read in English that there is little incentive to tread the intricacies of the German language. There are several reasons why the effort is worth while, however, the chief being that as a reference book this is far superior to those published in English. Both the senior and junior editors are engineers of experience and have enlisted the aid of a dozen other well known engineers, who have contributed the discussions of special topics, such as boring, shaft-sinking, mining machinery, transportation, ore-dressing, briquetting, coking, surveying, and electricity. Over against the disadvantage that the treatment of these topics is adapted to German conditions and methods of work, may be set the fact that German methods are now adapted to meet conditions that are gradually developing in America, and frequent reference to what has already been done in Germany is of invaluable service in directing American progress. Examples of this are seen in the use of gas-engines and in the briquetting of fuel and ores, as in both cases practice was well developed in Germany before it had received much consideration in the United States. Much of the great store of data included in the volumes is of only academic value to the American engineer, but anyone whose work extends beyond ordinary routine will also find much of value and service.

Catalogues Received

THE HAYWARD Co., 50 Church St., New York. Catalogue No. 39, 'Hayward Buckets.' 40 pages. Illustrated. 6 by 9 inches.

KEYSTONE PLACER DRILL Co., Beaver Falls, Pa. Catalogue No. 6, 'Downie Deep Well Pumps.' 78 pages. Illustrated. 8 by 11 inches.

THE DENVER ENGINEERING WORKS Co. Bulletin No. 1055. 'Improved Richards Pulsator Classifier.' 8 pages. Illustrated. 8 by 11 inches.

THE BROWN HOISTING MACHINERY Co., Cleveland, Ohio. Catalogue D-1912. 'Tramrail Systems, Trolleys, Electric Hoists.' 48 pages. Illustrated. 6 by 9 inches.

ROBINS CONVEYING BELT Co., New York. Bulletin No. 48, 'Chains, Sprockets, and Elevators.' 52 pages. Illustrated. 6 by 9 inches. Bulletin No. 49, 'Conveyor Belts.' 4 pages. Illustrated. 6 by 9 inches.

GENERAL ELECTRIC Co., Schenectady, N. Y. Bulletin No. 4916. 'Mine and Industrial Haulage Supplies.' 328 pages. Illustrated. 8 by 10¾ inches. By means of this catalogue the General Electric Co. places in the hands of its customers information which will enable them to readily select repair parts for the maintenance of locomotives used in mine and industrial electric traction, and of electric crane and hoist equipments. The catalogue includes also a comprehensive list of rail bonds and of materials for the suspension and insulation of trolley and feeder systems. The arrangement of the catalogue is such that from a knowledge of the serial number of a locomotive, any and all repair parts for it may be ordered with accuracy and in a manner to assure prompt filling of orders. While, owing to the much greater variation in conditions for which they have been designed, it has been impractical to catalogue repair parts for crane and hoist equipments in the same manner as for locomotives, all the principal parts for both motors and controlling devices, used in such equipments, will be found listed in appropriate order.

EDITORIAL

SALE of seven million pounds of aluminum in one order for southern California shows that the rise in price of copper has already begun to restrict its use.

THE twenty-fifth annual meeting of the Montana Society of Engineers, held at Anaconda, April 11 to 13, was marked by good-fellowship as well as technical interest. We hope the society may long continue its successful life.

FIRE destroyed, April 20, the plant of the *Mexican Mining Journal*, but the energetic publisher of that excellent exponent of technical journalism promptly arranged for new equipment, and the May number will appear but a few days late. Our sympathy goes to our contemporary. We trust this misfortune may show, as our own of six years ago did, that honest journalism rests on a foundation more substantial than paper and presses, and that disasters have their compensations in the revelation of friendships that they bring.

EXPORTS of copper from the United States have grown during the past thirty years from \$700,000 to \$110,000,000 annually. During the same period imports have grown from \$600,000 to \$25,000,000, representing ore, matte, and blister sent to this country for refining. Though there are only nine electrolytic refineries in operation in the United States, they handle, in addition to domestic blister, over one-third of the copper produced elsewhere in the world. Reports of production for the first quarter of 1912 indicate an increase of about 17 per cent in the United States output and a slight decrease in foreign production.

ELUTRIATION is a word often wrongly used by engineers, under the impression that it is synonymous with classification. To elutriate a material is to purify it by washing; thus bird-shot spilled upon the ground might be swept up and elutriated by stirring with water and pouring off the muddy liquid. To classify a mixture of mineral grains, such as an ore, is to separate them into classes of particles which settle in water at an equal rate; unless the particles have been previously sized no separation of one kind from another is thus possible. A nice observance of such distinctions of meaning will lead to a metaphorical elutriation of ideas.

CO-OPERATIVE studies of mining conditions in Illinois are now being conducted under agreement between the United States Bureau of Mines, the State Geological Survey, and the Department of Mining Engineering of the University of Illinois. These studies are directed to conserving the lives of mine workers and the mineral resources of the state, and involve both field and laboratory investigations. A systematic hygrometric survey of the mines is being made together with studies of the gas in coal, of the dust, explosives, and roofs in the mines, and in fact all the natural mining conditions. The work has the active support of operators, miners, and inspectors, and is much the most comprehensive series of investigations relating to mining ever undertaken by an American state.

LITIGATION over title to the mines of the Pittsburg Silver Peak Gold Mining Company was decided by the Supreme Court of Nevada, May 4, favorably to the Blair estate, from which the operating company derives its rights. The dispute, which has extended over nearly twenty years, arose from an old option which, it was claimed, had never been properly voided. The company now owning the mines having proved them of value, the inevitable litigation followed. At present a profit of roughly \$360,000 per year is being earned. The property and improvements have been paid for out of earnings, and a surplus has been accumulated, but, pending the decision as to title, no dividends have been paid. Dealings in the stock heretofore have been largely speculative, and in anticipation of a favorable decision the price was run up to \$1.60 this week. While the exact amount of the surplus is not certainly known, it is hardly likely to justify any such price, and quotations have already fallen. The mine is a good one, excellently handled, and, now that uncertainties as to title are out of the way, may be expected to become a regular dividend payer.

EFFORTS are being made at Washington to secure a definite appropriation for the support of investigations by the United States Bureau of Mines in the metal mines of the West. When the work begun by the Geological Survey was transferred to the newly created Bureau of Mines the only funds made available were for the investigation of coal mining. It is a curious fact that exact statistics of accidents in metal mines are not collected except in a few states. Such figures as are available seem to show that loss of life is as great in metal as in coal mining, and a limited inquiry recently conducted by the Bureau of Mines suggests that danger in the metallurgical industries is more common than has been supposed. The health and safety of men in all branches of mining should be the first consideration of those in charge. If needlessly dangerous conditions are being overlooked, sharp attention should be called to them, and an impartial government bureau is the best agency for conducting the necessary investigations. We are glad to see that a start has been made in studying the health conditions of mine workers. In this as in other matters the Bureau will have the cordial support of both operators and men, and Congress may well appropriate the small amount of money necessary to make the work effective.

The Value of Gold

Few topics are provocative of greater discussion and variety of opinion than the question as to the stability of the value of gold. As in most discussions, this is largely due to the use of terms in differing senses, or without a clear conception as to their exact meaning. Elsewhere in this issue Mr. A. J. Pillsbury takes issue with Mr. F. J. Martin in this regard, and in pointing out Mr. Martin's error in asserting that gold has a fixed value, falls into the greater error of supposing that gold can be increased in price by increases in the cost of its production. The price of gold cannot be increased, since gold itself is the standard of prices. The value of gold can and does fluctuate, as is seen by the variation in the prices of other commodities from year to year. Price is worth estimated in money, value is worth estimated in commodities in general. The price of gold in the United States is \$20.67 per ounce, the value of gold to a hungry man in the desert, or on Market street, San Francisco, can be roughly determined from the amount of food and drink, or other desired commodity it will procure. Many overlook this elemental distinction, or in making it rush to the opposite extreme and assume

that all changes in prices can be directly ascribed to changes in the output of gold. Such an assumption is as untrue as the assertion that prices are independent of the production of gold. Commodity prices depend upon the available supply of gold, but the relation is a complex one, and the exact relative importance of the different factors is as yet unknown. Perhaps the best analysis of their relationship is that by Mr. Irving Fisher, who contends that the price level of commodities depends upon the amount of money available, the velocity with which it circulates, the amount of bank deposits and their activity, and the volume of trade. It is interesting to note in this connection that the visible available supply of gold in the banks of the world was \$4,447,005,910 on December 31, 1910, and that the same banks at the same time had notes in circulation amounting to \$5,407,022,935 and loans and discounts amounting to \$20,593,333,483. The international volume of trade in 1911, according to the estimates of the Bureau of Commerce and Labor, was \$35,500,000,000. The increase of commodity prices in recent years has often been greatly exaggerated, through a confusion of ideas; the average increase in the past twenty years has probably been less than 20 per cent, the annual gold production having in the same period increased from about \$119,000,000 to \$466,000,000, or an increase of nearly 300 per cent. The rate of increase of production is now declining, and it is quite possible that the production also will begin to decline in the not far distant future.

Alaska at Washington

Introduction at Washington, with the approval of the Alaskan affairs committee of the American Mining Congress, of bills for the leasing of coal lands and the construction of a government railway, marks a distinct step. It is an open secret that neither Alaskans generally nor the leaders in the American Mining Congress are predisposed toward either a leasing system for the mineral lands or government ownership of railways. Those concerned, however, are practical men. They are seeking a workable method of ending the present intolerable conditions and they recognize the force of public opinion. There can be no doubt that the ruling public opinion of the country is opposed to any more land grants to railways and to reopening the coal lands on the old basis. At the same time, as Mr. Falcon Joslin has forcibly shown, it is foolish to impose conditions that compels such communities as Fairbanks to burn 60,000 to 80,000 cords of wood per year, doubling the fuel bill for its citizens, while valuable coal beds are within easy reach. It should be entirely possible to safeguard every proper public interest without any such extreme result; and it will be possible, when the various persons concerned make a genuine effort to get together in any spirit of fairness. Mr. Joslin, who knows Alaska thoroughly, is opposed to the leasing system, but has stated that he is "not certain that a leasing bill may not be drawn that would be a workable and just law," and the committee of which he is chairman has shown good faith by proposing a leasing bill. Now let others show equally good faith by co-operation in securing the passage of a bill modeled on the one offered. We believe that in changing from fee to leasing system the details of the new law should be modeled as closely as possible to the wording of the old. We wish also to state again our conviction that from the national standpoint revenue should be the smallest consideration. If there is any considerable income from the leasing of the land it should go to the state or territory in which the land is situated. This is especially important in the case of Alaska, where the need of public works is great and the sources of revenue are few. In the resolutions passed at Cordova,

April 3, it will be noted that staking by power of attorney is condemned, and in this Alaskan public opinion coincides with informed public opinion everywhere. Reasonably to reward the man on the ground is one thing, but to permit the excesses that have obtained in the past is another and entirely different one. There are obvious faults in the old laws. These should be corrected and the way kept clear for still other changes as the need arises, but Alaska should be developed, and to accomplish that it is necessary to open the coal and other lands to use, and to build railways. We have already stated our conviction that, there being no sufficient inducement for private capital to enter into railway building there, the United States Government should assume the task. Alaskans have made proper concessions to Eastern public opinion. It is now 'up to the East to make good' by providing the needed legislation.

Porphyry Coppers and Ore Reserves

Reports of a number of the great copper mining companies have recently been distributed. We printed last week a summary statement of the work of the Nevada Consolidated Copper Company for the period ended December 31, as given by Mr. Pope Yeatman, consulting engineer for the company. This week we present a similar summary of Mr. D. C. Jackling's report as general manager for the Utah Copper Company. Reports on the work at Ray and Chino are at hand and abstracts will be printed later. In examining these reports, attention is first attracted to the large scale of work, and second to the low grade of ore now being successfully handled.

In the year ended December 31, 1911, the Utah Copper Company treated 4,680,801 tons of ore having an average copper content of 1.51 per cent. The Nevada Consolidated, in the fifteen months covered by the last report, treated 3,338,242 tons of which the average copper content was 1.80 per cent. The Ray Consolidated Copper Company and the Chino Copper Company only began milling in 1911, and their outputs are accordingly small. At Ray, however, 681,000 tons containing an average of 1.83 per cent copper was handled. Perhaps a better impression of the scale of operations is given by the statements of ore reserves submitted with the annual reports. These are as follows:

Company.	Tons.	Per cent copper.
Utah	301,500,000	1.532
Ray	77,314,470	2.17
Chino	54,970,646	2.24
Nevada	40,083,371	1.66

These figures are not strictly comparable. In the reserve of the Nevada Consolidated, Mr. Yeatman has included only the "profitable ore remaining in reserve." In the case of the Utah Copper Company, Mr. Jackling's figures, the ones quoted, include both developed and partly developed ore. The Ray and Chino estimates also include partly developed ore, though the Ray estimate, it is stated, may be 25 per cent less than the total amount of ore really available. Allowing, however, for all such differences in methods of computation, it still remains true that the totals are impressive. Hardly less impressive is the continued increase in ore reserves, despite the large amount annually sent to the mill. Last year the statement of ore reserves of the Utah Copper Company was as follows: Fully developed, 60,000,000 tons of 2 per cent copper ore, and 92,130,000 tons of 1.6 per cent; partly developed, 51,370,000 tons of 1.4 per cent ore; total fully developed 152,130,000 tons; total fully and partly developed, 203,500,000 tons. For the year 1911 the corresponding statement is: Fully developed, 62,040,000 tons, of 2 per cent ore, 92,130,000 tons of 1.6

per cent, and 75,660,000 tons of 1.30 per cent; partly developed, 71,670,000 tons of 1.28 per cent ore; total fully developed, 229,800,000 tons; total fully and partly developed, 301,500,000 tons. Evidently the increase is mainly due to including as ore reserve material too low in grade to be so rated the preceding year, and the complete blocking of the partly developed ore of the year before; presumably through additional drilling. The higher grade ore in reserve, that containing 1.6 and 2 per cent copper, remains practically as it was the year before. The 51,370,000 tons of 1.4 per cent partly developed ore has become 75,660,000 tons of 1.3 per cent fully developed ore, while 71,670,000 tons of material containing 1.28 per cent copper is rated as partly developed ore. Since the amount of ore partly developed in the steam-shovel stopes remained roughly the same, 22,325,000 tons in 1910 and 26,790,000 in 1911, and underground work in this mine is decreasing, it is evidently the churn-drill that makes the difference. At Ray it is explained that ore defined by drill-holes at intervals of 400 feet is considered partly developed. When additional holes are drilled at distances of 200 feet or less the ore is considered fully developed. It is easy to see that partly developed ore can, on this basis, be quickly defined enough to become fully developed, especially if the standard of copper content be at the same time lowered. Every increase in the price makes it possible to count as ore what was previously waste, but it must not be forgotten that when enormous tonnages are taken into account the time factor becomes important. Before this lowest-grade ore can be mined the price of copper may fall to where there would be no profit in handling it. It is impossible to keep the mine in such shape that the low-grade material may not need to be handled regardless of profit. To put it through the mill may be the cheapest means of disposing of it, once the material has been uncovered, but with a fluctuating price for the metal, and a narrow margin at best, there is always the danger of wearing out equipment without adequate return. Material once 'on the run' in a big copper mill can be made to contribute to operating profit if it contains as little as 0.9 per cent copper, but we are still far from the expected stage when rock containing 1 per cent of copper constitutes an ore reserve, and it is a fair question whether the 1.28 per cent 'partly developed' ore of the Utah Copper Company ought not be further qualified by calling it also 'provisional' ore. The Nevada Consolidated Copper Company in June 1911, treated 294,793 tons of ore containing 1.36 per cent copper, 0.009 oz. gold, and 0.071 oz. silver, with a saving of 66.31 per cent and a ratio of concentration of 12.87. The average price of electrolytic copper in New York that month was 12.47 cents per pound. This, we believe, is the record for large-scale treatment of low-grade ore, and certainly it strongly supports claims for considering, at least provisionally, 1.28 per cent rock as ore.

Another striking feature of modern copper concentration, and one much less encouraging, is the enormous amount of waste. In the case of the two leading properties in the group under review, the amount of copper that gets away yearly amounts now to over 50,000,000 pounds. This is the startling result of milling ore of a grade where low operating cost must always be the first consideration. In our pride at the technical work which has converted mountains of rock into ore, it is worth taking an occasional sobering thought of the unachieved. No one anticipates a time when a perfect saving will be made, and no one is working more earnestly toward improvement of technical processes than are the engineers concerned with copper mining and milling. They have accomplished great tasks and are making excellent progress, but the journey is not yet done.

Presenting Assay Results by Graphic Methods

By J. B. STEWART

Because of his early experience as field engineer, accustomed to report to his superiors in the profession, the average engineer acquires the habit of making a purely technical exposition of tabulated data, and the customary assay plans of a mining property. He is apt to forget that in all important cases one of the greatest uses to which his report may be put is the convincing of comparatively untechnical men, whose duty it may be to decide upon the business merits of the prospective deal. It should not be necessary to re-write a report for submission to such readers. Many engineers have witnessed the confusion of a board of directors or group of prospective stockholders, who for lack of technical knowledge and practical experience, were unable to appreciate even approximately the relative meaning of a mass of tabulated data of widths, distance, tonnage, and assay values.

Let a report be ever so complete in its method of analysis and subject to simple arithmetical demonstration, yet the conclusions will never be as apparent to the untechnical reader as they are to the engineer who did the work. The significance of this deplorable point is appreciated by the engineer (or new manager) who, called upon to give an opinion to owners of an unprofitable property which is still being worked, has to convince them that it is wise to abandon the property, or at least cease further operations. Many an engineer has despaired of ever making it possible for the untechnical and unpractised reader of his report to synthetically reassemble all the tabulated data of his analysis so as to give as clear a mental conception of the existing conditions as he himself has obtained. It is with such an end in view that I offer the following simple, graphical method for demonstrating conclusions regarding assay data.

This scheme for graphically representing the commercial value of the ore in a mine by combining the factors of available tonnage and the corresponding assay value per ton has proved very satisfactory, because of the data which it condenses, and the ease with which the unprofitable portions of ore may be marked out. In addition to such advantages it furthermore serves to bring together on the same sheet much geological data, thus throwing some additional light upon the probable method of mineralization and subsequent alterations; as oxidation, leaching, and enrichment. For the purpose of rendering the whole of this subject interesting and intelligible to those who are not familiar with the methods of obtaining all the data to be condensed in the graphical diagram, it may be well to rehearse briefly what is an old story to engineers. To begin with, this system is intended to apply chiefly to ore deposits of relatively great length and depth as compared with their width; commonly spoken of as veins in distinction from large stockworks, fahl-bands, and lenses. Likewise it offers its greatest advantages in consideration of banded veins, or those in which both the width and value of the ore vary considerably not only at intervals along its length, but also from wall to wall across any given section. In order to accurately fix all data upon the diagram, it is necessary to locate all points of sampling in the mine with reference to some vertical plane, as a shaft, which connects with all levels of the mine, or by simple survey methods to provide for such accuracy. It is customary to sample the entire width of the vein at regular intervals of from 5 to 10 ft. (according to the degree of accuracy required) along the length of the vein. If the valuable minerals were evenly distributed throughout the whole of the gangue, one single sample would be enough, and no diagram would be required. But since it often happens that the mineral content varies greatly at intervals of 10 ft. along the vein, it follows that there is even more reason for the variation of bands of ore in the vein from wall to wall at any given section. Hence the sample to be taken at every 10-ft. interval along the vein

should consist of as many separate samples as there are separate changes of ore. I use the word changes in preference to kinds of ore. For should a vein show apparently the same kind of ore on both the foot and hanging wall with a different streak between, no matter how narrow or wide, each of these bands of ore (on foot and hanging) should be separately sampled, and a note made of their corresponding width. Whether the intervening strip should be sampled depends upon its width and value, as previously shown by several preliminary samples for former work done. If it is known to be worthless, then it will, as a rule, be sufficient to only note the width of it, and take no sample. Again, if its value is seldom very different from the rock on either side of it, and it is comparatively narrow, say less than 4 in., it may be sufficient to only note its width and take no sample. But if the value of such a streak in connection with its width should be of some importance in calculating the average value of ore at that section then it must be sampled also. Imagination will, of course, suggest conditions where a ½-in. streak might be of high enough content to require separate sampling, whereas in other cases a group of two to four bands of ore aggregating 10-in. width might be safely tested all in one sample. The object of the examination is to determine the extent of variation and relative value of each separate band as well as the gross value of the ore. From such data, will be determined the width of ore to be mined, and its resultant value in numerous small blocks.

In addition to the variation in content of different bands of ore at any given section the importance of taking separate samples is apt to become apparent to the man doing that work because of the difference in the degree of hardness of the rock to be mined off. It is only too easy to get large or small-sized samples from a comparatively soft section of rock. But when the next band is hard as flint, the difficulty and the time consumed in taking as much per inch of width from the hard rock as was taken from the soft one adjoining it practically precludes all reliability, and any attempt to take the two varieties in the same sample will prove useless.

It is desirable when measuring the width of each separate sample cut, to locate them all with respect to either the foot or the hanging wall, and preferably always to the same wall if possible. Later on much consideration may be given to the manner in which the good ore tends to follow closer to one wall than another, or perhaps tends to cross over from one wall to the other. For recording such data during examination, the left hand page of the sample book may be ruled off as suggested in Table 1. The right hand page is most conveniently reserved for notes regarding the geological conditions in the immediate vicinity of the sample.

The reason and method for thus gathering the data at hand should now be plain. It is now necessary to consider the calculations based upon the above data as given in Table 1, and provide for tabulating the results as in Table 2. Here, under the head of 'total dollar-inch value,' is the product of the total value per ton (in terms of dollars) of every separate sample by its corresponding width in inches. From this column is to be calculated the maximum width of ore which will average better than the bare cost of putting such ore upon the surface. In this particular case circumstances made it unprofitable to break ore of less than \$5 per ton wherever it could be avoided. Moreover, the minimum width of stope which could be economically worked was 18 inches.

From this it will be plain that in any case where ore of profitable grade, or over, is less than 18 in. wide, it is necessary to average with it enough of the next best ore adjoining it to obtain the greatest width possible (over 18 in.) which will average \$5 per ton or better. If the ratio

of widths, and assay values for the adjoining ore is such as to preclude choosing a working width which will average \$5 per ton, then such portions must be left unmined and hence should not be taken into account in the final estimates widths of ore exceeding \$5 per ton as much additional width of next best ore as will give the maximum width which will just average \$5 per ton. Hence, by trial as many adjacent samples are combined as will give the de-

of the total tonnage of available ore of profitable grade. But since the purpose is to determine the total tonnage of ore available which will average \$5 per ton from which may be eliminated later on, the tonnage corresponding to the higher assay values, it is desirable to combine with all sired result, and bracketed in the manner shown in Table 2, given above. A third sheet for condensing only such data as has thus been bracketed is then prepared as in Table 3. The real need of this third sheet is in order to provide for averaging

lengthindinally along the vein as well as across it, as has just been accomplished in Table 2. If, however, all of the points of sampling have been equidistant there is no need of making this step if the lengths of all ore-shoots are considerable. When their lengths are small then the obvious corrections (for the end samples) would be applied to the sum total of dollar-ton-inches. But it often happens that owing to old stopes or caved ground, certain places corresponding to equidistant points which should be sampled are inaccessible. Hence, both the total width and its corresponding total dollar-inch value for every point sampled must be multiplied by one-half the sum of the distances intervening between it and the next points of sampling on either side, in terms of feet.

This gives the final two columns of Table 3, in which the

this particular case the drifts, east and west, in each level, were practically so straight that there was no need to locate the points of sampling by actual projection. But it will occur to the reader that if such workings were tortuous, a plat of each level could very conveniently be added to the diagram just below the horizontal base line here used for each level. In such a case the points of sampling should be located exactly as they were measured in the mine, following the curves of the drift, and their corresponding projections located upon the horizontal base line as the points from which the successive ordinates are to be erected for each curve in turn. In all such cases the usefulness of the graphical representation would be still further enhanced by noting the actual assay values, as is the usual custom, in conjunction with the plat of the level.

GRAPHICAL PRESENTATION OF VALUE OF AN ORE-SHOOT. TOTAL VALUE = VALUE PER TON × WIDTH IN INCHES.

sum of the factors of width divided by the total length represented gives the real average width of the ore along the vein. And the sum of the factors of dollar-inches divided first by the total length sampled, and then by the total sums of widths gives the correct average value of the ore per ton over that section.

Instead of making one entire section of any whole level, it is customary to make several sections of each level according to the conditions which may govern the future working of such blocks of ore. Eventually all such blocks are to be tabulated with their corresponding tonnages, average assay value per ton, and the products of such assays by the respective tonnage they represent. Thus, the final average assay value and total tonnage are deduced for the whole level, and in like manner for the whole mine. It is the sum total of all this data which the present graphical method condenses, and offers a most simple solution of the problem of blocking out the tonnage of any required grade of ore.

The method of constructing a curve to show these results will be best understood by reference to the diagram given, which is the result of actual data from a recent examination. First, however, it is necessary to remark that in

For convenience, let us adopt the following scales:

Horizontal scale for length along vein	25 ft. = 1 in.
Vertical " " total width of ore	40 in. = 1 in.
" " " stope width	40 in. = 1 in.
" " " total width × total value	200 = 1 in.
" " " " × any special value	200 = 1 in.

This, I trust, makes the method of construction clear. Now, considering the meaning of the total value curve, wherever these two curves intersect the value of ore must necessarily be \$5/T, hence, all areas included between these two curves will be of ore above \$5/T if the area is above the width curve, and of ore below \$5/T if the area lies below the width curve.

From this it must be apparent that, owing to the ratio of the width curve to total value curve, wherever these two curves intersect the value of ore must necessarily be \$5/T, hence, all areas included between these two curves will be of ore above \$5/T if the area is above the width curve, and of ore below \$5/T if the area lies below the width curve.

This feature is the one which most recommends the use of this system of representation. This made clear, all other refinements suggest themselves at once as follows:

The tonnage of any such areas may be deduced by measuring the area between the width curve and the horizontal base line, between the vertical co-ordinates corresponding to the two points of intersection where the width curve crosses the value curve. Since the width curve is to the vertical scale of 40 in.=1 in. and the length along the level is to the horizontal scale of 25 ft.=1 in., any square inch area is equivalent to 25 ft. of ore, 40 in. wide or $25 \times 3\frac{1}{3} = 83.33$ sq. ft. of ore. This area then multiplied by 100 gives the cubic feet of such ore for 50 ft. above and below the area in question. This figure must be divided by the number of cubic feet of ore in place required to make a ton. Too much attention cannot be called to the importance of determining this factor accurately. For a uniformly dense rock of 3.2 sp. gr. would run exactly 10 cu. ft. per ton, yet because of cracks, crevices, and small and large vug-holes, such a rock, throughout any considerable extent of the mine, is more apt to average 12 to 14 cu. ft. in place per ton. But let us assume that this factor should be 12. We then have $\frac{83.33 \times 100}{12} = 694.41$ tons of ore per square inch of

area for a 100-ft. vertical section of the vein. So that for all purposes, allowing for the errors in plotting to scale, the round figure of 700 tons per square inch may be used or mental approximations.

To obtain the average value of the ore in any such area, it is sufficient for all practical purposes, and most convenient to remember that because of the ratio between the width and value curves the following conditions hold true. When the vertical co-ordinates of both curves agree the value of the ore is \$5/T. If the co-ordinate of the value curve is one-fifth of that of the width curve, then the value is \$1/T. If it is four-fifths the value is \$4. If it is twice as high as the co-ordinate of the width curve then the value is \$10 per ton, and so on.

A little consideration of the above suggests how readily the total value curve may be intersected by curves drawn parallel to the total width curve, which will block off the diagram into ore of \$10/T to \$15/T, \$15/T to \$20/T, \$20/T to \$25/T, etc., the \$0/T to \$5/T being already blocked out by the width curve itself. This would be obtained by successively halving the scale to which the width is plotted as 20 in. = 1 in., 10 in. = 1 in., 5 in. = 1 in.

There is one more addition which may be required by way of a refinement. Having blocked off the horizontal cross-sections of all the ore which, according to assay value per ton, it will not be profitable to mine, suppose it is now necessary to eliminate all sections in which, owing to the combined factors of value and narrow width, it will be impractical to mine. The minimum width of stope that it is practical to carry has been assumed as 18 in. Placing a straight-edge in position so that a horizontal line may be drawn for the whole length of the diagram at a height above the base line equal to 18 in., draw this line in pencil, wherever the total width curve passes below it. Now, considering the sections of the line thus drawn, it is only necessary to note whether at any point the total value curve shows co-ordinates of at least twice or more the height of the of the width curve. For, in any such case, the value of the ore being \$10 T. or better, it will pay to break double the width of ore existing, providing that double the width will exceed 18 in. If there are any such conditions the portion of this stope line corresponding to them is to be erased. Whatever is left of the original pencil line is now to be inked in and shows that the ore vertically above and below these sections cannot be mined if the length is considerable, say 15 ft. or over.

GOVERNMENT authorities of German Southwest Africa estimate that the revenue from the diamond industry will amount to £500,000 in the Budget year of 1912. This amount is mainly composed of the export duties, and to a smaller extent of the mine taxes. According to the *Ber-*

liner Tageblatt, the estimates for this year are of special interest, as it had been reckoned that the export duties would be reduced or converted, but the Budget again provides for the imposition of duties of 33 $\frac{1}{3}$ %, which may be assumed as a proof that a sweeping alteration in the duties cannot be counted on for the time being. Having regard to the fact that a number of diamond fields will be worked out this year, and the northern fields cannot be certainly expected to yield production, the Government authorities estimate the output of diamonds at 850,000 carats for this year, as compared with an estimate of 900,000 carats for 1911.

Russian Copper Production in 1911

ST. PETERSBURG CORRESPONDENCE

The report on the 1911 copper production of Russia is now published and shows that during the year the Russian copper industry has developed very satisfactorily and is justifying the hopes based on the returns of preceding years. So far as metallic copper is concerned, these are record figures and point to a not very distant period when, in order to relieve the local market, particularly in the Caucasus, foreign buyers may have to be sought. In other parts of the Empire, however, the situation is such as to preclude any expectation of exports. The districts are too far inland, and in any case their increased production is still unequal to the increasing demand of the country for copper. It can hardly be expected that the Siberian copper fields as known today will ever yield such a surplus of copper as to glut the Russian market to an extent which will make it profitable to incur the cost of carriage to seaboard for export purposes. Should this ever take place it would probably be through the White Sea, possibly St. Petersburg. However, such a contingency is still a long way off. It is not so in the Caucasus, where the demand is not so local and where it may very soon pay to ship copper to foreign countries. Last year the total production of metallic copper reached the level of 1,582,187 poods. This compares with 1,383,456 poods in 1910. This is an increase for the whole country of 21.6 per cent.

The districts in which this copper has been produced, with the respective quantities which they have contributed, are as follows:

District.	1911, poods.	1910, poods.
Ural	809,000	566,000
Caucasus	487,000	471,000
Altai	1,700	3,500
Siberia	228,000	196,000
Works and refineries (presumably re-smelting scrap)	56,000	57,000

Although these figures are given as the actual returns, they are not necessarily exact; in fact, may be far from it. The returns given for the Ural, for example, in this general statement differ materially from those issued a few weeks ago for that area, and it is difficult, indeed, to reconcile these divergent figures. The statistics given above are perhaps more likely to be correct, being issued later. The important point to notice is that the great increases have taken place in the great centres of copper production, and where decreases are noticed, they are only to be found in the Altai neighborhood, which has for long shown signs of weakening, and in the works and refineries probably because the larger works are collecting and re-smelting waste themselves. If this is so, a certain average, which it is quite impossible at present to establish, would have to be deducted for this waste or scrap. The area where most of the increase has taken place is the Ural, where the advance is 43%. The report referred to above for the Urals alone issued some weeks ago shows an increase of only 32.8%. The largest contribution to the total was made by the Bogosloff estate. Another large contribution was made by the Soimakovsky factory. This factory accounts for a very large proportion of the increase in the production, because in 1910 it had not yet started work.

Yukon Gold

By O. B. PERRY

*During the past year the Yukon Gold Co. acquired a number of creek claims, both by outright purchase and by working agreement. The principal purchases are situated on Upper Bonanza and Eldorado, with some few claims in other portions of the district within the limits of the operation. The total which has been added to the property is estimated at 1,930,000 cu. yd., practically all creek gravels suitable for dredging.

Equipment.—The dredging equipment was increased during 1911 by the addition of two 7-cu. ft. dredges, leased from the Guggenheim Exploration Co., which makes a total of nine in all on the company's property. The two new dredges represent the latest improvements in dredge construction and differ from the ones previously employed in that the hull and superstructure are built of steel, instead of wood. The steel hulls have decided advantages in the way of strength and rigidity, and are so designed that the dredges can be taken down and moved without entailing any loss of material. The first of the two new dredges was finished and started operation on September 23 on claim No. 6 Above Discovery on Bonanza; the second dredge, No. 9, was completed and started operating on October 7 on claim No. 7, Eldorado. The total weight involved in the construction was 1340 tons, and over 55,000 rivets were driven in the construction of each dredge.

The thawing plants were increased by the addition of four new boilers of standard type, with their steam lines and accessory equipment. In connection with the hydraulic work, two new pits were opened on King Solomon hill and completely equipped with two independent sluice-lines, pipe-lines, and monitors. This plant is now ready for operation the coming season. At Trail gulch hydraulic equipment was installed during July, and mining was carried on at this point during the remainder of the season.

Operation.—Dredging operations in 1911 were begun approximately three weeks earlier than in 1910. The dredging season for seven dredges averaged 171½ days, as compared with 159 days in 1910. The dredges started on May 6, average date, and closed for the winter on October 23. The early start in May was made possible by the completion of the steam-driven plant of the Northern Light, Power & Coal Co., which enabled the company to purchase power before its own hydro-electric plant was capable of being operated. The dredges handled 4,151,249 cu. yd. during the season and produced \$2,671,845 gross gold. This represents a gain of 27% in gross value recovered. The average value per cubic yard was 64.35c., as compared with 66.18c. last season, showing a slight decrease, owing to the fact that No. 5 dredge was digging largely in worked ground and tailing, which decreased the average grade of the material handled by this dredge as compared with the season before.

The cost increased from 31.09c. per cu. yd. for 1910, average, to 35.43c. for 1911. A number of different factors entered into this increase. The May operation was disproportionately expensive on account of the necessity for thawing some of the ground in April, when the weather was still cold; the repair costs increased somewhat, due to the heavy bedrock encountered by some of the dredges, and the power costs also were higher from purchasing power locally for the early spring and late fall requirements. The principal increase in cost was in the thawing operation, due to the greater percentage of frozen ground met in this season's operation, which had to be thawed by steam, the ratio of frozen ground to cubic yards dredged in 1911 showing an increase of 19.33% over 1910. The cost per cubic yard was higher on account of this increase, although the thawing cost per square yard of bedrock was lower than in 1910 by about 10%. In the dredging cost are included all thawing charges, preliminary stripping

operations, gross gold tax, selling charges, and depreciation.

The extremely dry season affected the dredging operation, causing a scarcity of water for flotation. The length of the operating season was also reduced on this account by approximately three weeks.

Hydraulic Operation.—During the season a total of 2,125,551 cu. yd. of gravel was washed in the hydraulic mines, including the yardage from leased ground, an increase of 19% over the season of 1910. The total gross production was \$434,382. It will be noted that the production shows a decrease as compared with 1910 of over \$300,000. This is accounted for by the fact that the mechanical elevators were not operated during the season of 1911. The elevators were operated on rich creek gravel, and added materially to the gross production for the season of 1910. The reason for discontinuing the elevator operation is that the dredges have been found to do the same work at much less cost; in fact, they are now handling ground successfully which it was not thought possible to mine by this method. On this account the water from the main ditch system was applied altogether on the hill or bench deposits instead of on both bench and creek gravels, as formerly. The hill deposits being much lower grade, the gross production decreased, although the yardage shows a substantial increase.

The hydraulic work has been confined, thus far, largely to the lower-grade deposits on account of the lack of dump room to permit the working of the better portions. The dredges are rapidly mining the creek ground, so that dump room is being provided, and this difficulty, which has arisen from carrying on both operations simultaneously, will soon disappear. The hydraulic mines were handicapped by extremely low water in the latter part of the season. The Yukon, as well as the Alaska interior, suffered from an extremely dry season, and the flow of the creeks and rivers was the lowest that has been known since records have been kept. This resulted in a shortage of water-supply during the months of August and September which cut down the yardage for these months and increased the operating cost. Even with this handicap the hydraulic cost decreased, the figures for 1911 being 15.5c. per cu. yd., which is the lowest that has yet been reached in the operation.

The main ditch system from the Twelvemile river was operated 150½ days, which was 97.1% of the possible time, as compared with 78.8% for 1910. The average daily delivery, measured at the Klondike pipe-line discharge, was 3089 24-hour miner's inches, and the total water delivered was 482,580 miner's inches, as against 459,319 in 1910. From this it appears that while the increase in operating time was 23.3%, the increase in the amount of water delivered was only 5%, which shows the effect of the extreme dryness of the season. The total charge for operation and maintenance for the ditch for 1911 was \$135,710. Of this amount \$11,859 was charged to power-plant operation and \$123,851 to hydraulic operations. No unusual difficulties were encountered in the operation of the system.

General.—It is apparent from the above analysis that the dredging operations showed a gain in yardage and in gross value, and that the hydraulic operation also showed continued improvement. The dredging cost was high for the reasons pointed out above, but this cost will probably be reduced materially in the next and following seasons. With the construction work now complete and the plants on an operating basis, more time can be given to the factors that make up the cost, and the tendency should be downward. The work for next season will be continued along the same lines as last. The management probably will not attempt to start the dredges as early as last season, unless the conditions are more favorable, but the season should be about the same length.

AUSTRIAN mining engineers will hold a decennial congress at Vienna September 16 to 20 of this year and many important papers are expected to be presented.

*Report of operations for the year ended February 1, 1912.

Zinc-Dust Tests

By W. J. SHARWOOD

*The increasing interest in zinc-dust as a precipitant suggests the publication of details of a few tests which have proved of some use in examining and comparing samples. Unfortunately no definite criteria have as yet been established for valuing zinc-dust for precipitating purposes, but the following will serve to give some idea as to the availability of a sample for the cyanide plant. It should be dry and fine; nearly all, say 95%, should pass a 200-mesh sieve (aperture 0.003 in.), while very little, say not over 1 or 2%, should remain on 100 mesh (0.006 in.), and practically none on 50 or 60 mesh. It should not show any signs of caking, or contain lumps which do not break up at once when shaken on a sieve. Generally speaking, an ash-gray color is a more favorable indication than a decidedly blue or whitish cast; but color cannot be taken as a positive criterion. The presence of a little lead, say 2 to 3%, is an advantage. Laboratory tests made with pure zinc, and with equal weights of alloys containing up to 5% lead, in the same state of fine division (filings between 0.006 and 0.003 in.), have invariably shown more rapid and more nearly complete precipitation of gold and of silver in the case of the lead alloys, although the weight of actual zinc present was less. The presence of a little zinc oxide is apparently without detrimental effect, except as diminishing the percentage of active metal. Attempts to remove the oxide by solvents inevitably lead to the dissolving of more or less metallic zinc, and possibly to the destruction of the finest particles. No injurious effect has been traced to the small amount of cadmium usually present, and other impurities are generally negligible in amount. A number of samples which have proved satisfactory in actual use have shown from 85 to over 95% metallic zinc (that is, zinc in the metallic state), most of them over 90 per cent.

Various published analyses have shown metallic zinc ranging from less than 30 up to 92%, zinc oxide from traces to over 50%, and cadmium from traces up to 1.3% in Belgian, and 1 to 2.5% in Silesian samples. A number of analyses from various sources are to be found in Schnabel's 'Metallurgy' under Zinc, Ingalls' 'Metallurgy of Zinc and Cadmium,' and in 'Mineral Industry,' Vol. II, p. 258. Some of these show carbon up to 3 or 4%, and silica or insoluble up to 9 or 10%, but in general very little of either will be found, and only traces of iron or arsenic. A few of these analyses are summarized in the annexed table, together with incomplete determinations of some samples used in gold precipitation.

TYPICAL ANALYSES OF ZINC-DUST¹

	Metallic zinc.	Zinc oxide.	Lead.	Iron, cadmium, carbon, and insoluble.
1. Belgian	91.5	Little	0.5	..
2. Belgian	88.74	6.60	2.5	2.1
3. Belgian	79.16	11.16	1.9	7.2
4. Average Belgian	84.5	9.3	1.6	4.0
5. Silesian	84.5	4.9	4.3	6.2
6. Silesian	88.5	7.4	2.0	..
7. Silesian	88.2	4.0	3.0 (SO ₂ 4.1)
8. American	29.6	57.5	Trace	(Insol. 9.6)
9. American, good quality	96.0
10. European, imported into U. S., good quality	90.9	4.0	2.7	..
11. European, similar, fair quality	85.0	..	2.0	..
12. European, similar, fair quality	94.6	3.7	0.2	(Iron 0.3)
13. Used at Deloro, Canada	3 to 5	..	1.74	..

Various authorities state the specific gravity of zinc as from 6.85 to 7.21, of zinc oxide from 5.6 to 5.78, and zinc carbonate 4.3 to 4.5. Samples of zinc-dust have shown results from 6.82 to about 7.0, while the material itself weighs approximately 2 to 2.5 gm. per cubic centimetre, or about 120 to 155 lb. per cubic foot, depending largely upon the ex-

tent to which it has been shaken down. No connection has been proved between the apparent density and the quality, but at least one 'heavy' sample was found to give unsatisfactory precipitation.

The following serves to illustrate the desirability of avoiding contact with moisture or moist air in the transportation and storage of this material. On a carload of imported zinc-dust used some years ago in Montana the railroad charges were found to be based on a considerably greater weight than was indicated by the weights of the several casks invoiced as originally shipped from Europe. The total weight found by the daily use of the material bore out the railroad figures, and confirmed the suspicion that the discrepancy was due to oxidation from contact with moist air. This was further proved by analyses for oxide and metallic zinc, a sample taken near the staves of one cask showing about 10% more oxide than another from the middle of the mass. In another case, where very bad precipitation was noted, the material from the bottom of one barrel was lumpy and yielded 39% zinc oxide, while a sample from near the top of the next barrel opened contained 13.5 per cent.

Estimation of Lead in Zinc-Dust.—Weigh 10 gm. into a large beaker (400 to 600 c.c.), moisten with water, then add 200 c.c. water and stir well, then 10 c.c.² strong sulphuric acid, stir well and cover. Stand beaker on hot plate and warm to 60 or 70°C.; if action is very slow at the start add a single drop of very dilute platinum chloride solution; stir at intervals. After action becomes slow add 10 c.c. more acid and continue warming until nearly all the zinc has dissolved. Decant the solution upon a filter, wash the residue in beaker two or three times with water, passing washings over the filter.³ Rinse residue back from filter into beaker. Dissolve residue with a little nitric acid,⁴ transfer to a casserole, and rinse beaker into casserole. Add 5 to 6 c.c. strong sulphuric acid and evaporate to dense fumes. Cool, dilute with water, stir well, cool thoroughly, filter, wash well with water containing 5% sulphuric acid.² Dissolve the lead sulphate in hot ammonium acetate solution, and wash filter thoroughly with the same solution. Dilute this solution with hot water (about 80°C.) and titrate the lead with standard ammonium molybdate, using 1% tannin or ferrocyanide solution as outside indicator.

The molybdate is standardized on pure lead foil, treated in the same way as the lead residue from the zinc-dust. If the ferrocyanide titration is substituted for the molybdate method, the same standard solution will serve for both lead and zinc.

Estimation of Zinc Oxide in Zinc-Dust.—Approximate method based on solubility of zinc oxide in ammonium chloride and ammonia. Solution required, 250 c.c. water; 70 gm. ammonium chloride; 150 c.c. strong ammonia water, sp. gr. 0.90.

Method.—Weigh out 1 gm. zinc-dust into a stout test-tube holding 35 to 50 c.c. Use a disc of soft rubber packing $\frac{1}{16}$ in. thick as a cover for the tube, or use thumb as cover while shaking. Add 25 c.c. of the prepared solution, cover tube, and shake well for exactly five minutes. Agitation must be violent enough to insure all lumps being broken up. Throw mixture promptly on a 9 cm. or 11 cm. filter, rinse tube, and wash filter with hot water, receiving in a 200 or 250-c.c. beaker. Dilute filtrate with hot water to about 100 c.c. Add a drop of phenolphthalein indicator, then HCl till about neutral, then 5 c.c. strong hydrochloric acid. Heat to 80°C. and titrate zinc with standard ferrocyanide, using uranium acetate or nitrate as in-

²The use of 25 c.c. of strong hydrochloric acid, in place of 10 c.c. sulphuric acid, gives equally satisfactory results.

³The two filtrates from the lead and lead sulphate contain the iron, cadmium, and zinc; they may be mixed, made up to a definite volume, and these metals determined in suitable aliquot portions.

⁴If any considerable residue (silica, carbon, etc.) remains at this stage after treatment with nitric acid, it may be filtered off, washed thoroughly, and determined. If in this case a white residue remains after washing, it should be treated with hot ammonium acetate solution, and this should be added to the acetate solution obtained later.

*From the Jour. Chem., Met. & Min. Soc. of S. A.

Soc. Ch. Ind., 1897, p. 968; 9, 11, and 12 original; No. 9 to 13 used in cyanide precipitation at various plants.

dicator. Zinc found in solution $\times 1.245$ = zinc oxide in 1 gram.

This method is rapid and gives fairly approximate results, which are closely comparable if constant conditions are maintained in all tests. The results are slightly high, for the reason that metallic zinc is itself slightly soluble in the solvent employed—but there is no known solvent for the oxide which will not also attack the metal. Tests with freshly prepared zinc filings, passed through a 200-mesh sieve, show that the error from this source is negligible if only five minutes' contact is allowed with the above solution. Carbonate of zinc dissolves in the same way as the oxide.

Estimation of Total Zinc.—Dissolve 1 gm. of dust in dilute hydrochloric acid, heating moderately. Make up to 200 or 250 c.c. in an accurate flask, remove 50 c.c. with an accurate pipette. Add 5 c.c. strong hydrochloric acid and about 2 gm. ammonium chloride, dilute to about 200 c.c. with hot water, heat to $80^{\circ}\text{C}.$ and titrate with ferrocyanide. The ferrocyanide solution is standardized on pure metallic zinc, dissolved in hydrochloric acid, and treated as above.

Determination of Metallic Zinc in Zinc-Dust.—Many methods have been worked out, most of which are not altogether satisfactory. Those which depend on measuring the volume of hydrogen evolved by the action of acid are hampered by the slow rate at which zinc-dust dissolves in dilute acid, and by the readiness with which hydrogen diffuses through rubber tubing and leaky connections. A number of the methods proposed are given in Sutton's 'Volumetric Analysis' (10th ed., pp. 382-383).

I. Very good results are obtained by determining (1) total zinc and (2) zinc in the form of oxide, by the methods given above. The difference is assumed to be metallic zinc. This has the advantage of requiring only one standard solution—potassium ferrocyanide—for both titrations.

II. Reduction of chromic acid, by subjecting the zinc-dust to the action of potassium bichromate acidified with sulphuric acid. The bichromate should be present in considerable excess of the calculated amount necessary for the zinc used. The residual chromic acid is determined by titrating an amount equal to that originally taken, and the solution after the zinc has acted, or aliquot parts of each, either:

- (1) by means of KI, titrating the liberated iodine with thiosulphate (Sutton, p. 383); or
- (2) by means of a standardized solution of ferrous sulphate;
- (3) by adding an excess of a standardized solution of ferrous sulphate and completing titration with standard bichromate.

III. Reduction of ferric chloride or sulphate and titration of the ferrous salt obtained by standard permanganate or bichromate. Sutton (p. 383) recommends using 0.5 gm. zinc-dust with 7 gm. of ferric sulphate and titrating one-fifth of the solution with permanganate. Presumably 14 or 15 gm. of ferric alum would answer equally well for this purpose.

IV. The reduction by the zinc-dust of a solution of iodine in potassium iodide has given fair results, but it is only safe to use small quantities, say 0.1 or 0.2 gm., titrating the residual iodine with thiosulphate.

The following are results obtained with a sample of zinc-dust:

Method I:	Per cent.
Total zinc	91.6
Zinc as oxide (and carbonate).....	12.9
Metallic zinc by difference	78.7
Method II:	
Metallic zinc by reduction of bichromate (3)....	79.6
Method III:	
Metallic zinc by reduction of ferric alum.....	77.1

Whatever reduction method is employed for direct determination of the metal, the metallic zinc can be calculated thus:

1 c.c. N/10 standard solution = 0.00327 gm. zinc.

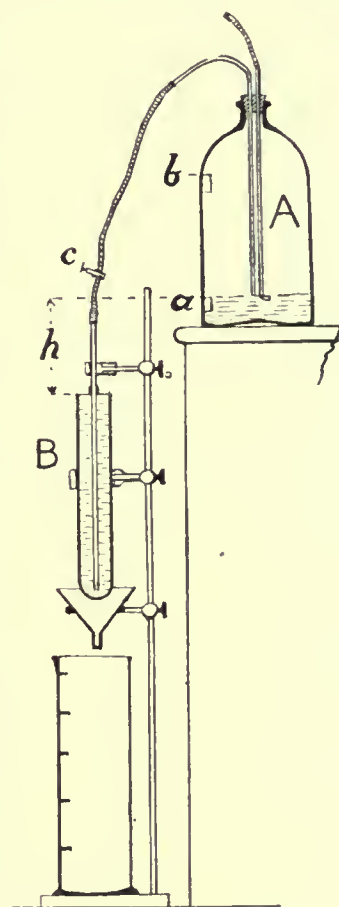

Determination of Precipitating Efficiency of Zinc-Dust.—Solution required. A solution of potassium silver cyanide is prepared by dissolving 10 gm. silver cyanide (AgCN) and 5 gm. of 99% potassium cyanide in a little water and diluting up to 1000 c.c. It is then adjusted by addition of a little more KCN or AgCN until the solution indicates from 0.12 to 0.15% free KCN by titration with standard silver nitrate. The titration is best made by using a 10 or 20-c.c. sample, adding 1 c.c. 2% potassium iodide and a slight excess of ammonia; the end-point is then sharper. Or 15 gm. of pure crystallized $\text{KAg}(\text{CN})_2$ may be dissolved in a litre of water and 1.5 gm. KCN added.

Method: Weigh out 0.5 gm. zinc-dust into a 300-c.c. beaker. Add a few cubic centimetres water and stir till zinc is well mixed, then pour in 250 c.c. of the prepared solution, stirring vigorously. See that all lumps are broken up, and continue stirring for fully five minutes. Stir occasionally (at least every 10 minutes) until the end of two hours from the addition of the solution. Then filter upon an 11-cm. filter, wash precipitate thoroughly, sprinkle with test lead, wrap it carefully in the paper, place in a scorifier with about 20 gm. test lead, burn paper cautiously in muffle, scorify 5 minutes, cupel at low temperature, and weigh silver. Milligrams silver obtained from 0.5 gm. zinc $\times 0.0606$ = percentage precipitating efficiency.

By taking 0.303 gm. zinc-dust instead of 0.5, each milligram of silver is equivalent to 0.1% efficiency. Instead of cupelling, the silver may be dissolved in dilute nitric acid and titrated with standard thiocyanate with ferric indicator, using the whole or one-half of the solution for titration. C.c. N/10 KCNS used for 0.5 gm. $\times 0.654$ = percentage efficiency.

This test was devised by A. J. Clark in 1904, with the idea of utilizing a reaction analogous and taking place under conditions similar to those actually prevailing in the everyday use of the zinc-dust in the cyanide plant. While the results obtained by this method are not entirely satisfactory, they have afforded, during seven years' experience, a better indication of the results to be expected in practical work on the large scale than those obtained by any other system of examination so far tried. Satisfactory samples of dust usually show efficiencies between 40 and 60%, and sometimes as low as 35%, 100% being the standard calculated for the complete replacement of pure zinc by silver. A better method—one which completely eliminates the personal factor in manipulation—is desirable, but a simple determination of the metallic zinc is not sufficient; the test must automatically take into account the physical condition as well. Attempts to carry out the test in a mechanical shaker, and determining the silver left in solution after filtering after a specified time of contact, have always given much lower results than are obtained as above.

Mechanical Tests of Zinc-Dust.—Sizing Test: When sized with sieves of 100 and 200 meshes to the linear inch, using a sample of 20 to 50 gm., good samples of zinc-dust

CLASSIFICATION APPARATUS.

usually show at least 95 and often 98% or more passing the 200-mesh, and not more than 1% remaining on the 100-mesh. This sizing is irrespective of caked lumps, which should never be found in freshly opened barrels.

Classification Test: This is based on the separation of the finest particles by a rising stream of water in a vertical tube, the velocity being about 1 cm. per second. It promises to throw some light on the fineness of division of the portion passing 200-mesh, which, as above indicated, ought to include nearly all of the material.

A convenient arrangement is that shown in the figure. A 2500-c.c. acid bottle (A) is fitted with a 2-hole rubber cork, with a Mariotte tube reaching nearly to the bottom and turned at a right angle at the lower end, and a siphon outlet tube reaching to about the same level, thus giving a constant level water-supply. A mark is placed at *a*, the level to which the siphon empties the bottle, and another at *b* to indicate the surface when 2000 c.c. additional water has been put in. The working cylinder B may be a tall 250-c.c. measuring-glass, but it is better to use a large tube with rounded end, say 1.25 in. diameter by 12 or 15 in. long, with a 1/4-in. glass tube placed centrally in it and connected with the siphon by a rubber tube with a spring clip *c*, both being fastened to a stand by clamps. A large graduated cylinder and funnel are placed below. The net area of the cross-section of the working cylinder is best obtained by sticking two labels or making two marks on it 20 cm. apart, then filling with water to the lower mark and measuring the number of cubic centimetres required to fill it to the upper, the central tube being clamped in place. Then the area of cross-section (= volume in c.c. ÷ height in cm.) is obtained once for all. To adjust the velocity fill the bottle to the upper mark, fill the working cylinder, open spring clip and take time with a stopwatch while 1000 c.c. flows out.

$$\text{Then } \frac{1000 \text{ c.c.}}{\text{Area} \times \text{No. sec.}} = \text{velocity in cm. per second.}$$

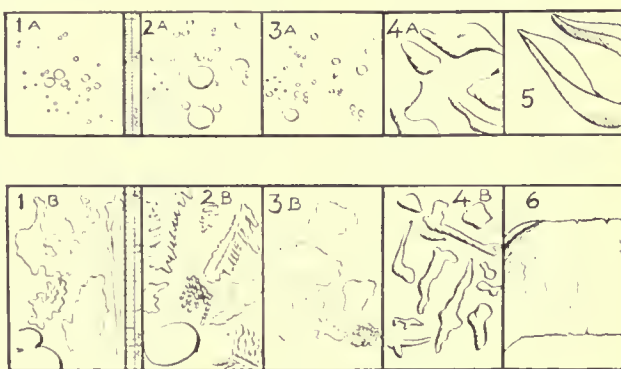

By raising or lowering the working cylinder the velocity can be adjusted, the effective head *h* being the vertical distance of the top of the cylinder below the level of the Mariotte tube inlet, the velocity varying approximately as the square root of *h*. The clip on the siphon should be removed or kept wide open during the test, and care should be taken that the rubber connections are not sharply bent or allowed to obstruct the flow. When the point is found at which an upward velocity of exactly 1 cm. per second is obtained, or some point sufficiently near, it is well to mark the position of the cylinder and clamp or measure the height *h*, so that this position can be reproduced, all the other adjustments remaining the same.

Method: Put 20 gm. of zinc-dust in the cylinder, moisten with a little water, then add 50 or 100 c.c. and stir till all air bubbles are removed, then fill cylinder with water. A wire stirrer is used, reaching to bottom. The bottle being filled to *b*, open clip and start the flow. Use the stopwatch as a check on the velocity, timing the first 1000 c.c. The wire stirrer must be used at first to prevent packing; most of the fine passes off with 500 to 1000 c.c. of water, but it is best to let 2 litres flow through. Then allow the remaining material to settle a few seconds, rinse into an evaporating-dish or casserole, decant off water, wash twice with a little alcohol, dry, and weigh the residue. This may be tested with 100 and 200-mesh sieves, if not sifted before making the test, and further examined with the microscope. By commencing the test with a velocity of say 0.8 cm. per second, and repeating with the same material at 1 and 1.2 cm., several distinct fractions may be obtained from the material passing 200-mesh. The comparatively coarse particles are of several kinds: (1) impurities, usually chips or sand; (2) round particles of zinc, or aggregate made up of round particles, looking like grape-shot; (3) feathery or fern-like aggregates of minute crystals of zinc, often forming very thin platy masses.

A separation of the coarser particles can, of course, be more simply made by repeatedly stirring with water in a beaker and decanting, but it is impossible to obtain com-

parable results unless a constant upward velocity is maintained in some such way as indicated.

The accompanying figures illustrate some of the variations shown in the appearance of certain samples of zinc-dust when examined under the microscope. The upper row, highly magnified, show the appearance of the medium portion of the 'through 200' fractions of three such samples, the very finest part (under $\frac{1}{20,000}$ in.) having been removed by classification. As may be seen, these are almost perfect spherules, and under the highest powers appear to have clean smooth surfaces, and to consist of nearly pure metal. The coarser particles, over 0.003 in. remaining on a 200-mesh sieve, are shown below, and vary greatly in appearance. In several of the more satisfactory samples, illustrated by No. 1 and 3, many of these larger particles have a rough coke-like surface, but some generally exhibit branching crystalline, fern-like aggregates, and other aggregates resembling miniature bunches of grapes. It is possibly only a coincidence that the unsatisfactory sample (No. 2) had an unusually large proportion of the fern-like forms and also showed more relatively large spherules in the 'through 200' portion. The extreme minuteness of the fine is shown by comparison with the equally magnified filing

Description of Figures.—(1) Imported (German) zinc-dust; satisfactory, precipitation good. (2) Imported (German) zinc-dust; unsatisfactory, precipitation not good. (3) Domestic (U. S.) zinc-dust; satisfactory, precipitation good. (4) Granular zinc. (5) Zinc filings, passed 200-mesh sieve. (6) Zinc shaving, extra fine about 1/50 in. wide.

(No. 5) which had passed a 200-mesh sieve, and the granulated zinc, also passing 200-mesh (4A), the method of preparation of which is not known, but which had a very low precipitating efficiency.

Surface Exposed by Zinc-Dust.—As the efficiency of this precipitant is mainly due to its fine division or extensive surface, some calculations of the latter may be of interest. To calculate the surface exposed by zinc-dust, use may be made of the fact that the total surface exposed by one ton (2000 lb.) of any material in uniform grains—either cubes or spheres—is $\frac{2304}{gd}$ sq. ft., *g* being the specific gravity of the material and *d* being either the edge of the cube or the diameter of the sphere, expressed in inches. Hence, the density of zinc being very nearly 7, assuming it to be in the form of spheres of a uniform diameter of *d* inch, then square feet surface exposed by 1 lb. = $\frac{0.165}{d}$.

Thus the portion which will just pass a 200-mesh (*d* = 0.003 in.) sieve will expose only 55 sq. ft. per lb., while the material averaging only 0.0001 in. diameter—which constitutes a considerable proportion of the whole, as may be seen by a microscopic examination of the finer portion—exposes 1650 sq. ft. per lb. It is interesting to compare this with zinc-shaving. Assuming this material to consist of a continuous rectangular strip, of width *a* and thickness *b*, then:

Area exposed by 1 lb. zinc-shaving = $0.055 \left(\frac{1}{a} + \frac{1}{b} \right)$ sq. ft. If, instead of being rectangular, the cross-section of the

shaving is a parallelogram of angle A , the above expression must be multiplied by $\text{cosec } A$; in this case the thickness b is measured at right angles to the width a .

For instance, with shavings $\frac{1}{32}$ in. wide and of various thicknesses, the surface exposed would be:

Thickness	1/800	1/1000	1/1500 in.
Sq. ft. per pound.....	45.8	56.8	84.3

The number of particles (spheres) of zinc-dust in a pound, assuming the specific gravity as 7, is $\frac{7.544}{d^3}$. Hence,

if the diameter is 0.001 in., 1 lb. will contain 7544 million particles, while at an average diameter of 0.0005 in. there will be 8 times as many. Thus some idea of the intimate nature of the mixture can be obtained if an emulsion of zinc-dust is prepared by distributing it with absolute uniformity through the solution to be precipitated. Suppose $\frac{1}{3}$ lb. of zinc-dust is used per fluid ton (55,296 cu. in.) of solution, or 1 in 10,000 parts by weight, the diameter of the particles being taken as 0.001 in. From the above figures it appears that each cubic inch will contain about 27,300 particles, if uniformly distributed, whence the average distance between the particles will be approximately $\frac{1}{30}$ in. If the particles are of half this diameter and equally distributed, there will be 8 times as many to the cubic inch, and half the distance apart.

All samples shown in the upper row highly magnified (see scale); those marked (A) are carried off by a stream of water rising 1 cm. per second, but finest dust has been removed. Those marked B remain on a 200-mesh sieve and are less magnified, as shown by the scale beside 1.

In the October *Journal* of the Chemical, Metallurgical & Mining Society of South Africa, is a communication from M. Thornton Murray on this subject. The sample of zinc-dust examined by him appears to have been somewhat coarser than the average, as it is usual to find in the material of less than 0.003 in. diameter a good deal of dust not over 0.0001 in. diameter, and some considerably finer, so that I should be disposed to consider 0.0005 in. more nearly an average for this fraction.

Mr. Murray's assumed gravity (6.92) would give $\frac{0.1665}{d}$ instead of $\frac{0.165}{d}$ which I have assumed for the sq. ft. per lb., or approximately 1% more surface than my formula would indicate. Thus, instead of 144.8 sq. ft. per lb. as calculated by him for a mean diameter of 0.00115 in., my formula gives 143.5 sq. ft. Actually I have found a range from 6.82 to 7.0 in the specific gravity of samples of zinc-dust tested.

Mr. Murray has, however, seemingly obtained his 'mean diameter' by multiplying the assumed diameter of each of his fractions by its percentage weight, and dividing the sum of these products by 100, which is not mathematically correct for the reason that there are far more particles in 1% of the finer grades than in 1% of the coarse,⁵ considering a given weight of the total material. This makes his calculated mean diameter too high, and the resulting surface correspondingly too low. This may be seen by computing the surface for each fraction separately, as below, from Mr. Murray's data for percentages and diameters of the various fractions, the finest fraction alone giving a larger surface than he has computed for the whole.

If the average diameter of the particles in the finest fraction be assumed at 0.0005 in. instead of 0.00085, the surface becomes approximately 330 sq. ft. for each pound of that grade, or 312 ft. for a pound of the total dust, or about 288 sq. ft. of zinc reckoning 90% of metallic zinc, the surfaces exposed by the coarser fractions being negligible in comparison. As others have pointed out in a pre-

⁵This is obvious from a consideration of an extreme case. Suppose a mixture of equal weights of bullets of two sizes, half the weight being balls of 1.0 in. diam., and half of 0.10 in. The mean diameter is not 0.55 in. (as would be found by calculation based simply on distribution by weight), since for every 1-in. ball there are 1000 balls of a diameter of 0.10 inch.

vious discussion on fine grinding,⁷ the results of the calculation depend almost entirely upon the average diameter assumed for the material passing the finest sieve used, which there is no means of precisely determining.

Fraction between	Mean diam. of fraction (d in inch)	Sq. ft. for 1 lb. of fraction 0.165/d.	Percent of fraction	Sq. ft. for 1 lb. of total zinc.....	Sq. ft. for 0.90 lb. of metallic zinc.....

Nickel in Canada, 1911

The mining and smelting of nickel-copper ores in the Sudbury district of Ontario was carried on actively throughout 1911, and although the production was slightly less than in 1910, it was still very much larger than in any previous year. Active operations were, as usual, carried on by the Mond Nickel Co. at Victoria mines and the Canadian Copper Co. at Copper Cliff, Creighton, and Crean Hill, while the Dominion Nickel Co. continued to develop its property at Norman Station.

The ore is first roasted and then smelted and converted to a matte containing from 77 to 82% of the combined metals, copper and nickel, the matte being shipped to the United States and Great Britain for refining. A portion of the matte is now used for the production of monel metal, which is obtained directly from the matte without the intermediate refining of either nickel or copper. The total production of matte in 1911 was 32,607 tons, valued at the smelters at \$3,945,593, a decrease of 2462 tons, or 6.9% from the production of 1910. The metallic contents were copper, 17,932,263 lb., and nickel, 34,098,744 pounds.

The aggregate results of the operations on the Sudbury district nickel-copper ores during the past four years were as follows, in tons:

	1908.	1909.	1910.	1911.
Ore mined	\$ 409,551	\$ 451,892	\$ 652,392	\$ 612,511
Ore smelted	360,180	462,336	628,947	610,834
Matte produced...	21,197	25,845	35,033	32,607
Copper content of matte	7,503	7,873	9,630	8,966
Nickel content of matte	9,572	13,141	18,625	17,049
Value of matte shipped	\$2,930,989	\$3,913,017	\$5,380,064	\$4,945,592
	Pounds.	Pounds.	Pounds.	Pounds.
Exports to Great Britain	2,554,486	3,843,763	5,335,331	5,023,393
Exports to U. S. ..	16,865,407	21,772,635	30,679,451	27,596,578
	19,419,893	25,616,398	36,014,782	32,619,971

MICHIGAN is the second salt-producing state in importance in the Union, being surpassed only by New York. The output of salt in the state in 1910, according to the U. S. Geological Survey, was 9,452,022 barrels, or 1,323,283 tons, valued at \$2,231,262. The total salt production in 1910 was 30,305,656 barrels, against only 979,306 barrels imported, valued at \$370,922. At the same time salt to the value of \$320,926 was exported. The indications are that the salt production for 1911 will show an increase over the figures for the preceding year.

AMERICA has only one-fourth of the total number of electrolytic copper refineries in the world, but these produce 86% of the world's output of copper.

^cApproximate true mean diameter calculated back from total surface by formula $(0.165/d = \text{sq. ft. per lb.})$

Work of the Utah Copper Company

By D. C. JACKLING

THE MINE

Development.—The total amount of underground work done in the original Utah Copper group during the year 1911 was 8930 ft., making a grand total done since the mine was opened of 190,271 ft., or 36.04 miles. During the year 33,504 ft. of new underground work was driven in the original Boston Consolidated group, making a total in that area since the commencement of development of 188,947 ft., or 35.78 miles. The total of all underground development, consisting of adits, drifts, and raises, done since the beginning of development and up to the end of the year 1911 was 379,218 ft., or 71.82 miles. Of this total, 217,591 ft. or 41.21 miles, have been destroyed by underground mining and surface operations, and the total length of underground workings remaining accessible in both groups at the end of the year was, therefore, 30.61 miles.

During the year 1911, 15 churn-drill holes were driven for development purposes, the aggregate depth of which was 8533 ft. The combined depth of all diamond-drill and churn-drill holes existing previous to 1911 was 10,015 ft., and the combined depth at this time of all drilling, comprising 42 holes, is, therefore, 18,548 ft., the average depth of hole being 442 feet.

The cost of underground development for the year amounted to 15.66c. per ton for all ores mined from underground. Development costs applying to all ores shipped from the mines, both from underground and surface operations, was 4.11c. per ton. The cost of churn-drill development during the year amounted to 1.20c. per ton on the total ore produced from both sources. The cost of both underground and surface development work, therefore, amounted to 5.31c. per ton of ore mined. The whole of this cost was charged to operation and is included in the per ton mining costs for the year.

Ore Area.—At the end of the year 1910 there had been outlined in the Utah and Boston groups, by underground workings and churn-drilling, a known ore area fully and partly developed of 166.15 acres, of which 114.63 acres were in the original Utah Copper area and 51.52 acres were in the original Boston Consolidated group. During the year 1911 the total area of ore fully and partly developed was increased to 214.61 acres, of which amount 119.46 acres are in the original Utah group, 86.94 acres in the original Boston group, and 8.21 acres in the Pay Roll group. The average thickness of developed and partly developed ore at the end of the year 1910 was 345.5 ft., and by the end of the year 1911 this average thickness had been increased to 418 feet.

Ore Reserves.—By the churn-drilling in various parts of the property, and by underground development in the southwesterly portion of the orebody, during the year 1911, a large additional tonnage of ore was developed, both laterally and in depth, so that it became necessary to make a complete recalculation of the developed and partly developed ore in the entire property. The orebody was reblocked, and for the purpose of determining the average thickness of capping and ore, 32 longitudinal sections, as well as a large number of other sections which were necessary in order to determine the amount of capping and ore in the slopes, were made and used.

After deducting all the ore that had been mined from the property previous to January 1, 1912, there yet remained 301,500,000 tons of fully developed and partly developed ore, of which amount 229,830,000 tons were fully developed and 71,670,000 tons partly developed. The above mentioned tonnage of developed and partly developed

ore includes about 26,790,000 tons of partly developed ore in the slopes of the steam-shovel workings. Of the fully developed ore, the average assay of 62,040,000 tons is 2% copper, the average assay of an additional 92,130,000 tons is 1.60% copper, and the average assay of the remaining 75,660,000 tons is 1.30% copper. The average assay of the 71,670,000 tons of partly developed ore is 1.28% copper, making the average assay of the 301,500,000 tons of developed and partly developed ore 1.532% copper. As it will not be possible in mining operations to keep the ore absolutely clean, the average assay of all the ore is considered as 1.50% copper. In this connection, it is of interest to note that during the entire life of both the Utah and Boston mines there was mined and milled, previous to January 1, 1912, a total of 15,885,521 tons of ore, having an average assay of 1.6018% copper. In making the calculations to determine the tonnage of both classes of ore, the same factor was used for the 1911 estimates as for those made in 1910, namely, 13 cu. ft. of rock in place per ton of ore. In obtaining the average assay of the 301,500,000 tons of ore, there were used 38,824 assays, representing 14,035 ft. of diamond-drill holes and churn-drill holes, and 246,900 ft. of drifts, raises, and winzes, or a total of 260,935 linear feet of development.

In addition to the above-mentioned tonnage of ore, there is a good mining assurance of developing a considerable tonnage of profitable ore immediately adjacent to and outside of the boundaries of the 214.61 acres of ore area mentioned on the next page. Some work has already been done in this material, but not sufficient to make possible any definite statements regarding its quantity or quality. In the northeastern part of the property there is an extensive mineralized area that has not yet been prospected, and there are indications that warrant the expectation of finding a large tonnage of ore in that part of the property. There is also a good possibility of developing more ore in depth underneath the area already covered by development. In the churn-drill prospecting it has frequently been necessary to abandon holes, although the bottom samples were of commercial grade, because of difficulty in drilling, and it is safe to say that the results of deeper drilling will show a greater average thickness of ore in the 214.61 acres than the 418 ft. previously stated.

Stripping Operations.—In the report for 1910 it was estimated that the average thickness of capping on the original Utah group was 80 ft., and on the original Boston group 160 ft., making an average thickness over the entire orebody, as then developed in the two groups, of 105 ft. During the year 1911 additional data as to thickness of capping were obtained, with the result that at the end of the year the average thickness on the Utah group was still shown to be 80 ft., the average thickness on the Boston group was 134 ft., and the average thickness on the Pay Roll group was 173 ft., making an average thickness over the entire orebody as developed at the end of 1911 of 106 ft. It is believed that further development on the Boston and Pay Roll groups will result in showing reductions in the average thickness of capping, and it is expected that these will be sufficient to bring the average thickness over the entire orebody down to not exceed 100 feet.

During the year 1911 the total amount of capping removed was 5,450,604 cu. yd., or at the average rate of 454,217 cu. yd. per month. During the first six months of the year 2,352,653 cu. yd. was removed, a rate of 392,109 cu. yd. per month, while during the second six months 3,097,951 cu. yd. was removed, an average of 516,325 cu. yd. per month. Previous to the last report

*From a report to the company for the fiscal year ended December 31, 1911.

the total amount of capping that had been stripped from the combined areas of the Utah and Boston properties since the beginning of their development was 7,162,556 cu. yd. Adding to this amount the total amount of stripping removed during 1911, the total 12,613,160 cu. yd. representing all the capping removed previous to January 1, 1912. Of this amount 9,129,170 cu. yd. has been removed from the Utah group and 3,483,990 cu. yd. from the Boston group. The total area upon which stripping operations were extended over an additional area of 47.26 acres, making a total area of 98.51 acres on the Utah group and 33.75 acres on the Boston group, or for the combined properties a total area over which such operations had been conducted up to January 1, 1912, of 132.26 acres.

The extension of the actual area completely stripped on both groups during the year 1911 amounted to 12.65 acres. The area so stripped, as reported in our last annual, was 20.87 acres, making the total of completely stripped area on both groups, at the end of 1911, 33.52 acres. The total yardage removed from both areas represents the equivalent of completely stripping 86.85 acres. Of this area, 70.73 acres is on original Utah Copper ground, where the capping, as previously stated, averages 80 ft. in thickness; the remainder of 16.12 acres is on Boston Consolidated ground, where a capping 134 ft thick exists. This area over which stripping has been completed, or partly so, contains an average of a little more than 1,400,000 tons per acre, and the overburden removed to date, therefore, represents the equivalent of completely stripping over 121,000,000 tons of ore. Of this quantity 15,885,521 tons, or about 13%, has been mined and shipped to the mills. At the time of the preceding annual report, this figure was nearly 20 per cent.

Mining Operations.—Underground mining operations at the Boston mine were continued throughout the year, and for a portion of the time at irregular intervals, some underground mining was done in the original Utah mine on the east side of Bingham canyon. Of the total ore mined during the year, 74% was obtained by steam-shovels from the original Utah Copper mine, 4% was mined underground in the Utah mine, and 22% was mined underground in the Boston mine. The average cost of steam-shovel mining for the year was 33.73c. per ton, of which 9.12c. was charged to cover the cost of prospecting with churn-drills and of stripping expense, leaving a cost, including all general charges, except development and stripping expense, for producing shovel ore of 24.61c. per ton. The average cost of underground mining for the year was 68.35c., of which amount 15.66c. was charged to cover the cost of underground development. The cost of underground mining at the Boston mine was considerably less than at the Utah mine, on account of the greater rate of tonnage at which the operations at the former point were conducted. The average cost of mining all the ore obtained both from surface operations and underground operations during the year was 44.79c. per ton, of which 12.81c. was charged to cover prospecting with churn-drills, underground development, and stripping expense, leaving a net cost for actual mining, including general and fixed charges, of 31.98c. per ton.

It is still the purpose to discontinue underground mining as soon as possible, but it has not been possible to do so as rapidly or as soon as was predicted in the preceding report. The areas which are now being stripped on Boston Consolidated territory are those over which the capping is thickest, and it will be some months before any material tonnage can be derived from them. It is not expected to be able to furnish the plants with a tonnage entirely from steam-shovel mining, even at their present capacity, until some output can be secured in this way from the Boston area. Furthermore, the capacity of the plants is being increased rapidly, as will be hereafter described, and the result of the two circumstances will probably be that it will be found necessary to continue some underground mining throughout the current year.

Equipment and Improvements.—During the year there were added to the mine equipment 20 standard-gauge 12-yd. steel dump-cars, 2 steel under-frame flat cars, and 2 standard-gauge 50-ton locomotives, making the complete list of this class of equipment at the end of the year: 22 standard-gauge steam-shovels, 35 standard-gauge switching locomotives, 1 standard-gauge Shay locomotive, 11 narrow-gauge switching locomotives, 100 standard-gauge 12-yd. dump-cars, 117 standard-gauge 6-yd. dump-cars, 144 narrow-gauge 4-yd. dump-cars, and four 100,000-lb. capacity flat cars. There are also 11 churn-drills used in drilling for development and blasting purposes.

It was found necessary during the year to change the position of the machine-shop and the compressor plant at the Utah mine in order to provide more capacity in the auxiliary yard for the use of the Bingham & Garfield railway. It was also necessary to provide an additional air-compressor of 2300-cu. ft. capacity, making two of this size on the Utah property. Four small compressors were acquired with the Boston Consolidated property, and these are still in operation, the total capacity of all compressors now available for use being approximately 8000 ft. of free air per minute.

Claims and Lands Owned.—There have been some small changes in acreage from that shown in the preceding annual report, due in part to the acquisition of additional property and in part to an error in the last report in the statement of millsite acreage acquired from the Boston Consolidated company near Utah lake.

	Acre.
Original Utah Copper claims.....	194.938
Original Boston Consolidated claims.....	359.729
Outlying fractional claims.....	8.158
Shawmut Consolidated group of claims.....	100.721
Pay Roll group of claims.....	60.324

Total area of lode mining claims..... 723.870

In addition to the above, the millsites and other lands owned by the company are as follows:

	Acre.
Bingham Canyon lands (old Copperton plant site).	1587.39
Garfield lands at Magna and Arthur plants and adjacent to them	3357.94
Utah and Davis county lands near Utah lake, acquired with Boston Consolidated property....	668.49
Total	5613.82

CONSTRUCTION AND OPERATION AT THE MILLS

Construction.—No extensive improvements or additions were made at the Magna plant during the year. The capacity of the coarse-crushing departments was increased by the installation of a screening plant in the coarse-ore bins to remove a greater percentage of fine material as the ore is dumped from railroad cars and thus relieve the crushers. This arrangement has proved of material advantage, particularly in seasons when the ore comes to the mills wet. The shops and warehouse here were increased in capacity to an extent necessary to accommodate the work of the Bingham & Garfield railway. The work of remodeling the Arthur plant continued throughout the year at such a rate as was necessary to complete sections as rapidly as they were needed to accommodate the increase in tonnage from the mines. The first section of the remodeled plant was started up in February, and another section was started before the end of the first quarter. During the second quarter, two additional sections were started and, about the end of the second quarter, the entire stamp-mill portion of the plant then in operation was permanently closed down, as the four remodeled sections were capable of milling practically as much tonnage as the thirteen original stamp-mill sections of the plant. The fifth remodeled section was put in commission during the third quarter, and the sixth section before the end of the year, at which time the seventh and eighth sections were also nearly completed. The seventh, eighth, and ninth sections have since been completed and the seventh and eighth put in commission. The

ninth section is ready to receive ore at the date of writing this report. The reconstruction of the four remaining sections of the Arthur mill can be completed as rapidly as required, and it is the present intention to finish the last one about the middle of the year.

During the year the capacity of the foundry department at Arthur was increased by erecting an entirely new and larger building. This was done in order to accommodate the business of the Magna plant and the Bingham & Garfield railway; and now all the iron and brass castings required at the mills and the mines and by the railroad are manufactured at this foundry.

Operations at the Mills.—The total ore treated at both plants for the year was 4,680,801 tons, as compared with 4,340,245 tons for the previous year. The Magna plant milled 3,725,404 tons, an increase of approximately 515,000 tons, as compared with the previous year. The Arthur plant, the full capacity of which was not required throughout the year, milled 955,397 tons, an increase of about 18,000 tons as compared to the previous year. The Magna plant has readily handled 1000 tons per section per day during periods when the ore-supply was plentiful and regular, thus proving its ability to treat 12,000 tons per day. The new sections of the Arthur plant have, under like conditions, milled at the rate of 9000 tons for the entire plant, and it is, therefore, demonstrated that the two plants will, when Arthur is completed, have a combined capacity sufficient to economically mill 21,000 tons per day of the same grade and character of ore milled during the past year.

The average copper content of the ore treated at both plants was 1.51%, as compared with 1.54% for the year 1910. The average recovery at both plants was 69.53%, corresponding to 21.03 lb. copper per ton, as compared to an average extraction of 66.55% and a recovery of 20.51 lb. for the previous year. The average extraction at the Magna plant was 69.28% and at the Arthur 70.49%. The average recoveries stated for the Arthur plant include the comparatively inferior results of the portion of the old mill in operation up to the middle of the year, and the average results experienced at that plant, since the operation of the old sections was discontinued, are comparatively better on the same grades and quality of ore. In fact, it is apparent that the new arrangement of the Arthur plant is superior to that of the Magna mill in point both of economy of operation and metallurgical results.

The average cost of milling at both plants was 41.68c. per ton, as compared to 46.63c. for the previous year. The milling cost at Magna was 40.06c. and at Arthur 48.01c. per ton. The higher cost at Arthur was due largely to the operation for a part of the year of the old sections of the plant, but partly to intermittent running at less than full capacity. When this plant is running at full capacity, it is expected that its costs will, as previously suggested, be somewhat lower than those of the Magna plant. The milling costs stated include their proper proportion of all fixed and general charges.

Production and Costs.—The total production of copper contained in concentrate from both plants for the year was 98,436,224 lb., as compared to 89,019,511 lb. for the previous year. The average grade of concentrate produced was 25.62%, as compared to 27.28% for the year 1910. The reduction in average grade of concentrate was due principally to the treatment of ores mined from underground in the Boston Consolidated area which contained a somewhat higher percentage of iron than the ores from the Utah Copper area. The production for the year by quarters is as follows:

	Pounds.
First quarter	21,296,709
Second quarter	24,469,812
Third quarter	25,851,456
Fourth quarter	26,818,247
Total	98,436,224

The average cost per pound of copper produced, based on the net pounds of copper resulting after smelting reduc-

tions and allowances were made and after applying credits for gold and silver recovered, was 7.8655c., as compared to 8.069c. for the year 1910. The net value of the gold and silver recovered amounted to 1.07c. per pound. The costs given include all expense of smelting, transportation of the blister copper to the refinery, refining, and selling expenses, but do not include delivery of refined metal.

The average total cost for the year of mining and milling, exclusive of transportation charges, was 86.47c. per ton, as compared to 87.6c. per ton for the previous year. Included in this cost is the charge, previously referred to in the discussion of mining costs, of 12.81c. per ton, covering the expense of drilling and underground development and including a fixed charge of 7½c. per ton for the retirement of stripping expense.

As will be seen by a comparison of the milling costs for the past two years, these are being reduced continually, and further reductions will result from the treatment of increased tonnage. It is obvious, from a comparison of the costs of steam-shovel and underground mining, that the mining costs will be materially lower when the entire ton-

SALT LAKE CITY AND VICINITY.

nage can be derived from surface operation. The costs of transportation of the ore from the mines to the mills will be decreased for the future by contract provision that became effective early in the year 1912 by 2½c. per ton, as compared to these charges for previous years. Economies in the cost of power, water-supply, and other operating factors are also being made and, taken together, these will result at an early date in a very substantial reduction in the cost per pound of producing copper.

BINGHAM & GARFIELD RAILWAY

Grading for the Bingham & Garfield railway was started on April 22, 1910, and completed in August 1911. During that period there was removed in excavations for the line 746,970 cu. yd. of solid rock, 618,222 cu. yd. of loose rock, and 315,079 cu. yd. of earth, a total of 1,680,271 cu. yd. Four tunnels were driven having an aggregate length of 4798 ft., of which it was found necessary to line 2963 ft. with timber. These tunnels are all in the first three miles of line from the Bingham end. In that distance there are also three steel bridges containing about 3000 tons of steel and having an aggregate length of 2000 ft. The maximum heights of these bridges, beginning with the one across Carr fork at the upper end of the line, are 190, 225, and 188 ft., respectively. The total length of tunnels and bridges, together with their approaches, in the upper three miles of the line constitute about one-half that distance. The

main line between the Utah Copper mine and the mills at Garfield is laid with 90-lb. steel. The extension from the mills at Garfield to connect with the San Pedro, Los Angeles & Salt Lake railway and the yards at all points are laid with 65-lb. steel. The line was completed and put in operation for freight service on September 15, 1911.

At the end of the year 1911 the tracks belonging to the Bingham & Garfield railway already constructed and in use for ore and commercial purposes were as follows:

	Miles.
Main line from Garfield to the mines, including the track to the Garfield smelter.....	22.296
Yard and siding tracks at Garfield and Bingham and along main line, including extension of the switchback system at Bingham necessary to reach Utah Copper and other mines.....	19.910
Other tracks at Bingham which the Utah Copper Co. has the right of use.....	34.200
Total	76.406

A double-track incline tramway 554 ft. long has been constructed for the handling of passengers, express, and light freight between the Bingham station of the railway and a substation near the centre of the town of Bingham.

As has been previously stated, freight service was started on September 15, 1911, and at the same time passenger service, consisting of two trains each way per day, was inaugurated between Bingham and Salt Lake City. Up to the end of the year the total traffic amounted to 754,584 net tons of ore and other freight, and the total number of passengers handled was 15,276. The facilities for handling freight and passengers at the Bingham terminal were not completed until late in the year, and the business of the line suffered accordingly. Since these were completed, business has been increasing rapidly. The operation of the road has proved satisfactory and economical in every respect. The heavy Mallet compound locomotives readily handle a train of 40 ore-cars containing 65 net tons each of ore, a net trainload of 2600 cars, between the mine and the mills at Garfield in 1 hour and 30 minutes, the 'empties' being returned to the mine in the like time without the assistance of additional motive power. It, therefore, requires less than one shift's service of 10 hours for two train crews to handle 10,000 tons per day.

Copper Producers' Association Report

The Copper Producers' Association May statement shows a decrease during the preceding month in accumulation in this country of 2,927,829 lb. The details are as follows:

	Pounds.
Stock of marketable copper of all kinds on hand at all points in the United States April 1, 1912	62,367,557
Production of marketable copper in the United States from all domestic and foreign sources during April	125,694,001
Deliveries for consumption, April.....	69,513,846
Deliveries for export, April.....	53,252,326
Stock of marketable copper of all kinds on hand and at all points in the United States May 1.	65,295,386
The changes in surplus since May 1, 1911, have been as follows, in pounds.	
	Increase.
May 1911	440,024
June	8,561,768
July	19,695,306
August	4,297,357
September	7,453,355
October	5,897,214
November	23,212,454
December	22,330,493
January, 1912	22,173,252
February	3,301,944
March	572,431
April	2,927,829
	Decrease.

Alaskans on Alaska's Needs

The following resolutions were passed at a representative gathering of Alaskans from Cordova, Seward, Katalla, Fairbanks, Valdez, Chitina, and other points, held at Cordova April 3 and reported in the *Cordova Daily Alaskan*:

Whereas it appears to be generally accepted by those who are unfamiliar with Alaska conditions that the people of the territory are unable to agree upon matters of proposed legislation by Congress; and,

Whereas, there are certain great vital questions affecting the material progress and development of this vast territory upon which the whole people, irrespective of party affiliation, are united, and upon which they demand immediate action at the hands of Congress; and,

Whereas, by reason of the fact that, among others, there is in attendance upon this convention the delegates of both the Republican and Democratic territorial conventions of the Territory of Alaska, which conventions have just concluded their proceedings and deliberations;

Now, therefore, in order that there may in the future be no misunderstanding as to the matter upon which the whole people of Alaska are united and upon which they demand relief and constructive legislation at the hands of Congress, the following resolutions be unanimously adopted and promulgated:

1. We demand the immediate opening of the coal and oil fields, and the abolishment of the forest reserve.

2. Rail transportation. A trunk line railroad from the Gulf of Alaska to the Yukon is a vital and pressing necessity to the proper development of the territory. Under the present attitude of Congress and the regulations of the Government, private capital is barred from such a venture. We, therefore, demand that the Government immediately construct, maintain, and operate such a trunk road.

3. We demand from Congress liberal annual appropriations for extension and maintenance of roads and trails, and urge the immediate construction from the coast to Fairbanks of a trunk automobile road to facilitate the mail service and other transportation. Our territory is so vast that any appropriation less than one million dollars annually for a number of years will be inadequate.

4. We urge that the present mining laws, in so far as they apply to Alaska, shall be so amended as to prevent existing abuses of staking mining claims by agent or power of attorney, and that the location of association placer-mining claims shall hereafter be prohibited or that the annual assessment work required for said claims shall be increased so that \$100 worth of work shall be required for each twenty acres of said claims.

5. We favor liberal appropriations by which justice may be done to, and care taken of, those worthy pioneers of Alaska who have blazed the way for civilization, but who are themselves often left to an old age of penury and want.

6. We believe that all appointments to Federal offices in Alaska should be made from *bona fide* residents of Alaska.

7. We recommend as a vital need that Government hatcheries be provided from funds derived from increased and equitable taxation of canneries, and that a more rigid inspection be maintained with a view of conserving this great natural resource.

8. We demand that additional lights and beacons be installed along the coast of Alaska.

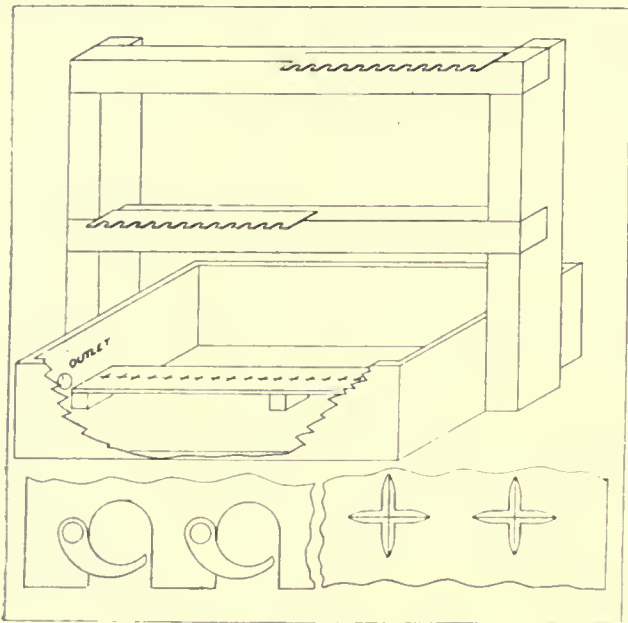

9. We demand a full measure of territorial form of government.

ASPHALT is produced in Switzerland at Travers, Neuchâtel canton, by the Neuchâtel Asphalt Co., of London, England. The annual extraction amounts to about 25,000 metric tons, and there is enough asphalt to keep the company running for a hundred years.

BOLIVIAN tin exports, according to reports given out by the customs authorities, reached 23,499 tons during 1911, a gain of 2000 tons over 1910.

Rack for Drill Steel

Tempering machine drills after sharpening slows down the work unless some sort of a stand is provided so that blacksmith or helper need not hold each drill in position. The one figured below is in use at the Treadwell mines, and its essential features are a rack that holds the drill rigidly vertical and a supporting plate that allows the edge of the bit only to stand in the water. As shown in the illustration, notched iron plates are provided at suit-

ALASKA TREADWELL DRILL RACK.

able heights to receive the shanks of long and short drills. In the detailed drawing, at the lower left-hand corner, is shown the locking device which holds each drill firmly in place. In the lower right-hand corner is a detail showing the slotting of the supporting plate which is fixed in the box at the proper position with reference to the outlet. In the drawing the latter is shown too high, as only the tip of the drill should rest in the water. The box is made of wood except for the supporting plate and rack, which are cut from boiler plate. A flow of water through the box is maintained and at the proper instant each drill is taken from the box and quenched under the outlet flow.

Loss of Copper in Slag

The slag losses of copper, other than mechanical, depend upon the composition of the slag, according to V. Van-yukov in *Metallurgie*. Both matte and slag are electrolytes, the concentration of the different ions varying with the different amounts of the elements present. It is evident that the concentration of cations of a given base in the slag will be affected by the presence of sulphur compounds of this base. The higher the concentration of given base in the slag, the greater the tendency to dissolve sulphur compounds of this base, and along with it some associated Cu_2S . The degree of this tendency decreases with the affinity of the element for sulphur and the degree of dissociation of the silicate and sulphur compound. The affinity for sulphur of various metals is in the following order: Cu, Ni, Co, Fe, Mn, Zn, Ca, Mg, Al. With slags high in the metals near the end of the series the losses in copper are much lower than with slags high in the metals at the beginning of the series.

CONSTRUCTION of the new Nahuel Huapi railway in Argentina, with its extensions across the Andes, is well advanced on the Argentine side between Port San Antonio and Port San Carlos de Bariloche, and the work may be completed within two years.

Utah Copper Quarterly Report

The following tables show the gross production of the Utah Copper Co. for the first quarter of 1912 and the preceding quarter, of total copper contained in concentrate, according to the quarterly report of the president, C. M. MacNeill:

	Pounds.		Pounds.
January 1912....	8,156,612	October 1911....	8,660,729
February "	8,612,739	November "	9,117,961
March "	8,160,199	December "	9,039,557
Total	24,929,550	Total	26,818,247
Av. mo. prod....	8,309,850	Av. mo. prod....	8,939,416

The total amount of ore treated at both milling plants for the quarter was 1,299,315 tons, as compared with 1,365,910 tons for the previous quarter. The Magna plant handled about 69% and the Arthur plant about 31% of the tonnage. The average grade of ore for this quarter was 1.435% copper, as compared with 1.418% copper for the previous quarter. The average cost per pound of net copper produced during the quarter, after making allowances for smelter deductions and without crediting miscellaneous income, was 8.62c., as compared with 7.85c. for the fourth quarter of 1911. The difficulty of conducting operations at both the mines and the mills during the severe winter weather that prevailed throughout the entire quarter and the consequent decrease in production was responsible for this increase in cost. The following tabulation shows the financial results of the operations of the company for the quarter:

Net profits from milling operations for the quarter	\$1,409,985.66
Additional income from rents and miscellaneous sources in Utah.....	12,478.76
Income from Nevada Con. Copper Co. dividends	375,187.50
Total net profit for the quarter.....	\$1,797,651.92
Dividends paid	1,181,287.50
Net surplus for quarter.....	\$ 616,364.42

These earnings are computed on the basis of 14.25c. per pound for copper for the months of January and February, and 15.25c. per pound for copper for the month of March. At the close of the quarter no copper due for delivery from the refinery remained unsold. The Magna plant was in continuous operation throughout the quarter, but its capacity, as well as that of the remodeled sections of the Arthur plant which were in operation, was below normal on account of the constantly cold and stormy weather during the quarter. The frozen condition of the ore prevented rapid unloading of the cars during the cold weather, and during moderate weather the ore was so wet on account of melting snows that it was difficult to put anything like regular tonnage through the coarse-crushing departments. Steps are being taken to protect operations against a recurrence of this condition.

The seventh remodeled section of the Arthur plant, or old Boston Consolidated mill, was completed and placed in operation about the middle of January; the eighth section, the last of February, and the ninth section early in April. The stripping work was hampered by the severe winter weather and a constant scarcity of fuel. During the quarter there were removed from the Utah and Boston groups a total of 1,354,761 cu. yd. of capping, as compared with 1,520,058 cu. yd. removed during the fourth quarter of 1911, being a decrease of 165,297 cu. yd. The Bingham & Garfield railway did a good business during the entire quarter, an average of 7910 tons of ore per day having been hauled from the mines to the mills, and an average of 571 tons per day of other freight having also been handled over the line from Garfield to the mills and mines.

Discussion

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Insertion of any contribution is determined by its probable interest to the readers of this journal.

Russian Platinum Prices

The Editor:

Sir—In the issue of your valuable paper dated April 27, in the article 'Russian Platinum Market,' the current price for 83% platinum is given as 9 rubles 90 kopeks per 'pood'—which, evidently, is meant per 'zolotnik.'

Below are the weights used in the Russian metal market:

1 pood = 40 funt = 36.112 lb. = 16.3805 kg.

1 funt = 96 zolotnik = 0.9028 lb. = 0.409 kg.

1 zolotnik = 96 dolya = 0.1504 oz. = 4.2659 gm.

1 dolya = 0.686 grains = 44.436 mg.

The tenor of placer gravel is usually given in terms of 'dolya' per 100 'pood,' making the relation in weights as 1:36,864,000. In approximate calculation, 1 'dolya' of gold is valued at 5 'kopeks' = 2.5 cents, and 100 'pood' might be taken as the weight of 1 cu. yd. gravel (about 3600 lb.).

ALEXANDER J. HEINDL.

Berkeley, California, May 1.

The Mine-Owners' Liability for Accidents

The Editor:

Sir—Mr. F. J. Martin, of Angels Camp, whose recent article inspired this series of letters, is quite sure that the added cost of mining gold attendant upon requiring the mine-owner to compensate his injured workmen cannot be passed on to the ultimate consumer of gold because, "As everyone knows, *gold has a fixed value.*" Therefore, he insists, the state at large should share this expense with the mine-owner, "since the whole state is benefited by the gold-mining industry." There have been those who have concerned themselves profoundly lest compensation should pauperize the hurt man, and they have characterized the Roseberry measure as one calculated to 'wet nurse' him into a position of dependence upon public bounty. If our experience with 'wet nursing' American industries may be taken as a guide, we should be duly cautious about 'wet nursing' anything into a condition of dependence upon public subsidy, and especially against a nursing bottle with a gold nipple. How those 'infant industries' of ours, like the United States Steel Corporation, the harvester trust, the sugar trust, and the rest, do squall when Congress makes a feint of proceeding to take the nursing bottle away!

Let it be clearly understood that the failure of each industry to take care of its own hurt men, and those dependent upon them, is, and always has been, a downright bonus to such industries paid into their treasuries by poverty and property; first, by the hurt man, who was denied the recompense for his hurt to which he always had a moral if not a legal right; by the dependent children of the hurt man, who were forced into orphanages or out into the world of industry while they should have been at school; by property, in that it has found, even in this young and rich state of California, the pauper problem one of the most exacting to be solved; and again by property, in that it has had to bear the cost of the criminality that indubitably grows out of poverty. Ever and always industry has enjoyed this bonus, and few there are among our industries that feel that they can live if this bonus is taken away.

That gold mining is of advantage to the state is true, but so is farming, and the California farmer is lying awake nights through fear that he may have to pay for the injuries that befall men who help him to grow his crop. And so on down the line! All admit the justice of compensation, for that cannot be denied, but each industry for itself protests that it can by no means bear the cost and that either the hurt man must bear the burdens as heretofore, or else that

plethoric person known as the state at large. All want to 'let George do it.' Let me lay down a fundamental proposition: that industry which cannot survive except it receive a bonus of unrequited claims from mangled men, widowed women, and orphaned children, will best serve the state by winding up its affairs and quitting so unprofitable a business. That business which, after it has been boosted over a limited period of infancy, cannot make its own living, pay its own way, and leave nothing unpaid that it morally owes, has no right to exist, and surely gold mining is no infant industry in California. It is the oldest of all and the author of many.

It is not at all times easy to see when, and how, and where, in any industry, the ultimate consumer pays the compensation benefits that go to hurt men and women, and it is not always that the ultimate consumer will pay such compensation benefits, but, with few exceptions, he eventually must. Mr. Martin is fundamentally wrong when he declares that gold has a fixed value. Its value is as unfixed as the surface level of the sea. Its value ebbs and flows with every increase or diminution of output, with every new demand in commerce or the arts, and the worst of it is that in swashing around in its world-volume bed, gold fixes and unfixes the value of every other commodity known to human use. This is because gold is both a commodity and a world-measure of the value of all commodities, in which latter function it operates by contraries. Whatever invention or device decreases the cost of mining gold increases the output of gold and, to that extent, tends to cheapen gold and raise the gold price of everything else. *Per contra*, whatever increases the cost of mining gold, to that extent diminishes the supply of that metal and tends to raise its value. This is known by the token that the prices of all other commodities begin to tumble when gold goes up. Gold enjoys no exemption from the law of supply and demand that acts so potently with other commodities.

Now it is as certain as anything else of which the operation cannot be seen, as certain as that electricity exerts power, that the consumers of all products except gold foot the bills for the creation of those products, and gold is as much a product of industry as coal, and those laws that operate in fixing the price of coal operate just as certainly in fixing the price of gold, only the other side up. In Illinois, for instance, in order to enable the coal operators to pay a death benefit of \$2250 for each miner killed, instead of \$168, as has obtained for many years under the old order, will require the addition of 1.6c. per ton to the price of all coal mined in that state. I do not know just how much more an ounce of gold would be made worth if a similar increase in death benefits were required to be paid for all gold miners killed. The fraction might be infinitesimal, but it would be there, and the producer of all commodities, rather than the consumers, would pay the bill, because, as above explained, gold as a measure of commodities operates contrariwise. The point of all this is that the imposition upon the gold miner of California of the cost of indemnifying industrial accidents will, in so far as the gold product of California influences the value of the gold product of the world, be transferred from the gold miner to the producer of all other commodities, although when it is done and how it is done neither the miner nor anyone else will be able to detect in any concrete case. It should suffice to know that it is so. 'The buck' will be passed all right, but let us hope not in the form of a bonus to the mining industry assessed upon other property of the state as a state tax. Gold mining is in no need of passing the hat.

The crux of the whole problem of distribution of this added cost is insurance; and mining insurance comes high. It is so the world over, for mining is a hazardous industry, hazardous to health as well as to life and limb, and occupational diseases need insurance coverage as much and as certainly as industrial casualty. What interests me most is to learn if there is such a community of interest and parity of risk among gold mines as will make it a practical thing for mine-owners to come together and either inter-insure each other against the hazards of accident or form mutual insurance companies for mine-owners only, by which they

may carry their accident risks at what it is worth to insure against them. It is to this subject that, in my judgment, the mine-owners of California should give attention rather than to suggestions for unloading the initial burden or any part of it upon the taxpayers of the state.

The law of liability in damages has, through the abrogation of old defenses, increased the liabilities of employers, mine-owners in common with others, three or four times over, and I cannot promise them that compensation, if elected, will cost them less. Ten years' experience will tell; nothing else can. Meantime, the hazard must somehow be carried. Insurance enables employers to bear one another's burdens and to make a first distribution of each loss over the industry in which the loss occurred, and all that any mine-owner has a present right to demand of the state is to have opened for him a way whereby he may, if he will, best in himself secure insurance coverage at what it is reasonably worth to furnish that coverage. Every industry should care for its own killed and wounded. This is a task which the Industrial Accident Board has in hand, and in its performance it wants and needs the counsel, coöperation, and practical knowledge of every mine-owner and mining engineer in California.

San Francisco, March 25.

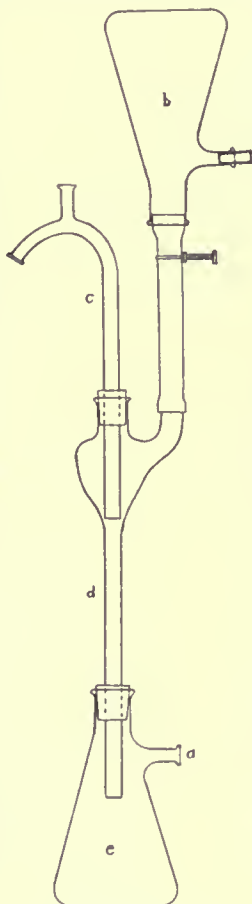

A. J. PILLSBURY.

Laboratory Classifiers

The Editor:

Sir—Elsewhere in this issue W. J. Sharwood describes a simple and cheap type of laboratory classifier, which he employed in the classification of zinc dust. The apparatus there described has the great advantage of being constructed from material available in every laboratory, and served admirably the purpose for which Mr. Sharwood intended it, but if others were to employ it for general work faulty results would be obtained that might vitiate the conclusions reached. For classification of ores it is evident that the velocity of flow to be considered is that at the lip where the material is overflowing, rather than in the body of the tube, and it is likewise obvious that the amount of ore that can thus be classified is too small for convenience in experimental work, since if the ore present in the tube exceeds 1/10 of the volume of the ascending current of water it will give rise to interstitial currents which interfere with the separation.

Since the present trend of ore-dressing practice is toward closer classification, and closer control of mill operations in the light of laboratory experiment, it may be worth while to call attention to the convenient laboratory classifier, shown by the accompanying illustration, which was devised by H. S. Munroe, professor of mining in Columbia University, and first described in the *School of Mines Quarterly*, April 1901, page 303. It consists essentially of two Erlenmeyer flasks of convenient size, a specially constructed feed tube, *d*, and a classification tube, *e*. These are connected as shown. In use, *a* is connected with a source of water supply of constant head, and by measuring the outflow from *c* for a given period and dividing by the area of *d*, previously determined, the rate of flow is computed. The ore, mixed with water, is placed in *b* and the pinch-cock opened sufficiently to allow the desired amount of

MUNROE LABORATORY
CLASSIFIER.

feed, which should not exceed 1/10 the volume of the rising current in *d*. As the ore passes down the feed tube, water passes up into *b* to take its place, thus tending to prevent choking. A small quantity of air at the top of *b* aids in this, as by gently squeezing the rubber tube a pumping action is produced which will free the tube even when choked with quite coarse sand. By re-treating the sized product with successive currents of increasing velocity any number of classifications desired can be made. Both in ordinary ore-dressing and in cyanidation the screening tests which are commonly employed are not so significant as a determination of classification ratios would be. Furthermore, with screens it is impracticable to obtain a closer separation than, for example, through 150 mesh, on 200 mesh, through 200 mesh, while with a classifier any desired degree of accuracy can be obtained.

San Francisco, May 6.

THOMAS T. READ.

Government Bureaus and Potash

The Editor:

Sir—I beg leave to approve of the editorial in your issue of March 30 entitled 'Government Bureaus and Potash.' Many of us who have lived in the West have known for twenty to thirty years that the beds of the dry lakes of the Great Basin region are rich in the various salts of soda, potash, lime, and magnesia. The deposits of many of them were thoroughly analyzed years ago by competent chemists without the aid of Government appropriations. Perhaps all the possible natural salts of soda are present, though the chloride, carbonate, and sulphate of sodium are the most prevalent and the greatest in amount. In certain localities biborate of soda, or borax, is rather common in lesser amounts. Next in order of magnitude in these ancient lake beds are usually salts of lime and magnesia as secondary deposits or recrystallizations; those of sulphates of lime and magnesia being perhaps the most common. In most of the lake-beds potash can be found as nitrate, chlorate, sulphate, or other forms, but in much less percentage than the soda salts. In any given lake-bed a given salt does not usually occur with any special uniformity, either as to areal or vertical distribution. Take Death Valley, for example. The only salt that has been commercially gathered from that locality is borax in the shape of the efflorescence called 'cotton-ball'; but in the deepest part of this 'sink' and over the larger part of its area, chloride, carbonate, and sulphate of sodium occur in much larger quantities. How futile, then, on the basis of analyses from a few shallow wells, to take a pencil and figure the tonnage of any one given salt in the whole lake basin, as has been done by the Government experts in the case of Searles lake. Furthermore, I, for one, do not know as yet that the salts found in the deposits and brines of ancient lake-beds can be isolated or segregated from each other on a commercial scale at a cost commensurate with the lack of transportation facilities which almost always exists. As you well say, "The function of Government bureaus is to disseminate accurate information, not to diffuse sensational statements."

One of the possible minor injuries resulting from ill-considered preliminary reports by members of the Government bureaus, is occurring now in this part of Nevada. Many of my neighbors are investing in potash locations in Railroad valley; and they are doing it largely because an alleged Government expert has spent a day or two there and has reported favorably in general terms. It is hoped that the yield of potash salts will be high in Railroad valley. The locality is certainly more promising than where the Government test-well was sunk near Fallon; but as yet there are not sufficient facts known to determine commercial possibilities.

The self-advertising methods of Government bureaus, and disinclination to give credit to earlier and capable workers in a private capacity in the same field, is shown by a little history of the Western phosphate deposits. Many years ago I was invited by a cowboy to see an outcrop of coal which he thought he had discovered in a certain

locality in southwest Wyoming. Before the outcrop was seen it was decided it could hardly be coal, as the nearby formations were much older and of a lower geological horizon than the Laramie formation of the Cretaceous in which most of the coals of the West occur. Samples of the dark outcrop were taken, and were shortly afterward determined to contain calcium phosphate. It did not occur to me, at the time, that there were commercial possibilities in the material, and I can hardly see it now unless the transportation facilities be greatly improved. Now it seems that at a later period, but unknown to me until a recent date, one Charles Colcock Jones, a good economic geologist, had examined the same formation in another locality. His observations and investigations were accurate and scientific as far as they went, and he reported his results to the Geological Survey. Not long after it was heralded in trumpet tones that the experts of the Survey had 'discovered' phosphate beds in Wyoming, Idaho, and Utah of vast extent, containing millions of tons of valuable phosphate. So far as I know, none but the most perfunctory allusion and credit to the excellent work of Mr. Jones has been made in the Government publications.

However, the object of this communication is to give information to those who may be interested, rather than to be critical. The purposes and objects of the bureaus investigating sources of fertilizers are excellent, and good will come of them to the country. Potash attracts much attention now on account of the well-known German monopoly. Phosphates are important. Are not nitrogenous fertilizers about equally as important? The largest known area of nitre beds in the United States, the upper portion of which beds is identical in character with the *caliche* of Chile, but of somewhat lower grade, are worth a word or two. Nitrate, chlorides, and phosphate of potash are found in the same beds, but, so far as known to me, only in small quantities. It is possible that in certain localities a high percentage of potash salts could be found by scientific exploration. The surface material was fully analyzed as long ago as 1883. For 30 years some of the lands embracing the beds have been located and relocated many times. Some of them are now held by people unknown to me. The locality is on both sides of the line between San Bernardino and Inyo counties, California, and within the drainage area of the Amargosa river. Some three miles south of Tecopa station of the T. & T. railway the river, which here flows toward the southeast, begins to curve southwesterly. Gradually turning, it then flows westerly for a considerable distance, and bending northwesterly and then northerly, finally empties into the south end of the present sink of Death Valley. The beds in question occupy a broad belt along this portion of the valley and extend out from the channel of the river for several miles on either side. Some four miles below, or south of, Tecopa station, Willow creek joins the drainage from the east, and about two miles up Willow creek from its mouth is the present ranch of 'Dave' Morrison, formerly known as the 'China' or Evans ranch. The easterly line of the belt commences some miles east of the Morrison ranch and extends thence westerly to a line perhaps 10 miles west from the northerly turn of the Amargosa—a distance of perhaps 45 miles. These beds are composed in the main of Eocene and perhaps later Tertiary clays and sediments, often several hundred feet in thickness, as shore-line and sea-bottom terraces and layers when the great sink of Death Valley was filled to its brim with a saline lake discharging its surplus waters southerly into the Mohave sink. Finally desiccation of the lake commenced, and continued at intermittent intervals, and the terrace form of the deposits increased. Toward the end of this period the Amargosa commenced to cut down into the bedded deposits, forming the canyon which, heading a few miles south of Tecopa, now extends at least 15 miles. While this action in the river bed was taking place, erosion was rapid and extensive elsewhere, and has continued to the present time, so that these deposits, in the main, now take the surface form of numer-

ous low, round-topped hills, separated by ravines and gullehes. The tops and sides of the hills are everywhere covered with a soft, pulverulent material, almost ash-like in weight and consistence, into which one sinks to the ankles or deeper in walking. This is similar to the *caliche* of Chile and consists of light silicious and aluminous dust permeated with crystals of nitre. From one to several feet beneath the surface are the firmer and more clearly stratified clays.

The nitre in crystals in the *caliche* as well as in the more amorphous form in the underlying clays, is in both places easily soluble, so that the scanty rains of this region have produced depressions and sink-holes in the tops and sides of the hills, connected with irregular caves, galleries, and tunnels deep beneath the surface. Analyses have given as high as 50% or more sodium nitrate in the *caliche* and equally as high in some of the underlying clays, though high results are not so common in the latter. The average of the nitre content is perhaps 30% less than the best Chilean deposits, though I am not well informed on recent results in that district. It has been noticed that in this the different salts segregate by themselves to a greater extent than elsewhere in the lake-beds of the desert, perhaps due to the unusual area and depth of this particular lake basin. Where nitrate of soda occurs in the *caliche* it is often quite free from other salts of soda, or even of all salts. Toward the middle of this belt of deposits are strata of rock-salt 12 ft. thick and 95% of chloride of sodium. It is possible by thorough exploration to find, in certain localities and certain horizons in the clays, nitrate of sodium of high grade. Similarly, good grades of nitrate, chloride, or sulphate of potash might be found. As the salts of this region are generally well separated from each other; as many of them are easily soluble, but differing in solubility at different water temperatures; as water is rather abundant in streams, springs, and wells; and as a railway now crosses the beds, may it not be a locality where profitable production can be had? It may be well to mention in this connection that I am not financially interested in nitre or other saline deposits in the United States, and have nothing to sell except my services and experience.

Manhattan, Nevada, April 10.

J. D. KENNEDY.

Miners' Health

It is announced that an arrangement has been made with the Public Health and Marine-Hospital Service by which one or more surgeons connected with that service will carry on jointly for that service and for the Bureau of Mines investigations looking to the improvement of mine conditions. These inquiries and investigations have already shown the prevalence of tuberculosis and hookworm as miners' diseases in a number of different localities in the United States. It is important that this work should be extended more rapidly, because of the fact that the health conditions, as well as the risk of accidents, may be influenced by conditions susceptible of easy improvement. Furthermore, the large and continuous influx of foreigners into the mining regions of the United States will bring, to an increasing extent, the hookworm and other diseases that abound in mines in parts of certain European countries. Various questions that concern the health of workers in mines, quarries, and metallurgical plants cannot be answered finally without investigations and inquiries that are national in scope. Among such questions are the most efficient methods of preventing the diseases peculiar to certain industries, the most effective sanitary precautions to be observed in and about coal mines and metal mines, and the relative healthfulness of occupation pertaining to mining and metallurgical industries. The investigations and inquiries that are essential to the gathering of reliable information on these questions can be undertaken by the Bureau of Mines, in connection with its collection of accident statistics, in a prompt and efficient manner and at minimum expense.—*Report, Director U. S. Bureau of Mines.*

BOSTON

COPPER MERGER AGAIN.—LAKE MINES.—PRESIDENTIAL POLITICS AND THE BROKERS.—TENNESSEE COPPER.—SULPHURIC ACID AND BRIQUETTES.

The recent visit of a large party of mining and banking men to the Butte district and to Bingham has revived the talk of a copper merger. No sooner was the report circulated to that effect than it was denied. John D. Ryan, who has shown ability as a diplomat and pacificator of conflicting interests, was in charge of the party. He delivered an optimistic speech in Butte as to the copper situation and announced that the bankers who accompanied him had decided to invest \$12,000,000 in Montana during the next twelve months. The party was composed of men representing the Amalgamated, Guggenheim, and Calumet & Hecla interests. Its very composition gave rise and color to the rumor that the much-talked-of merger was again under serious consideration. R. L. Agassiz, vice-president of the Calumet & Hecla, and D. C. Jackling, general manager of Utah Copper, were members of the party. In the denial made it was pointed out that Mr. Ryan is an old Michigan man and has been accustomed to make Western trips frequently in company with Mr. Agassiz. It was further pointed out that Mr. Jackling's presence had no special significance since he had been to Butte recently to examine the Butte & Superior company's property preliminary to new financing by Hayden, Stone & Co., of this city. While there the Anaconda management invited him to examine the Anaconda and affiliated properties. It is believed here, however, that federal or state laws and public sentiment permitting, the copper merger may yet be effected. It is not dead, only sleeping. John D. Ryan has much ability as an executive. The formation of a copper merger under his direction would be quite another thing from the ambitious, pyrotechnic attempt made by Rogers, Rockefeller, Burrage, and Lawson, when Amalgamated was launched as a stock-jobbing project.

The question arises, Why cannot a copper merger be formed abroad? It would doubtless be a last resort, since over half the world's copper is produced in the United States, and the merger should be formed here. London is a great copper market. It fixes copper quotations with practically the same absoluteness as Liverpool does the quotations on cotton. If it be true that the day of \$1,000,000,000 corporations has passed in this country, the copper merger might as well be abandoned. If not, it will undoubtedly come to a head before long, as the coming event continues to cast its shadow before.

The tenth annual report of Copper Range Consolidated has been made. It gives support to the idea that this company has reached the meridian of its career. For several years Copper Range has been looked upon in the Lake country as the ideal copper-mining investment. It now shows earnings of \$2.04 per share for 1911 as compared with \$3.38 per share in 1910. It shows a lower yield per ton and higher costs. Last year the company reduced its dividend, and there is no immediate prospect of a resumption of the old rate. Copper Range has in the past year acquired the Atlantic M. Co. property, where no operation is being done at present, though the Atlantic railroad and mill is handling the output of the Superior Copper Co. The Atlantic acquisition gave Copper Range about 4800 acres of timber land and 2110 acres of miscellaneous lands. The latter include two miles of frontage on Lake Superior suitable for millsites and a deep-water frontage on Portage lake. The deal included the Atlantic & Lake Superior railroad, with 15 miles of standard track, a stamp-mill, a half interest in the Salmon Trout river dam, which furnishes the water-supply for the Baltic and Atlantic mills, 250 houses, \$40,000 in stock in the Michigan Smelting Co., and cash and supplies amounting to about \$135,000. The mineralized part of the Atlantic property consists of about

1400 acres. The Copper Range management has the confidence of Boston and New England interests practically to the same extent that Calumet & Hecla does. The company owns a railroad which traverses the South Range country, being practically in position to serve all the developing mines of that section. The old Copper Range has perhaps seen its best days, but with additional territory and a continuance of its wise management it may renew its former strength.

With the coming of May, Boston is advised of the opening of navigation in Lake Superior. This year this means that production will be rushed there more than ever. Record shipments of copper are reported from the district. The rail rate on copper shipments from Houghton to Boston is 30½¢. per 100 lb., while the rate to New York is 28½¢. The rate to Waterbury, Connecticut, where much copper is shipped to the wire and specialty manufacturers, is the same as the Boston rate. The water rate materially scales the shipping costs, being 10¢. per 100 lb. from Houghton to Buffalo, with about 5¢. added as the rail rate from Buffalo to New York. This makes about 15¢. per 100 lb. by water and rail to New York, as against the through rail-rate of 28½ cents.

A few weeks ago stock market sentiment was almost a unit in favor of the President against Theodore Roosevelt for the presidential nomination. Mr. Roosevelt has gained upon his opponent to such an extent as to break even in the recent primary. It is likely that similar gains have been made among the brokerage organizations. The heads of the firms have usually stood with Mr. Taft, but a great many of the clerks, younger men, came out for Mr. Roosevelt. There was an exception in the case of a prominent banker here who said that, while a personal friend and frequently a host of Mr. Taft, he favored Mr. Roosevelt because he thought him better fitted for the presidency. He stated that Mr. Roosevelt's prompt action in allowing the United States Steel Corporation to take over the Tennessee Coal & Iron Co. averted one of the worst panics this country has ever seen. He believed that under similar circumstances Mr. Taft would have failed to take the initiative as Mr. Roosevelt did. The belief among the soberer elements of financiers is that the presidential campaign this year will exert less influence in checking the improving market which is under way than is usually the case with presidential years.

Boston is always interested in the doings of the Tennessee Copper Co., of Ducktown, Tennessee. The Tennessee company has made a good showing for the first quarter of 1912 and is producing now nearly 1,250,000 lb. of copper per month and 600 tons of sulphuric acid per day. As the summer comes on, the acid production decreases somewhat, due to the delay necessary in cooling the solution. Some improvements have been made in this process which, it is believed, will enable the company to maintain its average rate throughout the hot season. Tennessee is an especially interesting company in that it converts sulphur fumes into sulphuric acid for the fertilizer trade. Being the largest copper mine in the East, Tennessee is sufficiently near the big markets to manufacture sulphuric acid. Its output is taken up several years ahead, assuring it stability of profits for the sulphuric acid department. Recently I was shown sulphite waste pulp which is now used in the process of briquetting coal. It is claimed that this mixture, chiefly of sulphite waste, makes a binding material in every way superior to the tar and pitch heretofore used. It is said that the pulp waste briquette gives forth no odor, while the old briquette is very objectionable for that reason. If sulphite waste can be used as a cohesive material in briquetting the coal-dust which has accumulated in such quantities in the mines of Pennsylvania and elsewhere, the demand for it should be materially increased. Stranger things have happened than that smelter-fume litigation may be disposed of forever and the objectionable sulphur be gathered and bottled up for the trade. As a fertilizer and as a briquetting binder for coal, two large channels are opened for profitable use.

JOHANNESBURG, TRANSVAAL

EAST RAND PROPRIETARY AGAIN.—SIMMER DEEP AFFAIRS.—
NEED FOR LOW-COST DEVELOPMENT.

The East Rand Proprietary Mines continues to attract attention, and naturally the policy inaugurated by the new administration of eliminating as far as possible all ore of an unprofitable grade, even should working costs advance, will be watched with interest. From the accounts already published it appears that the yield under the new policy has been increased from 25s. per ton as the average for 1911 to 33s. per ton for the month of February, while working costs have advanced during the same period from 16s. 4d. to 22s. 8d. per ton, without, however, bringing the total monthly profits up to the level of 1911. It is understood, however, that the profit for March probably will be brought to the 1911 average. If so, it will be interesting to see how these results have been achieved. The superintending engineer, in his report on the 1911 operations, says that under the new policy the yield of the ore milled should approximate the content of the profitable ore reserve. Now, according to the same report, the profitable ore reserve on December 31 was estimated at 6,716,605 tons of an estimated assay value of 6.9 dwt. over a width of 55 in., but according to the report for February the ore going to the mill must have assayed at least on an average 8 dwt. per ton, which cannot be considered close to the assay value of the profitable ore reserves. If the same policy has been extended during March so as to increase the profits by an additional £20,000, there must be a still further divergence between the average screen assays and the ore reserves, and it becomes clear that this is hardly a policy that ought to be allowed. Taking the whole of the Rand, there are only about half a dozen mines capable of maintaining a screen average of 8 dwt. without injury being done to the profit earning abilities of the mine, and the East Rand Proprietary is certainly not one of these favored properties. In two of the mines belonging to this company it is quite possible to obtain such a yield by careful selective mining, but the amount of such ore is limited and fixing the pay limit at the February cost of 22s. 8d. per ton would leave about a third to the developed ore as profitable and available for future working on such restricted lines. If the new policy as disclosed by February results was adopted at the deep-level mines of the Rand it would mean that large areas now being worked at a profit would be quite unprofitable, and it would not require many years of similar policy at the East Rand Proprietary Mines to bring about the same unsatisfactory results. It may, of course, be that this new policy will be only in use for a limited time, and that as soon as possible the sounder policy of obtaining the desired results from treating ore more in keeping with the average assay value of the profitable ore reserves will again be adopted.

Among the more important company meetings held during the week has been that of the Simmer Deep, where conditions illustrate in a striking way the need that exists on the Rand in the immediate future for the exercise of greater economy in the working costs. The Simmer Deep is a property of about 1500 acres, where over half a million sterling has been spent on shaft sinking, and a similar amount stands in the books of the company for unredeemed development. In addition, over a million sterling has been spent on the equipment, but up to the present not a single dividend has been paid to the ordinary shareholders, and at the time of writing it cannot be said that such a dividend is in sight. The chairman, in reviewing the past twelve months of the company's operations, laid stress on the fact that the ore sent to the mill during the year had not exceeded in grade the average of the ore reserves as disclosed by the development. At the same time, he pointed out that it was quite possible to increase the profit for a time by encroaching on the ore of higher grade than the average of the reserves, but it could only be a matter of time before disaster could be expected to follow such a practice.

The position of affairs at the Simmer Deep may be best summed up by stating that at the end of December the ore reserves consisted of 1,312,000 tons of an average grade of 4.9 dwt. per ton. This may seem a low grade, but there are huge areas of similar low-grade ore on the Rand which must be worked and which cannot be expected to give a recovery of more than from 17 to 18s. per ton. It is clear, therefore, that working costs must be kept very low if losses are to be avoided, and if profits are to be made working costs will have to be materially reduced. At the Simmer Deep the only hope of increasing the profits will be by keeping the mill fully employed, and on the Rand, with the mine labor so erratic, this can be attained only by the use of an increased number of small stoping drills, the value of which has been established on the Rand largely by the efforts of the Consolidated Gold Fields. While the new policy at the East Rand Proprietary is to improve the grade by selective mining, the other low-grade properties on the Rand find it necessary to go in for large outputs and low working costs, and there can be little doubt about which is the best policy to pursue in the long run.

KALGOORLIE, WESTERN AUSTRALIA

FEBRUARY DEVELOPMENT.—SHORT MONTH AND CYCLONE
CAUSE SMALL YIELD.—PRODUCTION REPORT.

February was a quiet month. The Sons of Gwalia has announced that its reserves are only 14,000 tons in excess of 1910, and of lower assay-value, and that the profits and dividends will be reduced accordingly. The Horse-Shoe, in the cross-cut from the main shaft of the Great Boulder, at 2650-ft. depth, has cut No. 4 lode 240 ft. from the Ivanhoe boundary, and 15 ft. from the Boulder boundary. The lode is well defined, contains free gold, and for over 7 ft. assays \$25. The Boulder reserves are announced as 698,000 tons, valued at \$14.86 per ton, against 760,000 tons value at \$15.32 for the previous year. Change in the bottom levels is the cause of this decrease, together with the losing of the lode to the Horse-Shoe. The South Kalgurli has reserves of 173,200 tons assaying \$6.16 per ton, against 171,877 tons averaging \$6.30 last year. Regular dividends are paid on this amount. The Oroyo Links' Eclipse lease is showing well at the 7th level, where from 180 to 193 in the south drift the average is \$10.56, over 68 in. The north drift shows \$11.25 ore over 68-in. width. The lessees were working on the Oroya North block, crushed 4742 tons of oxidized ore for a return of \$173,000. After deducting \$37,000 for royalty, and charges for mining, carting, and treatment, there remained \$110,000 to be divided among 5 men for 6 months. An old prospector named Dunn, who located the famous Wealth of Nations mine, near Coolgardie, some 18 years ago, died during the month. He took out some \$100,000 in specimens. The property later was sold for \$750,000 to English capitalists, who produced very little. That was a time when any pot-hole showing a few specimens was bought without proper investigation. Coolgardie is still quiet. A move is being made out at Tindals to work an adjoining mine, but success is doubtful. At Southern Cross, the Bullfinch is proceeding with development and the erection of its plant. Prospecting is still going on in the district, and the Mountain Queen has just published its first return. The mill consists of two Holman pneumatic stamps driven by a gas engine. There is no treatment-plant working yet. During the month 3347 tons was crushed for bullion worth \$13,800. No data are at hand on the actual performance of these new stamps.

In the annual reports of the Inspectors of Mines for the various districts much information is given about the mines; but reviewing those from Coolgardie, North Coolgardie, and Mt. Margaret fields, the general results are somewhat disappointing. It is interesting to note the number of prospects which have suction gas plants and Huntington mills at work on the oxidized ores. The new plant for the Associated Northern at Ora Banda is being rushed, and record work is likely to be done here before long. The country is soft, likewise the ore, and a party on the Gimlet South sunk on the lode, dipping 23°, and a shaft 375 ft.

deep in 30 days, of three shifts each. The shaft is 8 by 13 ft., of arched section, with no timber. This was good work. The death of G. Edwards, of furnace fame, has to be noted. His duplex furnace seems to be almost perfection mechanically, for good roasting. There are many in use in Western Australia, and they are being used in other districts, the latest, perhaps, being at the Goldfield Consolidated. The iron and brass molders engaged in the mine and town foundries have walked out, demanding an increase of pay from \$3.60 to \$4 per day, besides other

changes. They have no chance of getting their demands, and the Chamber of Mines is firm. After many months of heat, we have had one-half inch of rain.

The February gold yield from all mines is valued at \$2,175,000, while the yields from the most important were as follows:

Name.	Tonnage.	Value.	Profit.
Associated	9,900	\$ 63,900	\$ 400
Associated Northern	1,541	23,000
Burbanks Main Lode.....	1,432	17,000
Golden Horse-Shoe	22,778	144,000	†3,000
Golden Ridge	2,720	25,700	8,500
Great Boulder Perseverance..	*9,687	56,500	†8,500
Great Boulder Proprietary..*	16,250	217,500	114,500
Great Fingall	5,994	64,000	6,100
Hainault	4,148	24,500	†5,000
Ivanhoe	18,373	201,000	90,000
Kalgurli	*7,385	68,500	22,500
Lake View & Star.....*	15,411	92,500	15,000
Oroyo Black Range.....	4,340	43,500	15,000
Oroyo Links	10,500	61,500	11,300
Sons of Gwalia	12,420	107,500	30,500
Sons of Gwalia South.....	2,230	14,000	3,000
South Kalgurli	*7,186	47,400	8,500

*Reduced tonnage, on account of cyclone cutting off power from power-house for a week.
†Loss due to various causes.
All returns low on account of short month.

TORONTO, CANADA

DOME MILL DIFFICULTIES.—DEVELOPMENT NOTES.—COBALT.

The Dome mill at Porenpine is operating under difficulties, owing to the trouble with the electric pumps and consequent shortage of water, the lift from Simpson lake, the source of supply, being a heavy one. During April not over 20 stamps were running at once, so that the output of gold was not up to expectations. During the last week of the month gold bars, weighing 130 lb., representing the clean-up from the plates alone for the time the mill has been running, were shipped to New York, the mint at Ottawa not being ready to receive gold. The Hollinger mill is expected to be in operation about the end of the month. It has been delayed considerably by the non-delivery of machinery, owing to litigation in the American courts over alleged infringement of patents. Underground development is increasing satisfactorily. No. 4 vein, when first sampled at the 200-ft. level, assayed only \$8 per ton and is now yielding \$32. No. 2 vein at the same level, which in the report was estimated on a basis of \$4 per ton, runs \$24 in the southern and \$10 in the northern adit. The winze being sunk on the main vein from the 100-ft. level is in rich ore about 70 ft. down. At the Dome Extension cross-cutting continues on the extensive orebody found on the first level from No. 4 shaft. Drills have penetrated 125 ft. of quartz, the width of which is yet undetermined. A good find has been made on the North Dome. In cross-cutting on the 50-ft. level from B shaft, a lens of quartz showing much visible gold has been cut. Another vein of promising character has been intersected from the same shaft. The total gold production from the McIntyre 10-stamp mill, from March 2 to 15 and March 27 to April 18, based on a trifle over 75% extraction, is \$20,000. The free-milling plan is stated to be working well and an extraction of 76½% is being secured from plates and tables. The 5-stamp mill now being installed at the Little Pet is expected to be completed in about two weeks. It will have a capacity of 20 tons per day. The ore is principally free-milling, with coarse gold occurring in the quartz stringers, which are plentiful in the mineralized area and are rich in spots. The Crown Chartered has made the last payment on the Davidson property, on which development is being pushed with a six-drill compressor. A station has been cut at the 400-ft. level. At the Three Nations development on the 100-ft. level has intersected numerous narrow quartz stringers carrying coarse gold. The fate of the Scottish Ontario shortly will be decided by an inspection by a representative of the British syndicate controlling the property, who, after examination, will determine whether any further development will be undertaken. Results from a test of 4700 lb. of ore sent by the Dome Lake to the Kingston School of Mines being satisfactory, the management has decided to erect a 6-drill compressor. The Jowsey claims, having an area of 260 acres, have been taken over by the Gold Peak M. Co. The Pearl Lake has made an assignment, with liabilities of about \$75,000. It is hoped that some arrangement can be made to put it on its feet again, in view of the satisfactory results shown by diamond-drilling at depth. The Plenaureum has cut two veins which show good width and promise well. The Moneta has found rich ore on the 200-ft. level. Ernest Yorke succeeds Mowry Bates as manager of the Hughes.

The bullion shipments from Cobalt since the beginning of the year to the end of April amount to 2,801,358 oz., valued at \$1,625,342. Nearly one-half came from the Nipissing, which shipped 1,243,313 oz. The Kerr Lake and Crown Reserve, which formerly had their ore treated at the Nova Scotia mill, now closed, will in future ship their output to the Northern Customs mill. The financial statement of the Nipissing as of April 1, shows \$1,091,826 cash in bank, \$254,936 ore in transit and at smelters, and \$203,650 ore sacked for shipment, making a total of \$1,550,412. La Rose, as of the same date, reported \$1,619,476 cash in bank and ore in transit and at smelters, and \$89,841 ore sacked for shipment, making a total of \$1,709,318.

SALT LAKE CITY, UTAH

DETAILS OF THE 'COPPER 'LOVE-FEAST.'

A 'love-feast,' at large expense, at which gathered representatives of the Amalgamated and Utah Copper interests, together with a number of other leading financiers, has been causing a large amount of comment as to its significance—if it has any at all. D. C. Jackling, general manager of the Utah Copper and Ray Consolidated, was the host at a banquet last week in Salt Lake City, at which were present John D. Ryan, president of the Amalgamated Copper Co., together with other Amalgamated officials; W. E. Corey, former president of the United States Steel Corporation; C. H. Sabin, vice-president of the Guaranty Trust Co. of New York; J. W. Harriman, president of the Harriman National Bank of New York; D. E. Pomroy, president of the Bankers' Trust Co.; A. Monell, president of the International Nickel Corporation; S. L. Fuller, of Kissel, Kinnecut & Co., New York; P. L. Foster, of the London Exploration Co.; R. L. Agassiz, of Boston, vice-president, and James McNaughton, general manager, of the Calumet & Hecla, together with other men prominently identified with the copper mines of Michigan, Montana, Utah, and Arizona. The party arrived at Salt Lake City from Butte, visited the plant of the International S. & R. Co., at Tooele, one afternoon, and put in the next day inspecting the mines of the Utah Copper Co. at Bingham, the Bingham & Garfield railroad, and the concentrators and smelter at Garfield. At the elaborate banquet on the first evening of their stay, the members of the party said various nice things about each other, Mr. Ryan praising Mr. Jackling and Mr. Jackling commending Mr. Ryan. While the members of the party officially deny that the trip signifies that the long-promised copper merger is actually about to take place, it is the general belief that the trip of inspection of the great copper mines of the country presages still closer relationship between the leading producers, whether the anti-trust laws will be braved by interlocking ownership or not.

BUTTE, MONTANA

J. D. RYAN ON THE PROPOSED GREAT FALLS SMELTER.— W. F. M. LOCAL ENTERS CONTRACT.

J. D. Ryan, on his recent visit here, said that the time had come when it is necessary to provide more smelter facilities, and that with this end in view it had been decided by the Anaconda Copper M. Co. to practically build a new smelter at Great Falls at an estimated cost of \$2,500,000. This work will be commenced as soon as the material can be supplied and the work will be finished in about one year. In the meantime the old smelter will be operated to about its capacity, and the new plant, while occupying the ground on which the old one stands, with large additional ground, will be so constructed that the old works will be kept in commission until the new plant is ready to start. It is the intention of the Anaconda company to make the new works the most modern smelting plant in the world, as well as the most economical.

The Eastern capitalists who accompanied Mr. Ryan to this city were so much impressed with the opportunities offered for investing their capital that they became interested in projects amounting to about twelve millions of dollars, which include the erection on an up-to-date flour mill at Great Falls and the opening up of some promising iron claims which W. E. Corey, the steel magnate, pronounced of a probable value. A. J. Earling, president of the Chicago, Milwaukee & Puget Sound Railroad Co., did not have anything to say concerning the electrification of portions of the road in this state, but he did state that there would be some extensions, and that work would be commenced at once. It is believed that quite a portion of the twelve million dollars which it was stated would be spent in this state in the next twelve months will be for railroad extension, although there is no doubt the building

of the new smelter at Great Falls is included in the amount named.

The first union connected with the Western Federation of Miners to take action in regard to the entering into a contract with the Anaconda company in regard to the wages is the Great Falls Mill and Smeltermen's Union, which, by referendum vote, decided to make such a contract, notwithstanding the action of the Western Federation convention a couple of years ago in repudiating any contracts so entered into in the future. There was another vote taken on the question as to whether there should be a demand for an increase in wages, and this was carried, it being decided to ask for an increase of 50c. per day. In the course of a few days the question of a contract and the increase will be taken up with C. F. Kelley, vice-president and resident director of the Anaconda company, but no intimation can be secured as to the intention of the company in regard to the increase. While, of course, the determination of the Mill and Smeltermen to ask for the increase in wages carried by a large majority, the cordial relations existing between the men and the company are such that there is no danger of trouble.

JOPLIN, MISSOURI

RECORD PRICES FOR ZINCBLENDE CAUSE HURRIED MINING.— NOVEL MEANS OF VENTILATION.

Mention was made in the *Mining and Scientific Press*, of March 30, of the high prices for zincblende prevailing in the month of March, when the basis for lots carrying 60% metallic zinc reached \$55.50 per ton, or within \$1.50 of the record basis figure of 1905. April saw the price advanced to \$57, the 1905 record, and throughout the month prices remained unusually strong, with a healthy indication that the demand would continue good for some time to come. While the high offerings are a great boon to producers, especially those of thin sheet ground ores that cannot be mined at a profit when the demand is weak, a bad feature has developed in the tendency of the operators to produce the maximum tonnage regardless of underground conditions. As the great bulk of ore comes from comparatively shallow levels, 20 to 300 ft. in depth, the danger of surface cave-ins is ever present when precautionary measures are not observed. At the Weaver mine, on the Anderson farm, north of Carl Junction, the company, already turning out a large tonnage of high-grade concentrate, endeavored to still further increase the output by cutting into a rich pocket immediately beneath the public highway. A cave-in, that took place in ground to the surface, resulted. W. S. Brown, State Mine Inspector, was forced to notify the company to discontinue work in this drift. Mr. Brown has found similar conditions in various portions of the district. The soft pocket mines are far more troublesome than the harder sheet ground properties. As a result of the great amount of rush work now being done in order to turn out the concentrate while prices are at a record figure, the life of many properties will be materially shortened through the inability of the operators to handle much of the ground that is now being recklessly cut.

At the Morsman-Sly mine, on the Rising property, adjoining the Joplin city limits on the west, a bad air condition has been overcome by utilizing a drill-hole as a medium of ventilation. At times the gaseous condition would become so bad that miners would be hoisted unconscious from the ground. Efforts to blow fresh air into the drifts proved useless. The company started an air drift toward a shaft several hundred feet toward the west, but before this shaft could be reached it became evident that workmen could no longer stand the foul atmosphere. The drill-hole was then sunk into the air drift and this affords ample ventilation. So strong is the upward current of air at the lower end of the hole that a lighted torch, held in the draft, is immediately extinguished. This company is working a thin deposit, the mill recovery of which is less than 4%. The concentrate averages better than 61% metallic zinc.

General Mining News

ALASKA

JUNEAU

The Alaska Mexican G. M. Co. in March made a production of free gold and concentrate valued at \$57,348. Operating expense amounted to \$30,752, and construction expense to \$2310, leaving a net profit of \$24,286. The company crushed 19,215 tons of ore, which yielded an average of \$3.01. The concentrate saved amounted to about 458 tons. During the month 306 ft. of development work was done, of which, on the 1320-ft. level, 54 ft. was in an orebody assaying about \$2.66 per ton. The other work was on the 1460 and 1570-ft. levels, and through 'waste.' The stock of broken ore was increased 14,070 tons.

The Alaska United G. M. Co.'s report for March has been received in San Francisco. The Ready Bullion claim produced free gold and concentrate valued at \$50,304. Operating expense amounted to \$26,474, and construction expense to \$651, leaving a net profit for the month of \$23,179. The 700 Foot Claim produced free gold and concentrate valued at \$40,514. Deducting \$29,713 for operating and \$1173 for construction expense, the net profit for the month was \$9628. The Ready Bullion 120-stamp mill crushed 18,004 tons of ore, from which 506 tons of concentrate was saved. The 700 Foot Claim 120-stamp mill crushed 18,879 tons of ore, from which 362 tons of concentrate was saved. On the 700 Foot Claim 512 ft. of development work was done and the stock of broken ore increased 1696 tons. Of the development on the 1210-ft. level, 117 ft. was through an orebody assaying \$3.76 per ton, and, on the 1320-ft. level, 123 ft. in an orebody assaying about \$3.79 per ton. On the Ready Bullion property 96 ft. of development was done through waste. The stock of broken ore was increased 5826 tons.

ARIZONA

COCHISE COUNTY

The Shattuck-Arizona Copper Co. has decided to build a 400-ton smelter. It is reported that the smelter may be built at Douglas. Development is being rushed on the property, where a force of 60 men is employed.

MOHAVE COUNTY

It is reported that Barney McCall has discovered rich ore on his property between the Gold Hill mine and the Dandy group of claims. S. W. Mudd recently inspected the tungsten ore properties in the Big Sandy district. The O. & C. Mining & Development Co.'s mill is about ready for dropping the stamps. The company is operating the Last Chance property in the Wallapai Springs district. The Tom Reed Gold Mines Co. recently held its annual meeting. The board of directors was re-elected, with Charles Grimes as president. During the year dividends amounted to 3% on the present capitalization of the company. The dividends in some instances amounted to more than was paid for the stock, it is said. There is over \$100,000 in the sinking fund.

YAVAPAI COUNTY

B. P. Miller, representing Boston investors, has bought the Big Pine M. Co.'s property in the Hassayampa district, including three patented and one unpatented claim, a mill, and other buildings. A partial payment has been made, the price being reported as \$80,000. Richard A. Parker, of Denver, will be temporarily in charge of the mine. It is reported that the Arizona State M. Co., having straightened out its financial affairs, will resume development of the Tom Boy mine, in the Castle Creek district. Mark Bradley will be in charge for the company. Work is to be resumed soon at the Lincoln property.

John Kniffen and associates of El Paso have made the first payment under the bond and lease they secured several months ago on the Apache Box Canyon gold property. It is reported that Kniffen and his associates have

transferred their interest to Boston capitalists for a consideration of \$500,000. The board of directors of the Bisbee Coalition M. Co., it is reported, recently ratified an agreement with New York capitalists who are to furnish \$500,000 for development of the property, which is in the Warren district. S. S. Badger is consulting engineer to the company. The Arizona Copper Co. has awarded a contract for two electric cranes to the Morgan Engineering Co. of Kansas City. The contracts were let at the office of Repath & McGregor. The cranes will be used at the new smelter at Clifton. A similar contract, to the same firm, has been awarded for a crane for the Calumet & Arizona plant at Douglas. Each of the cranes is to have a main hoist capacity of 40 tons and an auxiliary hoist capacity of 15 tons.

YUMA COUNTY

D. T. Jackson and associates, who recently purchased the mill near Daggett, in the Copper Basin district, have acquired a Huntington mill. C. W. Mitchell and J. H. Watson have found a large deposit of milling-grade ore on the Arizona Empire property, it is reported.

CALIFORNIA

AMADOR COUNTY

The East Eureka 20-stamp mill was started May 2. It is reported that enough ore has been uncovered to run the mill for two years. L. Pommstone is in charge of the property.

Press despatches state that B. W. Pitts has discovered rich ore 100 ft. north of the old Mountain King shaft.

CALAVERAS COUNTY

(Special Correspondence.)—An important find has been made at the Tulloch mine, three miles south of Angels Camp. A shoot, understood to be 14 in. wide, has been opened 180 ft. from the surface. Samples are reported to assay \$100 to \$2000 per ton. The property is operated under bond by Joseph F. Curtis and associates of Los Angeles. The Lightner 3-compartment shaft is rapidly nearing the 900-ft. point. With the gaining of the 1000-ft. level, lateral development will be started. Owners of the Hamby announce that all indebtedness has been settled and that operation will be shortly resumed. The erection of a mill at the Big Fraction, Rail Road Flat district, is under way. Rich ore has been recently opened. With the exception of driving for the Yellow Metal ore-shoot, no work is being done at the North Star mine. The shoot in the western part of that estate, and its intersection at depth would prove important.

Angels Camp, May 5.

Work has been resumed at the Petticoat mine, Rail Road Flat, after a shut-down of two years. A. T. Copley, of Los Angeles, is manager, and J. E. King superintendent of the property. The former indebtedness has been wiped out. Sinking will be started soon at both the Kennedy and Afterthought shafts. It is announced that F. W. Boire will build a modern plant at the Boire Brothers' placer mine. The Star mill, at Angels, has closed.

John L. Whitney has obtained a bond on the Rising Star placer mine at Central Hill from D. Cassinelli.

INYO COUNTY

(Special Correspondence.)—The Skidoo Mines Co. in March produced bullion valued at \$11,957, and cyanide bullion valued at \$2451; a total output of \$14,408. Development and operation for the month cost \$9542, leaving a net profit of \$4866. The company treated 1175 tons of ore.

Skidoo, May 6.

KERN COUNTY

J. B. Thornton, representing the Western Asbestos Co. of Chicago, recently inspected several tracts of land near Randsburg, said to have rich deposits of asbestos. He is quoted as saying that within a year the company would start operation in that district.

LOS ANGELES COUNTY

A meeting of the Mining Engineers Society of Southern

California has been called for the evening of May 14 at the Sierra Madre club rooms. F. J. H. Merrill, chairman of the committee on organization, has requested those unable to come to notify him.

MODOC COUNTY

(Special Correspondence.)—Men are flocking into the High Grade district, and it is evident the place will be given much attention during the summer months. Deep snow still prevents exploration or development to any extent, but a number of deals have been made recently. Mining men from outside districts, particularly those from Colorado, appear to think well of the ore showings, but little actual work has been accomplished, and everything is in a prospect stage. J. F. Bassler, operating a lease on the Big Four, reports opening a shoot two feet wide, in an adit. The ore is said to average about \$90 per ton. The Modoc Mines Co., composed of Chicago people, reports a 3-ft. vein in the 35-ft. shaft. About 18 in. is said to average \$40 per ton. Narrow seams of quartz in the Sunshine contain ore ranging from low-grade up to ore assaying \$1000 per ton. It should be remembered that only small quantities of ore have been produced, not tons. The Conniemac Mining & Realty Co., of Denver, has taken a lease and bond on the Huckleberry group, adjoining the Big Four. It is rumored that San Francisco and Oakland people have decided to start development of the Seven Lakes claims on Yellow mountain. J. F. Branley is manager. Harry Millpaugh and J. A. Adams, of San Francisco, announce they have secured an option on two-thirds of the Fort Bidwell Consolidated property. It is stated that work will start as soon as weather permits. Numerous deals of minor importance have been announced, but it is doubtful if much money has changed hands, although capitalists are showing eagerness to secure options. It is expected that weather conditions will permit mining throughout the district early in June. It is stated that cyanidation will be required in most instances.

Fort Bidwell, May 4.

PLACER COUNTY

Serious shortage of water is feared by miners here. The Big Dipper company is about to start sinking a shaft to bedrock, about 60 ft. below the surface. E. H. Lowell is foreman of the property.

TUOLUMNE COUNTY

Daniel Jones has taken an option on the Laura and North Star properties, near Tuolumne, from James M. Ashton of Tacoma, Washington. The price announced is \$22,500.

COLORADO

DENVER COUNTY

Press reports from Denver state that sand assaying \$45.80 per ton was removed from the excavation for the Oxford hotel addition in that city. An unusually deep sub-basement was dug for the structure, which, it is said, rests on the old Cherry creek bed.

GUNNISON COUNTY

Placer miners are unusually active in Washington gulch. The gold is fine, and few nuggets have been found, but it is rumored that the results obtained would make a dredge profitable.

LAKE COUNTY

Recent development on the Fairplay property, Adelaide Park district, is said to have proved the orebody to be 40 ft. wide, and the largest in that part of the district. The Winthrop G. M. Co. has been incorporated to operate in the Big and Little English gulches. The company has about 1000 acres in all under lease. J. M. Moore, of Leadville, is president of the company.

OURAY COUNTY

It is reported that rich deposits of nitrate and phosphate have been discovered near Ouray.

SAN MIGUEL COUNTY

The Nellie mill, according to recent reports, will be ready

for operation in a short time. Part of the plant was caved in by a snow-slide. George Hall, superintendent, is having the mill repaired. The Wild Boy Huntington mill and tables will be erected soon. The plant was purchased late last season. The property will be operated throughout the summer. The Lake Superior-Ophir company, operating the old Calumet-Telluride property, has intersected the Black Cloud vein at a depth of 1500 ft. The ore is of milling grade and contains some free gold. The mill will be started soon, under the management of Charles H. Sandquist. James Belisle and C. H. and Richard McKeever have started development of property purchased from H. J. Turner, in the Long Park district. The property is said to have uranium-vanadium ore.

TELLER COUNTY (CRIPPLE CREEK)

In April the mills of the Cripple Creek district treated about 30,000 tons of low-grade ore, averaging \$3.50 per ton, taken from the tailing dumps. The Rogers brothers have started treatment of tailing at the Isabella Mines Co.

CONCENTRATOR ROOM AT STRATTON'S INDEPENDENCE.

mill. The Blue Flag company's mill is being overhauled. The Happy Year M. Co. is planning to build a plant for low-grade ore. Edwin Gaylord, lessee at the Jo Dandy mine, Bull hill, is moving the Jerry Johnson mill to the Jo Dandy.

The production of the Cripple Creek district in April was as follows:

Plant.	Tonnage.	Gross value.
Golden Cycle (Colorado City).....	33,000	\$660,000
Portland (Colorado City).....	10,000	220,000
Smelters (Denver and Pueblo).....	3,750	243,750
Portland (Cripple Creek district)...	13,440	44,083
Stratton's Independence	10,491	35,038
Colburn Mill (Ajax mine).....	4,000	12,000
Wild Horse	1,100	3,520
Cavanaugh mill (Jo Dandy mine)...	400	2,000
Total	76,181	\$1,220,391

NEVADA

ELKO COUNTY

A small force of men is at work on the Bluster and working in ore in three faeces. The snow is melting rapidly and several companies are preparing to start work, over in the Crater section, early in May. There is a prospect that the Bourne or Fletcher-Clark debts may be settled, but affairs at the Pavlak look very uncertain. There is plenty of ore in the Bourne, and the small mill can be easily remodeled to effect a profitable saving. The big mill at the Pavlak is of little account for any purpose. It would probably be cheaper to ignore it entirely and put up a modern five-stamp mill, if any attempt at all should be made to start up there again.

ESMERALDA COUNTY

(Special Correspondence.)—The estimated production of the Goldfield Con. Mines Co. for April was 28,317 tons of

ore, valued at \$580,000. Operating expenses amounted to \$195,000, leaving a net profit of \$385,000. The company on April 30 paid its regular quarterly dividend of 30c. per share, and customary extra dividend of 20c. per share.

The company's report of production and earnings for the first quarter of 1912 is as follows:

Month.	Tons treated.	Value recovery.	Net operating Costs.	realization.
January	28,870	\$696,875	\$225,735	\$471,140
February	27,641	693,212	205,950	487,261
March (approx)	30,132	685,000	200,000	485,000
Total	86,643	\$2,075,087	\$631,685	\$1,443,401

Goldfield, May 4.

The Goldfield Granite Mountain M. Co., in the Gold Mountain district, has cut a 6-in. seam of ore assaying \$95 to \$130 gold per ton. The Jumbo Extension company is conducting tests at the Nevada Goldfield 20-stamp mill. If the tests are satisfactory the Jumbo Extension may secure the mill for treating exclusively its own ore.

LINCOLN COUNTY

Supplementing the Prince Consolidated report recently published, George C. Kirby has issued the following statement regarding ore developed in the mine: tons, 870,893; gold, 0.01 oz.; silver, 2.86 oz.; lead, 3.95%; zinc, 4.7%; iron, 31.30%; manganese, 12.96%; lime, 4.95%; silica, 14.26%. Excess iron-manganese and lime over silica, 34.95 per cent.

In a report to the Home Run management, E. R. Zalinsky says that a 90-ft. incline shaft has been driven. On the 40-ft. level an orebody several inches to 17 ft. wide, and assaying 15 to 30% copper, he reports, has been opened. The ore is chrysocolla and malaehite and contains some silver. A plan for development is outlined in the report, which it is said the company will follow.

NYE COUNTY

It is reported that silver-sulphide ore assaying \$300 to \$1000 per ton was found recently in the cross-cut on the 535-ft. level. The production of the Tonopah district for the week ended May 4 is summarized by the *Tonopah Miner* as follows:

The Tonopah M. Co. shipped 3200 tons, the Tonopah-Belmont 2050 tons, the Montana Tonopah 1052 tons, the Tonopah Extension 1012 tons, the West End 845 tons, and the MacNamara 458 tons, making the total production for the week 8617 tons, valued at \$215,425.

STOREY COUNTY

A decision of the Supreme Court last Saturday reversed the ruling of the trial court in the Silver Peak case, which is decided in favor of the company. The lower court ruled that B. A. Gamble, F. S. Chadbourn, and the heirs of J. B. Wright were entitled to enter the property for the purpose of deciding whether or not they would exercise a right to purchase an eleven-sixteenths share in the property under an option given by the Silver Peak Mines Co. to J. L. Hanchett in September 1895, which, with an extension, expired August 1, 1896. The plaintiffs, Gamble and Chadbourn, contended that Hanchett merely was the agent of a partnership between Gamble, Chadbourn, and J. B. Wright, and that he took the option for this partnership, but later claimed it for himself.

The Pittsburg Silver Peak 120-stamp mill, according to W. A. Bradley, general manager for the company, is treating about 15,500 tons of ore per month. The ore is low grade, but the saving is excellent.

WHITE PINE COUNTY

The Nevada Con. Copper Co.'s report for the quarter ended March 31, shows a production by the company of 17,578,450 lb. copper, of which 6,309,228 lb. was produced in January, 4,888,790 lb. in February, and 6,380,432 lb. was produced in March. The low production in February was due to the shortage of water caused by the dry season and insufficient snowfall. Additional reservoirs, as has been noted before, will be provided to prevent a recurrence of

such conditions. The ore treated amounted to 728,572 tons, of which 75,547 tons was mined by underground methods at the Veteran. The ore averaged 1.85% copper. After deducting \$145,762 paid to the Steptoe plant for depreciation, \$125,754 for 'ore extinguishment,' and paying the tenth quarterly dividend, amounting to \$749,773, the undivided profit account showed a net credit of \$212,479. The net surplus for the quarter was \$483,995, and the gross income from mine, investment, and other sources was \$1,233,768. A change was made in including the 'ore extinguishment' item in the quarterly report, instead of at the end of the year. The old practice caused misunderstanding among some of the stockholders. The company has entered into a contract permitting the Steptoe Valley S. & M. Co. to concentrate the sulphide ore of the Gironx Con. Mines Company.

NEW MEXICO

SOCORRO COUNTY

The Ernestine M. Co.'s first ten-day clean-up in April yielded 8470 oz. of gold and silver bullion and five tons of high-grade concentrate. During the week 742 tons of ore was treated. The Oaks Co. reports a total of 35 ft. of development in the Pacific mine during the week, from which 42 tons of ore was sent to the Deadwood mill. Work continues in the main drainage and transportation adit. An excess of 5000 tons was treated by the Socorro Mines in March. About 93% of the gross value of the ore is being recovered by concentration and cyanidation. The Treasure M. & R. Co. reports that the mill on White-water creek treated 400 tons during the week.

OKLAHOMA

ROGERS COUNTY

The Bartlesville Zinc Co., Collinsville, will add to its present plant one 100-kw. turbo-generator set, one 25-kw. motor generator set, two 50-hp. motors, one 25-hp. motor, one 75-hp. motor, and a switchboard, furnished by the General Electric Company.

OREGON

BAKER COUNTY

Development will be resumed soon at the Blue Mountain M. Co.'s property in the Cable Cove district. The property includes the Last Chance and Baby McKee groups of claims. Snow, at last reports, is delaying the starting of the work. Calvin Haines will be manager.

SOUTH DAKOTA

LAWRENCE COUNTY

The Homestake M. Co. surface plant soon will be operated exclusively by electricity from the \$1,250,000 hydro-electric plant recently completed. The Amicus mill now is being operated by electricity. The hydro-electric plant has a capacity of 10,000 hp., and is said to be practically paid for, from current earnings, as the company has a cash surplus of about \$50,000. The mills affected by the change of power are arranged in 24 units of 10 stamps each. Each unit will be operated by 25 hp., and an auxiliary plant will be equipped with machinery taken from the mills using electricity. The company will dispense with coal, and it is believed that the plant will pay for itself in eight years. For the seven months ended December 1, 1911, the company's profit showed a rate of \$11 per share of outstanding stock.

UTAH

JUAB COUNTY

According to a prearranged plan, a drift on the 500-ft. level of the Crown Point mine has penetrated the Colorado company's property, crossing the dividing line last week. The drift still is in line formation, but it is expected that the work will open ore later on. The Black Jack hoist is in commission, and prospecting is being done on the 300 and 600-ft. levels. E. R. Higgenson is in charge of the Black Jack property. In the week ended May 3, ore shipments from the Tintic district amounted to 164 cars.

SALT LAKE COUNTY

Foreign laborers at the A. S. & R. Co. plant at Murray walked out May 1, demanding a raise of 25c. per day. They were receiving \$1.75. C. W. Whitley, general manager, was East. J. M. Bidwell, acting manager, stated that the company did not feel justified in meeting the demands. Whether or not American laborers at the plant are in sympathy with the foreigners is not known.

SUMMIT COUNTY

During April 284 cars of ore was shipped from the Park City district, the tonnage being 9766. The companies shipping were the Silver King Coalition, 3747 tons; the Daly West, 3266; the Daly-Judge, 2437; Grasselli Chemical Co., 334; Ontario lessees, 138; Daly company, 22; and Charles Moore, 22 tons.

TOOELE COUNTY

E. P. Mathewson has submitted plans for an additional lead furnace for the smelter at Tooele to the officials of the International company at New York. The plant, although designed for a capacity of 250 tons of ore, is treating about 300 tons per day.

WASHINGTON

FERRY COUNTY

The North Washington Power & Reduction Co. will build a power line from Grand Forks, British Columbia, to Republic, according to J. L. Harper, general manager, who has just returned from the East. He also said the cyanide plant will be enlarged to a capacity of 5000 tons per day. The Chicago Title & Trust Co. has been named trustee for a bond issue of \$1,600,000 recently authorized by the power company. The mill will start within a few days. James W. Turner, manager for the San Poil Consolidated M. Co., announced in Spokane that the new mill at Republic will be in operation within two weeks. He said that recent developments in the Republic district have been important. The discovery of free-milling gold ore on the Knob Hill property was particularly noteworthy. The details of the find have not been made public. Workmen on the San Poil mine are still mining high-grade ore, he said. The incline shaft in the Surprise mine, which is being sunk below the 600-ft. level, has reached a depth of 80 ft., where was cut the highest grade ore which has been found on the property.

WASHINGTON, D. C.

(Telegraphic Correspondence.)—An attempt to abolish the mints at San Francisco, New Orleans, and Carson, and the assay offices at Boise, Deadwood, Helena, Seattle, and Salt Lake City, was defeated in the House today by a vote of 92 to 61.

Washington, May 9.

CANADA

ONTARIO

(Special Correspondence.)—The Dome mill extraction continues to give good satisfaction. Two shipments per month from the clean-ups of the amalgam and one shipment per month from the clean-up of the cyanide mill are expected. About three-quarters of a mile of driving and cross-cutting has been done on the Dome property. The deepest shaft is 220 ft. deep and No. 2 shaft is being sunk to the 300-ft. level. Two more diamond-drills have been taken from the Dome property, leaving one at work to do what testing may be required in the future. Over thirty holes have been drilled on the Dome orebody, so far, and the hole now being put down in the eastern end of the property, near the Dome Extension, is in remarkably rich ore. The West Dome is driving on a promising orebody reached by cross-cutting from the No. 3 shaft at the 100-ft. level. The Dome Extension is cross-cutting N.35°W. to cut the main vein at the 200-ft. level. This cross-cut has been driven 330 ft., while the cross-cut northeast to cut the large orebody in No. 4 shaft is in 250 ft. The North Dome is connecting the two shafts at the 50-ft. level. About 20 veins have been un-

covered on the Success property, and show fairly high assays in places. Ernest Yorke has taken charge of the Hughes, vice Mowry Bates resigned. The managements of several properties are taking special precautions to guard against fire. A customs house has been opened at Golden City, with G. S. Rogers as custom's officer. There is prospect of an early resumption of mining at the Pearl Lake, as matters are in a fair way for an early and satisfactory adjustment. The refinancing of the Wa-wai-a-tin Falls Power plan, by D. Lorne McGibbon and associates, has infused new life into that district.

Petitions are being circulated asking the Ontario Provincial Government that Mountjoy or Foolham river be made navigable to where it enters McArthur, thus providing a good boat route to the southern part of the mining division, where some discoveries of free gold have been made. Large deposits of nickeliferous pyrrhotite have been discovered in Bartlett and Geikie townships, west of McArthur, and also east of Frederickhouse lake, north-east of Poreupine.

South Poreupine, May 2.

The Crown Chartered company has made the final payment on the Davidson property in the Poreupine district. The property includes five claims. The main shaft is down 215 ft., and a station has been cut at the 200-ft. level.

Plans for the Swastika mill are in the hands of the management for consideration. The plant will cost about \$25,000. The Lucky Cross company, in the Swastika district, has cut a 12-ft. orebody in its east adit. The Nipissing company, on April 29, shipped to New York 23 bars of bullion, containing 27,020 oz. silver, valued at \$16,381. On April 27 the same company shipped 23 bars, containing 25,945 oz., valued at \$15,761.

MEXICO

DURANGO

(Special Correspondence.)—The Compania Minera y Exploradora de Ventanas, S. A., property has suffered from the revolution. Rebels from Sinaloa, where a state of anarchy is reported, have attacked Ventanas twice, and in both cases were repulsed by a small garrison. The company has machinery there which it is unable to transport to the mines on account of bandits in the mountains.

Practically all of the isolated properties in this state are closed, owing to difficulty in transportation. Railroad and mail communication recently was restored. Much inconvenience has been experienced on account of the cutting of telegraph wires. Anti-foreign feeling, fostered by the recent note by the United States Government, is high. Strict censorship prevents knowledge here of the situation in Chihuahua. Even if federal troops gain a victory soon, it is improbable that much good will result, as there are not enough soldiers available to crush the mountain bandits. Unless a speedy settlement is effected there will be little planting of crops.

Durango, April 29.

The Tominil M. Co., Ltd., in March earned a profit of £1270, from 1012 tons of ore crushed. While the property has not been damaged, and no interruption of work in the mine or mill is expected, the presence of bands of armed men nearby, and numerous depredations have made operation difficult. Costs in March amounted to about 50s. per ton, as against the usual rate of £1 per ton. The yield was 81s. per ton, while the gross value of the ore reserves is estimated at 42s. 7d. per ton.

JAPAN

(Special Correspondence.)—The Japan Petroleum Oil Co. has purchased from the International Oil Co. its lease at Hachinosana Hokkaido. One well is yielding 30 to 40 bbl. per day from a depth of 1030 ft. A small refinery is to be built at Raisatsu. The drilling machinery recently purchased in California has been sent to Echigo and a well will be drilled near Kashiwazaki.

Kashiwazaki, April 29.

Personal

Professional men are invited to send news of their engagements and travels. Such news is interesting to friends.

W. A. SCOTT is at Seattle.

W. C. HOWARD has returned from Mexico.

REESE LLEWELLYN was here during the week.

S. E. BRETHERTON has gone to Shasta county.

F. L. LOWELL has returned from Amador county.

J. E. CALLAHAN, of Ely, Nevada, is in San Francisco.

J. F. GURNEY is at San Francisco on his way to Colombia.

H. W. REETH has sailed for Europe from Auburn, Massachusetts.

CHARLES JANIN was expected to arrive in New York yesterday.

D. H. STEINMETZ has returned to San Francisco from Sonora.

RICKETTS & BANKS have removed to 80 Maiden Lane, New York.

W. H. ALDRIDGE was at Globe recently and has returned to Los Angeles.

W. DE L. BENEDICT has removed his office to 19 Cedar street, New York.

E. Z. BURNS is in Colorado on professional business and will go to Nevada.

J. R. FARRELL is at Battle Mountain, Nevada, preparing to reopen the Dean mine.

W. L. COBB is developing the Pleasant View drift mine near Comptonville, California.

H. V. WINCHELL has returned to Minneapolis, and expects to leave soon for Europe.

C. W. PURINGTON has been appointed chief engineer for the Pioneer Company of Siberia, Ltd.

J. R. FINLAY will deliver the commencement address at the Missouri School of Mines, May 31.

F. H. PROBERT is at Salt Lake City to consult with D. C. JACKLING in regard to Ray Central affairs.

BRADLEY STOUGHTON, L. D. HUNTOON, and A. H. ELLIOTT have opened offices at 165 Broadway, New York.

J. C. WARD, general manager for Edgar Allen & Co., Ltd., of Sheffield, was in San Francisco, on his way to Japan.

E. M. WILKINSON has returned from the Pis Pis district of Nicaragua, where he spent the past winter in examination work.

A. NEWMAN and R. L. BEALS have opened offices as consulting mining and metallurgical engineers in the Mills building, San Francisco.

Obituary

SABUROSUKE MITSUI, who died at his villa at Kamakura, Japan, April 5, was the head of the Mitsui Mining Co., the mining branch of Mitsui & Co., Ltd. The family is one that can be traced back to Takayasu Mitsui, a feudal lord of the sixteenth century, and it was one of the great commercial institutions of Japan even before the restoration. Saburosuke Mitsui was born in 1850 and was a clerk in the Kyoto office of the firm when the shogunate was abolished. Like many other young Japanese of that time, he threw in his lot with the progressives. He spent two years in the United States studying and returned to take a position in the mining department, of which he subsequently became the head. Under his administration the Miike colliery and other mines belonging to the company were equipped with the most modern machinery, and a large and efficient organization was built up. He was one of the men who contributed to the making of modern Japan and of the little but influential group that formed a link between his home country and America.

Company Reports

CHINO COPPER CO.

The properties of this New Mexican porphyry copper mine were described in the *Mining and Scientific Press*, March 30. Below is given the income account for the year ended December 31 last, and covering the first period of production. Further details regarding the operation of the company will be printed later.

INCOME ACCOUNT FOR THE YEAR ENDED DECEMBER 31, 1911

Operating revenue:	
Copper produced (986,375 lb. at 13.3c.).....	\$131,231.77
Operating expenses:	
Mining	\$ 7,632.55
Freight on ore	4,546.40
Milling	53,171.79
Treatment, refining, and freight....	31,319.25
Selling commission	1,312.32
	97,982.31
Net operating profit.....	\$ 33,249.46
Net miscellaneous income, dividends, rentals, royalties, etc.	85,223.29
Net income for year.....	\$118,472.75
SUMMARY OF PROFIT AND LOSS	
Balance to credit of profit and loss, Dec. 31, 1910..	\$165,972.97
Net income for year ended Dec. 31, 1911 (as above)	118,472.75
Balance, Dec. 31, 1911.....	\$284,445.72

UTAH COPPER CO.

Details of the operation of this company for the past year, as reported by D. C. Jackling, general manager, are given on another page of this issue. During the year 93,514,419 lb. of copper was produced at a cost of 7.85c. per pound, yielding a net profit of \$6,237,928. The ore reserves were increased by exploration to a total of 301,500,000 tons of fully and partly developed ore of an average copper content of 1.532%. The extraction of copper was increased from 20.51 lb. per ton to 21.03 lb. per ton. Below is presented the income account for the year ended December 31, 1911.

INCOME ACCOUNT FOR THE YEAR ENDED DECEMBER 31, 1911

Operating revenue:	
Copper produced (93,514,419 lb. at 12.6163c.)	\$11,826,164.58
Gold produced (40,202,916 oz. at \$20)	804,058.32
Silver produced (366,906.96 oz. at 53.3c.)	195,564.36
Miscellaneous	165.56
	\$12,825,952.82
*Operating expenses:	
Mining	\$1,529,275.62
Stripping ore	351,060.07
Mine development	216,125.51
Total for mining and development	\$2,096,461.20
Freight on ore	\$1,440,748.55
Milling	1,950,988.83
Treatment, refining, and freight	2,717,592.85
Selling commission	118,261.61
	8,324,053.07
Net operating profit.....	\$4,501,899.75
Miscellaneous income:	
Dividends on investments.....	\$1,720,750.00
Interest received	3,124.83
Rentals	32,293.28
Royalties on lessees ore.....	10,827.00
	1,766,995.11
Total income	\$6,268,894.86
Less:	
Interest paid	30,966.42
Net profits for year.....	\$6,237,928.44
UNDIVIDED PROFITS	
Balance to credit undivided profits, December 31, 1910	\$3,696,539.06
Net profit for year ended December 31, 1911 (as above)	6,237,928.44
Total	\$9,934,467.50
Dividends paid during year.....	\$4,703,022.00
Part of prepaid ore account (stripping expense) written off.....	2,500,000.00
	7,203,022.00
Balance, December 31, 1911.....	\$2,731,445.50

*Note.—The operating expenses shown include the sum of \$149,440.83 paid in taxes.

RAY CONSOLIDATED COPPER CO.

The essential features of the first year's work of this company, which is one of the Arizona porphyry copper mines, were presented last week. The properties of the company were described in detail in the *Mining and Scientific Press*, September 2, 1911. The profit and loss account for the year ended December 31, last, is given below, and further details of operations will be printed later.

Operating revenue:

Copper produced (14,935,047 lb., at 13.08c.)	\$1,953,627.06
Silver produced (1,733,534 oz., at 53.46c.)	926.71
	\$1,954,553.77

Operating expenses:

Mining	\$556,397.68
Freight on ore.....	247,856.12
Milling	405,166.49
Freight, treatment, and refining.....	564,019.57
Selling commission	19,706.10

NEVADA CONSOLIDATED COPPER CO.

This company has capital stock outstanding to the value of \$9,996,700 and bonds to the value of \$500. The net profit for the 15 months ended December 31, 1911, was \$4,336,217. Of this, \$633,347 was written off for the initial cost of ore extracted during the period. The deferred charge for stripping in excess of the amount charged to operating expenses was \$938,249. During the 15-months period 3,338,242 tons of ore of an average copper content of 1.80% was milled, with an average extraction of 67.59%, yielding 78,541,270 lb. copper at an average cost per pound of 6.97c. Five quarterly dividends amounting to \$3,746,894 were paid. The profit and loss account for the 15 months ended December 31, 1911, is as follows:

Gross revenue:

Copper produced (78,541,270 lb. at 12.50c.)	\$9,818,261.98
Gold and silver produced.....	595,185.09
	\$10,413,447.07

Operating expenses:

Mining, including proportion of stripping expense	\$1,072,121.76
Freight on ore	893,310.50
Milling	1,531,859.17
Smelting	1,485,634.90
Rent of Steptoe plant (including depreciation)	1,467,610.24
Freight and refining	1,145,810.90
Selling commission	97,144.70
	7,693,492.17

Net operating profit

Miscellaneous income:

Dividends on investments	\$1,537,160.02
Interest on bonds	62,500.00
Interest and discount	14,211.44
Rents and miscellaneous income	10,260.81
	1,624,162.27

Total income

Less maintenance Cumberland-Ely property

Net profit for the 15 months available for dividends

Mica is being mined in the Charleston district, near Westport, New Zealand, by a private syndicate, whose headquarters are in Christchurch. The first shipment of a ton was recently made to London, and a further consignment will be ready soon. It is understood that there is an increased demand for mica for electrical and other purposes, and it is calculated that the quality and accessibility of the Charleston product will make mica-mining there profitable. The mica deposits at Charleston are fairly extensive.

JAPAN'S consumption of Chilean nitrate increased from 5892 tons in 1907 to 28,000 tons in 1911, and it is expected that 40,000 tons will be required for 1912.

Production of Copper in 1911

By B. S. BUTLER

*The smelter production of primary copper in the United States in 1911 was 1,097,232,749 lb., as compared with 1,080,159,509 lb. in 1910, an increase of about 1.5%. The production for 1911 is the largest in the history of the industry. In the following table the production for 1911 is apportioned to the states in which the copper was mined. The total is made up of the fine copper content of blister produced and of the smelter output of ingot and anode copper from Michigan. The production of 1910 is given for comparison. This report is based on returns from every known company which treated copper-bearing material in 1911.

PRODUCTION OF COPPER IN THE UNITED STATES IN
1910 AND 1911

(Smelter output, in pounds fine.)

	1910.	1911.
Alaska	4,311,026	22,314,889
Arizona	297,250,538	303,202,532
California	45,760,200	35,835,651
Colorado	9,307,497	9,791,861
Georgia	724
Idaho	6,877,515	4,514,116
Maryland	23,555
Michigan	221,462,984	218,185,236
Missouri	640,411
Montana	283,078,473	271,814,491
Nevada	64,494,640	65,561,015
New Hampshire	12,409
New Mexico	3,784,609	2,860,400
North Carolina	181,263	13,699
Oregon	22,022	125,943

Utah	125,185,455	142,340,215
Vermont	1,935
Virginia	105,313
Washington	65,021	195,503
Wyoming	217,127	130,499
Undistributed	603,570	44,645
	1,080,159,509	1,097,232,749

*Includes Missouri.

Refined Copper.—The total production of new refined copper in 1911 was 1,433,875,026 lb. This was the largest output in the history of the industry, exceeding that of 1910 by 11,835,893 lb. The production of electrolytic, Lake, casting, and pig copper from primary sources and the production of secondary copper by the regular refining plants in 1911 is shown in the following table:

PRODUCTION OF PRIMARY AND SECONDARY COPPER, 1911,
IN POUNDS

	PRIMARY	
	1911.	
	Domestic.	Foreign.
Electrolytic	823,507,764	332,604,223
Lake	218,185,236
Casting	22,977,534
Pig	36,600,269
	1,101,270,803	332,604,223
	1,433,875,026	

*Advance statement by the U. S. Geological Survey.

SECONDARY

Electrolytic	19,093,622
Casting	8,803,105
Total secondary	27,896,727
Total output	1,461,771,753

The figures for Lake copper include the Michigan copper that was electrolytically treated. In addition to the secondary material treated by the regular refining companies, plants treating secondary material exclusively, produced a total of 186,311,000¹ lb. of copper as copper and in brass and other alloys of copper, making a total production of 214,207,727 lb. from secondary sources. Of this, at least 62,000,000 lb. was produced by remelting clean scrap produced in the process of manufacture of copper and brass articles. If the output of plants treating purely secondary material is added to the production of the regular refining companies, the contribution of the United States to the world's supply of copper for 1911 is found to be 1,648,-082,753 pounds.

Stocks.—Returns from all smelting and refining companies show that the following stocks of electrolytic, Lake, casting, and pig copper were on hand at the beginning and end of the year 1911, in pounds:

January 1, 1911.....	122,803,656
January 1, 1912.....	88,372,195

Decrease during 1911..... 34,431,461

In addition to the stocks of refined copper, there were reported as at the smelters, in transit to the refineries, and at the refineries, blister copper and material in process of refining to the amount of 219,864,749 lb January 1, 1912, as compared with 245,218,530 lb. January 1, 1911.

Consumption.—The apparent consumption of refined new copper in the United States in 1911 was about 681,700,000 lb. In 1910 it was about 732,400,000 lb. The method employed in determining the quantity of copper retained for domestic consumption is shown in the following table. It does not take into consideration stocks of copper held by consumers.

APPARENT DOMESTIC CONSUMPTION OF REFINED NEW
COPPER IN 1910 AND 1911, IN POUNDS

	1910. *	1911.
Total refinery output of new copper	1,422,039,135	1,433,875,026
Stock at beginning of year....	141,486,244	122,803,656
Total available supply.....	1,563,525,379	1,556,678,682
Refined copper exported.....	*708,316,543	*786,553,208
Stocks at end of year.....	122,803,656	88,372,195

Total withdrawn from supply 831,120,199 874,925,403
Apparent consumption 732,405,180 †681,753,279

*Exports of pigs, bars, ingots, plates, etc., reported by the Bureau of Statistics.

†The apparent consumption as here calculated differs considerably from the domestic deliveries reported by the Copper Producers' Association. This difference is accounted for chiefly by the difference in export figures as reported by the Bureau of Statistics and the Copper Producers' Association, owing to the fact that the two sets of export figures are based on a slightly different period and therefore may show considerable difference for any one year.

If to the 681,700,000 lb. of new refined copper is added the 214,207,000 lb. of secondary copper and copper in alloys produced during the year, it is found that a total of 895,-900,000 lb. of new and old copper was available for domestic consumption. A more comprehensive report is being prepared and will soon be published. Copies can be obtained upon request to the Director of the U. S. Geological Survey.

¹Subject to revision.

Concentrates

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

IN the Guerrero mill at Pachuca, tailing from the Wilfley tables is conveyed in a launder having a 3% grade. It is necessary to mechanically shake the launder in order to get a regular flow.

TO cement iron to stone make a putty-like substance of finely ground brick-dust stirred into melted rosin. Set the iron into the hole in the stone and pour the hot putty around it. Push bits of heated brick into the mass, smooth off, and let cool. This cement is not affected by the weather and does not injure the iron, but holds it firmly.

FEEDING conveyor-belts by means of a steam-shovel involves the difficulty of converting an intermittent into a continuous supply. If the belt be large enough, 42 to 48 inches, the difficulty is easily met, and in the coal-yards 5-yard clam-shell buckets deliver to conveyor-belts and work smoothly. With wet sticky material of irregular size there would be more trouble, and yet in certain situations the combination of belt and shovel is better than the usual system of tracks and cars.

ASOLDERING fluid which will not rust or corrode the soldered parts can be made by dissolving as much zinc in hydrochloric acid as the acid will take up, and then adding water, glycerine, and alcohol. To one part of glycerine add one part of alcohol and one part of water, then add two parts of the zinc chloride solution. This fluid can be used for all kinds of soldering and has been found especially desirable for greasy or dirty work as well as for soldering to iron. It is claimed that the glycerine prevents rust, which plays havoc with soldering fluids which contain hydrochloric acid.

LOSS of cattle because of pollution of streams by cyanide waste is occasionally reported, but facts are hard to obtain. At the El Tigre mine when the mill first started there was trouble from this source, but the cause of the difficulty was promptly detected and a remedy applied. Such loss is not apt to occur in the course of regular work. It is only where, because of leakage or some temporary accident, solutions of unusual strength get away, that there is complaint. In the case in point, the company was protected against damage suits through owning absolutely the land on both sides of the stream for fourteen miles below the mill.

PUMPS often give trouble because of an unequal pressure within the steam-chest acting on the area of the steam-valve, or the valve-stem. As the valve-stem extends through only one side of the steam-chest there is a constant tendency to blow it out. To overcome this trouble the use of a coil spring between the bracket and collar has been recommended. This spring should be given sufficient tension to counterbalance the action of the steam acting on the area of the valve-stem. While the action of the steam is to force the valve-stem out of the chest, the spring forces it in again and, therefore, the forces are neutralized and the valve-stem stays where it is left by the tappet arm.

WOOD-FIRED reverberatory furnaces of large size have been used in Australia for many years, according to Edgar Hall. At the Silverspur mine, Queensland, they have been used in sizes ranging from 17 to 40 ft. from bridge-wall to skinning door, 40 ft. being the largest size now in use. Furnaces wider than 15 ft. have not been used at Silverspur, but at Burranga, N. S. W., a furnace 50 ft. long is used. No difficulty is experienced in heating these furnaces with wood; no other fuel is used, and a longer furnace could be built if conditions should make it desirable to do so. The ore is not easy to smelt, and the matte fall is only 3.5%. The 40-ft. furnace smelts 40 tons per 24 hours, nearly all of which has to be slagged.

Decisions Relating to Mining

Specially reported for the MINING AND SCIENTIFIC PRESS.

MINING CLAIMS—ADVERSE POSSESSION

The claimant to mineral lands of the United States who has been in their open, exclusive, adverse possession for a continuous period equal to that required by the local statute of limitations governing adverse possession of real estate, is relieved of the necessity of making proof of posting and recording a notice of location, but he must be able to show, in a quiet-title suit, that he has complied with the requirements of a discovery and annual assessment work.

Humphreys v. Idaho Gold Mines Development Co., (Idaho) 120 Pacific, 823. January 8, 1912.

PLACER MINES—ENJOINING DISCHARGE OF DEBRIS

A person who has located and is operating a placer mine along or across a stream of water, is entitled to a reasonable and proper channel and the water. However, such miner has no legal right to dump his mining debris into the channel or stream and allow it to be carried down by the water to the land of a lower proprietor, or to fill up the channel to the injury of such proprietor. In order to avoid such threatened injury, the miners may be enjoined from continuing to so discharge such debris.

Provitt v. Bailey, (Oregon) 121 Pacific, 861. March 19, 1912.

LODE CLAIMS—DISCOVERY AND EXPLORATORY WORK

One who, not having actual possession of mineral land of the United States, seeks to recover it from another, must show a prior valid location. Such a location can be held valid only where the locator has complied with the requirements of the state law as to discovery work, and has, within the time by law allowed, made a discovery of a "vein or deposit of rock in place." He cannot leave his claim, allow another person to make a location thereon, and then eject the junior locator by completing his own discovery work and rendering nugatory the work already done by the junior locator.

Ferris v. McNally, (Montana) 121 Pacific, 889. February 15, 1912.

MINERS LIENS—NOTICE OF NON-RESPONSIBILITY

Where, as in Colorado, it is provided that in order to relieve a mine-owner from liability for mechanics' liens filed by employees of his lessee or vendee, notices of non-responsibility for labor or materials furnished at the request of such lessee or vendee must be posted on the claim, a mine-owner cannot escape such liability by merely providing in a working contract of sale that the purchaser shall post such notices. If the purchaser fails to do so, the laborers or material-men may enforce their liens upon the claim in the manner authorized by law.

Pike v. Empfield, (Colorado) 120 Pacific, 1055. January 8, 1912.

STATUTE OF LIMITATIONS—MEASURE OF DAMAGES

Where an underground trespass was committed and ore secretly and fraudulently taken from another's property, the statute of limitations runs from the date that the true owner of the ore discovered the trespass and not from the date at which it was committed. The measure of damages in such a case is the value of the ore in the mine at the date of taking, with interest from that date, where the taking was without oppression, fraud, or malice. If there was oppression, fraud, or malice in the taking, then the value of the ore as finally mined and milled would be the measure, the cost of mining and milling being added as punitive or exemplary damages.

Lightner Mining Co. v. Lane et al. (California) 120 Pacific, 771. January 22, 1912.

EDITORIAL

THE first annual report of the Director of the United States Bureau of Mines is a consistent record of good work, justifying the hopes of those who insisted on the establishment of the Bureau.

SEVERAL parties of prospectors have left San Francisco recently for Bolivia, where placers north of La Paz are attracting attention. One party of American miners cleaned up 240 ounces of gold from a single bar last season, and reported colors for some distance higher up the stream.

STIRRING up race prejudice to carry elections is a disreputable kind of politics that usually indicates loss of hope. In California the attempt to make capital for Mr. Taft by exploiting Mr. Roosevelt's message relative to the Japanese at the time of the school troubles in San Francisco was a reminder of back-woods politics in the South.

HIGH GRADE, the new name for an old district in Modoc county, California, continues to attract prospectors and promoters despite the fact that the ground is covered with snow and fully staked. For reasons given in our editorial April 6, and by Mr. W. H. Storms elsewhere, we see no reason as yet for getting excited. There are small erratic streaks of rich ore in the district and, as always, a stampede into such an area may result in the discovery of important deposits. We hope it may in this case, but till the snow melts there will be more money made, and lost, in trading locations than in prospecting.

JAPANESE authorities promulgated April 10 a new customs tariff for Korea. According to the new schedule, metal manufactures and hardware in general must pay a duty of 7½ per cent *ad valorem* based on the value of the articles at the port of entry. An exception is made in favor of tools, instruments, machinery, explosives, and chemicals necessary to the digging or mining of gold, silver, and copper which are imported by persons engaged in mining work for their own use, provided that such articles are recognized as reasonable by the customs officials. Owing to the large American mining interests in Korea this exception is especially important.

OUR New York correspondent, in writing of the Miami Copper Company recently, stated that the annual report did not show the cost of copper laid down in New York. This is an error, the figure, 9.103 cents per pound, being given in the table showing the copper account. The price 5.80 cents used in Mr. Gottsberger's report is merely the cost at the mine less the credit for silver and house rentals. Mr. J. Parke Channing, in discussing the report, calls attention to the fact that the percentage of extraction, 73.37, is not a true index of what may be expected when the interior and unoxidized mass of ore is reached. The mining cost, \$1.21 per ton, may also be expected to be reduced after the top layer of ore has been removed and regular caving begun.

AUSTRALIANS are already beginning to plan for an exposition at Perth to signalize the completion of their first transeontinental railway, construction of which has just begun. It is especially appropriate that the celebration be held at the western end of the line, since the coming of the rails will make Fremantle the first port of call for European boats and establish a new Golden Gate in the south seas.

A UNIQUE company recently organized is the Research Corporation, with offices at 63 Wall street, New York, and of which the following well known gentlemen are directors: Messrs. William L. Dudley, T. Coleman du Pont, Frederick A. Goetze, Elon H. Hooker, Hennen Jennings, Charles Kirchhoff, Benjamin B. Lawrence, Arthur D. Little, John B. Pine, Lloyd N. Scott, Charles A. Stone, James J. Storrow, Elihu Thomson, Charles D. Walcott, and Mark S. Reardon. The project is primarily due to the unselfish initiative of Mr. F. G. Cottrell, ably seconded by those named, and others. These gentlemen have joined together and propose to devote time and money to the development by research and commercial methods of inventions to which patent rights are to be acquired by purchase or otherwise. The peculiar feature of the enterprise is that there can be no profit to any one concerned, all funds realized being dedicated to "the advancement and extension of technical and scientific investigation" under the auspices of the Smithsonian Institution and such other scientific or educational institutions as the directors may select. In other words, the plan involves endowment of research through the profits of invention, and it is big with possibilities. Already valuable patent rights have been assigned to the corporation, and others have been offered. Apparently inventors are as willing to aid the enterprise as are the business men concerned, and the whole project affords a grateful contrast to the mercenary side of human nature that is too frequently in evidence.

RUSSIA proposes to close to prospecting the "manifestly gold-bearing" lands that belong to the Crown and to dispose of them by auction. There is no objection to this in principle, but it is doubtful whether in Russia the territory has been sufficiently prospected to warrant such action. Unless the lands are manifestly gold bearing in fact, no one can afford to bid, and also, unless the Government provide other means for stimulating prospecting, development will stop. On another page Mr. T. F. Van Wagenen takes strong ground against any interference with the prospector, who, he states, does not exist in Mexico and Canada. The rapid growth and manifest prosperity of the mineral industry in these countries, and especially in Canada, seems to indicate that there are other methods of stimulating the finding of ore deposits, than the particular ones adopted in the United States. Mr. Van Wagenen thinks that development in both Canada and Mexico has been checked by the failure to give a fee title and the absence of extralateral rights. This opinion in the matter is entitled to the greatest respect; but prospecting is equally inactive in many parts of the United States under conditions exactly the reverse, and mineral development has, on the whole, been as rapid in the Joplin, Missouri, district as anywhere—and there are not only no extralateral rights, but high royalties must be paid. The problem of securing economical development of the mineral wealth of a country is by no means simple. If the experience of the world counts for anything, there are various methods of approach, and it may be that no method is inherently bad or in itself good, that the choice of system must be determined by the particular conditions obtaining

at any given time and place. Pragmatism may well be a working rule as well as a closet philosophy.

THE FIGHT made at Washington to convert the San Francisco mint into a mere assay office calls attention to one of the peculiarities in the rules of the House of Representatives, one which gives large power to the ruling clique of the moment in the Appropriations Committee. A bill framed by this committee is based upon the work of sub-committees, and neither the recommendation of a sub-committee nor of the committee is made public, even to members of the House not on the committee, until the bill as a whole is printed and laid before the House. Since bills covering hundreds of items are rushed through in a few days, at times a few hours, it practically results that the continuation, expansion, or cutting down, of any branch of the public service is decided in 'star chamber' session of three to five men. The opportunity for reversing the action of a committee is so limited as practically not to exist in most instances.

An International Dictionary

A correspondent writes to suggest that an enormous field for translators of American textbooks on technical subjects lies open in the Spanish-American countries to the south of us. That we have been remiss in cultivating our Latin friends in the field of ideas as well as of trade, is indubitable; of this we are often reminded. Part of the blame unquestionably lies in American preoccupation with home affairs; we are so tremendously busy trying to comprehend ourselves and do all that is necessary to our own rapid expansion, with its necessary readjustments, that there is little time and less opportunity for cultivating our foreign friends. But part of the difficulty is a fundamental one that is commonly overlooked. Many persons suppose that to translate a book into a foreign language requires only a working knowledge of the language and a few weeks work with a lexicon. Nothing could be further from the truth, and in many cases it is almost as easy to write a new book as to make a really good translation of a foreign text. Part of this is due to the fact that in many cases no exact synonyms exist for words of a foreign language, and the situation of the translator is much like that of the pianist who, playing by ear, vainly sought to pick out an accompaniment for a singer whose notes were of uncertain pitch. Giving up in despair, he remarked, "It is no use; I've tried it on the white keys and on the black keys—it must be in the cracks."

Even more serious in the translation of technical works is the fact that often the ideas represented do not exist in the foreign country, so that it is impossible to attempt translation without first creating a vocabulary. This is not so true of Spanish, but is especially the case with Oriental languages, where translation involves the introduction of so many new words as to present almost insuperable difficulties. If the resourceful translator invents words the natural result is that several words become current for the same thing and the final outcome is compound confusion. In such cases, clearly the situation must be met from within: if the people of any country wish to assimilate the knowledge and culture of another they must do so gradually by building up an equivalent knowledge and culture of their own. Learning must be acquired in homeopathic doses, not *en bloc*. The schools and universities must be leaders in the movement, seconded by journalism. Translation of technical English into Spanish is possible and may be made profitable. The preparation of a really good technological dictionary covering all the principal languages, something equally needed, would be the greatest possible aid to inter-

national intellectual coöperation. The latter venture holds out so little hope of monetary profit and involves so great preparatory effort and expense that it cannot be expected to result from private initiative. But in these days it should be possible to secure a gift of sufficient funds to undertake a task of this magnitude and importance, which would serve as a worthy memorial. We commend, to wealthy citizens who desire to be of service, the compilation of an international dictionary as a more effective agency for securing international comprehension and good-will than the creation of any number of peace prizes.

Recent Copper Smelting

We are fortunate enough to be able to present this week a brief account of copper smelting practice at the plant of the Compagnie du Boleo, written by a well-informed engineer. This is interesting, both because the company does not follow the common American custom of allowing engineers free access to the plant and its records, and because the working conditions are so exceptional. The slag analysis, given by our correspondent, is unusual in its composition, though not in its character. Assuming that the alumina acts entirely as a base, and that manganese is equivalent to iron (the statement of manganese as MnO_2 evidently being merely for analytical purposes), and computing the oxygen ratios, we find SiO_2 , 27.55; Al_2O_3 , 8.45; $FeO \cdot MnO$, 2.67; CaO , 3.14; or an oxygen ratio of acid to base of 27.55 to 14.26. The slag is evidently slightly more basic than bisilicate, and since Mr. H. O. Hoffman, in his admirable work upon the formation temperatures of silicates, has shown that the substitution of MnO for FeO slightly raises the temperature of slag formation, while Al_2O_3 , when substituted for FeO and CaO , lowers the temperature of slag formation until three-eighths of those bases has been replaced, and then raises it rapidly, it is not remarkable that the furnaces run with a high temperature in the zone of fusion, a considerable degree of fluidity, and the rapid separation of the high specific gravity matte. Slags high in manganese are not uncommon, and Mr. J. A. Church has recorded his experience in smelting silver-lead concentrate in Arizona, with the formation of a satisfactory slag containing over 40 per cent manganese. Our correspondent employs a loose expression common among metallurgists in speaking of slag containing a high percentage of SiO_2 , as being necessarily an acid slag. Percentages depend upon weight, while the acid or basic character of the slag depends upon the molecular ratio of the acid to the basic constituents. If the basic constituents have small atomic weights the same percentage of silica which represents an acid slag would, with bases of large atomic weights, represent a very basic slag.

The use of narrow long furnaces at this plant may be contrasted with recent development of smelting practice at the Great Falls plant of the Anaconda Copper Mining Company, where Messrs. A. E. Wheeler, superintendent, and M. W. Kreeji, metallurgist, under the management of Mr. C. W. Goodale, have developed furnaces 84 inches wide, the necessary blast penetration being secured, as in the iron blast-furnace, by so proportioning the cross-section of the furnace as to obtain a throttling action near the top of the shaft, thus causing the blast to spread throughout the smelting zone by pressure, rather than by depending on the initial velocity of the blast to secure penetration. The use of this design has permitted a lowering of the blast-pressure to 20 or 25 ounces, with campaigns a week long without barring off crusts at the tuyeres. The wide furnace offers less radiating surface than a long one, and where it is operated so that barring down is minimized the resulting economy in heat requirement is worth

securing, and construction costs are lessened.

Even more notable are the converter records which have been made at the Great Falls plant. The converters now in use are of the Anaconda type, 12 feet in diameter and provided with 26 tuyeres, using blast at 11 or 12 pounds per square inch. These are lined with magnesia brick, and one converter has made over 7000 tons of copper without relining, while an earlier type of converter, of the same size but with only 15 tuyeres, has been in continuous operation since March 9, 1910, and has made over 12,000 tons of copper from a 28.9 per cent copper matte. Including cold seconds, about one ton of cold material has been handled per ton of matte converted, so that this converter has treated some 60,000 tons of material with the one lining. This is a record of which the able metallurgists who have made it may well be proud, and technical men generally may share in their pride, since it is undoubtedly to a considerable degree secured by the employment of a staff of technically trained young men as investigators to study every operation and to plot records and collect data, so that each day's experience may serve as an infallible guide to the solution of the problems of tomorrow. There is no waste so regrettable as the waste of experience, and employment of trained minds is cheaper in the end than the cut and try method with structural steel, labor, fuel, and valuable ore. We hope later to be able to present details of some of the results thus secured, and we take this opportunity to congratulate the metallurgists concerned as highly upon the methods employed as upon the results obtained.

The Oldest Fossils

Archean rocks were at one time supposed to represent the original crust of the earth, and in consonance with then prevalent ideas were considered to be necessarily of igneous origin. When sedimentary rocks were found in what had been considered to be Archean, the Algonkian system was proposed, to include all the rocks lying upon the original crust and antedating the oldest fossiliferous strata. In time the Algonkian came to include a number of series of rocks occupying a definite place in the stratigraphic column, and in time fossils were found in some of the Algonkian rocks, notably the Belt series of Montana. Also indubitable sedimentaries had been discovered in the redefined Archean, and it became evident that a *a priori* definition of pre-Cambrian formations would lead to constant readjustment of boundary lines and endless confusion. Accordingly the attempt to adhere to the old definitions has been tacitly abandoned, and in America, at least, Archean and Algonkian have come to mean certain systems of ancient rocks classified on ordinary stratigraphic grounds. If this conclusion had not already been reached it would have been forced by the recently announced discovery by Mr. A. C. Lawson of fossils in the Steeprock series of western Ontario. This series, first described by Mr. H. L. Smyth, lies certainly in the Archean. It includes a massive limestone that is in part "almost an aggregate of fossils." Mr. C. D. Walcott, who has studied the new forms, finds them to be closely related to the sponges, and states that if the stratigraphic position were not well determined he would be inclined to consider the fossils as of lower Cambrian age. This recalls the fact that in the Lake Superior region, so far as paleontologic evidence goes, the great series of Algonkian and Archean rocks are only certainly known to be older than the upper Cambrian. The various changes in the definition of Archean in that region suggests the advisability of one of the geologists interested paraphrasing Mr. Champ Clark's campaign song about the 'dawg.'

Types of Porphyry Copper Deposits

By W. L. TOVOTE

The present prominence of the porphyritic copper deposits as factors in the world's copper market has brought forth an ample and varied literature. Globe, Clifton-Morenci, Bisbee, and Bingham have been described in monographs of the United States Geological Survey. Other information is scattered through the professional publications of the past few years. While much material has been collected, it has not so far been attempted to classify these deposits, point out their common prominent characteristics, and draw conclusions from the observed facts in some as to possibilities in others.

Though knowing that there are better men than myself to attempt this, I wish to try to develop certain deductions from the geological conditions as they appear to me, and hope this may give rise to discussion and establish the possibilities of these deposits and their future.

The porphyritic copper deposits may be divided into four main types, not because these are considered as genetically different, but only to bring out their chief characteristics, show their common features, and prove that all of them are only different facies of one group of deposits. Their genesis is uniform and their variations are due only to development in different country rocks and to different depths of exposure. The four types are:

1. Braden, Chile, and Nacozari, Sonora; volcanic and semi-volcanic facies.
2. Morenci, Arizona, and Bingham, Utah, contact and metasomatic deposits; disseminated deposits limited to the intrusive.
3. Miami and Ray, Arizona, disseminated deposits, mainly in the rock intruded.
4. Bisbee, Arizona, irregular bodies in limestone.

This subdivision is not meant to be a classification, as I consider all these types as belonging to one group. Most of them, in fact, grade into each other, and in several districts two or more of these types are represented, one of which gave rise to local operations. Another may hold the main interest at present, and to a third the future may belong. I could perhaps add to these four types still a fifth one, namely, the type of vein formation represented by the Old Dominion of Globe, but since other processes helped to shape this deposit, I shall only casually mention it.

1a. Braden.—Braden has been described by Pope Yeatman. According to his description and information kindly given, the deposit is an extinct volcano. Rhyolitic lavas and tuffs fill an old crater in andesite country rock. The andesite is brecciated and partly re-cemented, as are also the tuffs, by the acidic eruptive. The ore (chalcopyrite, pyrite, and zincblende and their secondary derivatives) occurs at the contact between andesite and tuff, preferably in the former, and also in a central channel in the tuff itself. Exceptional and not recurring in the other deposits is tourmaline, but that is not surprising in view of the exceptionally strong fumarolic action.

1b. Nacozari.—Nacozari is similar to Braden, except that the volcanic action was probably less forceful and instantaneous. Here, as there, an andesitic lava-flow is intruded by rhyolite. But the rhyolite probably followed a pre-existing fault-plane, along which it formed roughly elliptical columns. One of these is the Pilaes, that practically forms the Nacozari mine. A second one is the San Juan, where ore has been proved, and still more is indicated by promising outcrops. The rhyolite is brecciated, but tuff has not been developed. Chalcopyrite and pyrite, cementing and replacing this breccia, constitute the ore. The ore-shoots occur at the contact between andesite and rhyolite, but preferably in the latter. There are also central orebodies, roughly columnar in shape, in the central part of the rhyolite.

2. Morenci and Bingham.—The ore is connected with intrusion of acidic porphyries; monzonite and granite-porphry at Morenci, monzonite at Bingham. It occurs at the contact of porphyry and sediments, preferably in limestone and shale, in the immediate vicinity of porphyry dikes and sills, and also disseminated through the mass of the porphyry. While the porphyry at Bingham is uniformly mineralized and shows only slightly increased content where fissuring is more pronounced, the ore is more concentrated along intersecting systems of veins or lodes at Morenci. The mass of the porphyry shows also a general mineralization away from the lodes, but this is usually of too low a grade to constitute ore. Furthermore, the workable ore deposits are localized in the vicinity of great east-west faults, that apparently antedate the mineralization, even if they do not antedate the porphyry intrusion. One of these faults, the Coronado, constitutes a tremendous vein deposit, of related character, away from the porphyry. The ores are chalcopyrite, pyrite, and zincblende and their secondary derivatives in the contact deposits, while in the porphyry is found pyrite replaced or partly replaced by chalcocite.

3. Miami and Ray.—These are contact zones between granite-porphyries and crystalline schists. These schists are similar to porphyries in chemical composition. The ore is pyrite and chalcocite, corresponding to the Bingham-Morenci porphyry ore, and occurs both in schist and granite, but preferably in the schist.

4. Bisbee.—The Bisbee ore deposit is practically the same as the contact deposits at Morenci and Bingham. The ore occurs as irregular masses in sediments directly connected with porphyry sills and dikes, in the Shattuck porphyry dike, and in the contact zone of the main intrusive mass of Sacramento hill. The primary ore is chalcopyrite and pyrite. Chalcocite has been found in the central part of the Sacramento hill porphyry stock.

To sum up the common properties of these different ore deposits:

1. Porphyry.—All are connected with porphyry intrusions. The porphyry is apparently everywhere the source of the metals and the cause of their deposition. All the porphyries are acidic or ultra-acidic. All are rather recent intrusions, ranging from late Cretaceous to Tertiary.

2. Metallic Contents.—Pyrite and chalcopyrite (sometimes also zincblende) are the only primary sulphides, disregarding Miami and Ray.

3. Distribution.—All show an outer or contact zone of ore and another one in the central part of the intrusive, again disregarding Miami and Ray.

4. Silicification.—All show, besides the deposition of metallic sulphides, a more or less intense silicification both in the contact zone and in the intrusive.

At Braden and Nacozari practically only primary ores occur. There is some secondary ore developed, but that is of very little importance. An insignificant chalcocite horizon at Nacozari is underlain by a lean pyrite zone, which soon gives way to normal chalcopyrite ore. Braden has been opened for a vertical distance of 2500 ft., Nacozari for over 1000 ft. from the top of the ore in both cases. Nacozari is proving richer in depth. Braden shows no indication of impoverishment. As both deposits contain, below the slight oxidized zone, exclusively primary sulphides, due to a porphyry intrusion from deep-seated magmatic sources, the ore may be expected to go down to the *ewige tiefe*. At the same time, this is, I presume, an indication of the deep facies and the primary type of all porphyritic copper deposits.

I have neglected to mention the secondary orebodies of Bisbee. These were of almost unparalleled richness and firmly established the district. But secondary alterations

are always to some extent due to local and casual conditions; they have practically no bearing upon genetic classification and are a dominant factor in economic considerations only if the primary ore is of no commercial value. But at Bisbee primary ore is gaining in importance every day, and the time may not be so far distant when it will be the main factor. Of course, there are some primary orebodies that are not of commercial grade and others that are workable only on account of incipient secondary enrichment, represented by a penetration or coating of the primary sulphides by chalcocite. But some orebodies have been and are mined only on their strength of their primary constituents, pyrite and chalcopyrite.

How Bisbee deposits will do in depth is left to future development to decide. There has been a more intense differentiation and rearrangement of the metallic masses than in most other places. Besides, the ore deposits in the limestone represent only one phase of the ore-depositing activity of the porphyry, and the second part of the mineralizing action of the porphyry has been thus far only established, not tested. I have intentionally refrained from mentioning bornite among the primary sulphides. Bornite forms, with chalcopyrite, extremely rich orebodies, especially in the Sacramento hill contact zone. But while some authorities regard bornite as a primary contact mineral, others consider it as purely secondary. I might point out lastly that, as at Bisbee, where the orebodies follow the intricate system of porphyry dikes, and especially sills, through limestone, at Morenci also the orebodies of this type seem practically limited to porphyry dikes that show a pronounced tendency to form sills between the sediments, as seen in the Longfellow and Detroit-Manganese Blue mines and on a smaller scale in the West-Thompson.

The disseminated chalcocite deposits in the porphyries and schists are only secondary as far as their ore reserves are now computed. They form a limited belt, seldom more than 300 ft. thick and frequently considerably less. They are usually overlain by an entirely barren capping from 35 to over 1000 ft. thick; the Southwestern Miami, with over 1000 ft. of cap-rock, is probably the deepest, but I do not know whether that is due to natural conditions or later overthrusts. Exceptionally there are preserved in this oxidized capping some secondary copper bodies, and in Morenci some pyrite also. At the bottom of the chalcocite zone there is an abrupt change to lean pyrite and sometimes marcasite. The chalcocite zone, as shown at Morenci, is richest near its upper limit, where it consists of almost pure chalcocite. Farther down the chalcocite contains increasing amounts of pyrite.

GENESIS OF THE PORPHYRITIC COPPER DEPOSITS

The ore deposition can be divided in two processes that blend into each other:

1. Contact action.
2. Eruptive after-effects.

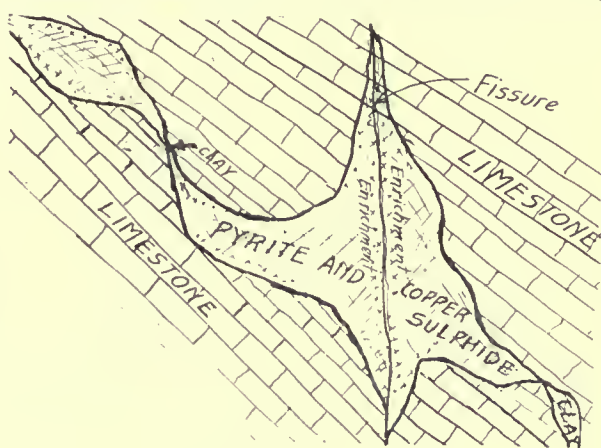

1. *Contact action.* In the copper deposits of the contact zone more or less pronounced contact action occurs in limestone country rock. There appears recrystallization (marble), silicification, and development of heavy silicates such as garnet (andradite and grossularite), tremolite, diopside, sillimanite, and others. The metallic sulphides are intergrown with these silicates and indicate sometimes contemporaneous development. In country rock other than limestone silicification and recrystallization occur as a rule. Sometimes epidote appears, especially in shale. Hence it follows that the intrusive contained excessive amounts of silica and heavy metals such as iron, copper, and zinc. These were more or less concentrated in the contact zone, where a rapid chemical exchange, perhaps induced by the water contained in the intruded rocks, caused their deposition. The metallic sulphides formed were pyrite, chalcopyrite, and zincblende.

2. *Eruptive after-effects.* While the upper part of the intrusive was probably drained of its metallic contents by this process, the same accessory substances remained dissolved in the lower, still molten, part of the magma and in the deep-seated hearth of the intrusion. Therefore a

continuance of deposition was possible and is proved by the later silicification and dissemination of metallic sulphides throughout the intrusive itself. Contraction fissures are filled by quartz that contained fluid, gaseous, and solid inclusions, probably mostly sodium-chloride, carbon dioxide, and iron and titanium oxides. Metallic sulphides penetrate the cooling rock as disseminations or as fissure fillings.

In Braden and Nacozari the sulphides fill central channels in the intrusive, channels that gave rise to hot waters or vapors, or both. The mineralization is the same as in both places. And why should it not be so, since the condition in the volcanic vent remained probably the same, even if the action retracted more and more toward its source. Of course, in these two cases everything is reduced to the simplest type, and at the same time is on a compact and small scale. The diameter of the Braden volcano is only 4000 ft. and the long axis of the Pilares ellipse is about 2500 ft. But even in great intrusive masses, where the porphyry body is measured in miles, the occurrences should be on similar lines, even if modified.

Since in Braden and Nacozari the mineralization remained the same throughout both phases of the ore-depositing activity, why should the eruptive after-effect change

IDEAL SECTION AT BISBEE.

suddenly from chalcopyrite and pyrite to lean pyrite in the other porphyritic deposits? Assuming that it did not, and that the after-action deposited chalcopyrite, as in the contact mineralization, then oxidation would cause a breaking up of the chalcopyrite into the chalcocite and pyrite molecules, disregarding the transition stages as sulphates and so on. Pyrite would migrate farther down than the chalcocite, as the latter is able to replace the former in descending reactions.

An extended repetition of this process would produce in the end a more or less solid chalcocite horizon and below it one of nearly solid pyrite. The pyrite might ultimately be concentrated to such a degree that, according to the law of mass action, it might force the copper molecule out of the remaining chalcopyrite and in that way produce a zone of secondary impoverishment below the zone of secondary enrichment. The sudden and abrupt change from chalcocite ore to lean pyrite and marcasite I regard as a zone of this character.

Proof that commercial ore reappears below the lean pyrite is found in Nacozari. Indications in the same direction, even if still very indistinct, begin to appear in the vein deposit of the Old Dominion. I regard the complete disappearance of the zinc content of the Morenci porphyry, that apparently once constituted a considerable part of the metallic mineralization there, and in the fresh porphyry exceeds the copper content, as a further proof of this. Therefore I believe that at Morenci primary sulphides will not be reached before passing through a zone of sphalerite enrichment. Naturally I do not suppose that these primary sulphides could constitute commercial ore, if they occurred thinly disseminated, as for instance in the Ray-Miami contact zone, but I presume that these primary sulphides will occur mainly in trunk channels, fissure veins, or columnar ore-shoots.

The Prospector and the Mining Law

By T. F. VAN WAGENEN

As the agitation for a revision of the mining law is being revived in certain quarters, it may not be amiss to examine the subject from a point of view somewhat different from that usually taken by the mining engineer or investor, and yet one which perhaps is worthy of very careful consideration.

The two principal ends to be secured by a mining law may be stated as follows: (1) to induce exploration and discovery by the prospector, so that the mineral resources of the country may become known; and (2) to give such reasonable legal security in the matter of titles as will encourage the investment of capital in the business of mining. As mines cannot be worked until they are discovered, it is plain that the occupation of the prospector is a fundamental one. Affairs must be so arranged that there are inducements for him to go out into the field and explore. What must these inducements be? I list them as follows:

1. He must be able to acquire title to a discovery at a very small cash outlay, for he is generally a man of small means.

2. The method of initiating title must be extremely simple, for he rarely possesses business habits or clerical ability.

3. His claim, when staked, must possess merits merely as a surface area, in addition to those it may be found to have later on as a mine, to attract a buyer, for the real prospector is only a finder and seller, and never a developer.

Consider the nature of the occupation of prospecting. It must not be confused with that of the claim locator or miner. The prospector is a pioneer pure and simple, a natural wanderer over the face of the earth, a genial and valuable variety of the genus tramp and hobo. Not one in a thousand of the class has any reserve funds, possess more than the rudiments of an education in the ordinary sense of the word, or habits of thrift. They could not follow the business if the conditions were otherwise, for it is one requiring a temperament at once careless of the future, and yet highly optimistic. Men of such characteristics are the only ones who will go out into the hills on long tramps, and examine them minutely for indications of mineral wealth. Nearly all known mines have been found by them, or by accident. Can an instance be cited of a discovery by a mining engineer or geologist, or by a business man of any kind? How absurd then it is to penalize the absolutely necessary occupation of the prospector by requiring him to take out a licence before starting on his summer tour of exploration, as is done in all countries except Spanish America and the United States, or to make the process of location one requiring anything but the simplest acts.

Again, remembering that the sole ambition of the prospector is to sell his claim on its *undeveloped* merits, how necessary it is that this claim should possess speculative attraction in itself, in addition to the lure of a promising outcrop. This special feature is provided by the theory of extralateral rights; which, coupled with free prospecting privileges, and extremely simple processes of initiating title, are the distinctive features of the American mining law, a law which has caused those parts of the continent where it is in force to become, in a half century, the best explored and the most broadly active mining region on the globe. Enacted by Congress more by accident than by foresight, yet an everlasting credit to the sterling common sense of the man most concerned in its adoption (W. M. Stewart, senator from Nevada), it embodies the three principles that are absolutely necessary for the establishment and maintenance of this class of prospectors. In fact, the prospector did not exist until this law came into being. The very name of the occupation is American, and cannot be found in any dictionary of the English language published prior to the year 1850. The prospector himself, as we know him, is not found outside of the region where that law is in

force. There can be no reasonable warrant therefore for the abrogation of its peculiar features until it is clearly evident that the country has been thoroughly explored, and all its mineral resources discovered. Of course no one will consider this condition to have yet been reached.

The value to the prospector of extralateral rights is simply this. Having made a discovery of an outcrop more or less promising as the case may be, and covered it to the best of his ability with one claim, the title to which he has acquired at very low cash cost, and by processes within the ability of even a total illiterate, he has something that he can sell, to provide the means to continue his work. Why? Because, if the outcrop is well marked, the buyer acquires in the act of transfer the right to follow it downward indefinitely, no matter where it goes. The seller is not compelled to locate one or more adjoining claims at large additional cost to himself (and with faked discovery shafts) to protect his dip. All he needs to cover is the outcrop, and if the buyer is not satisfied that this has been properly done, there is nothing to prevent him from making as many more locations as he thinks wise. All this is very obvious when the subject is considered from the prospector's point of view. That the position taken is a correct one seems to me to be confirmed by examining the history of mining districts the world over. In the western United States and Alaska, where the American law applies, there are thousands of prospectors in the field continuously, moving southward or into the lowlands in the fall and winter, and northward or into the highlands in the spring and summer. But when the international boundaries are reached in either direction, where the American law gives place to that of Mexican or Canadian, they stop, as if at a dead line. I have wandered through the former country for the better parts of five years, from the Rio Grande to the Isthmus of Tehuantepec, and have never yet seen or heard of an individual of the class. British America may be searched from Labrador to the Pacific with little better results. There was a time when the province of British Columbia had an apex law, and while it was in force the rugged region hummed with explorers. When it was repealed they faded away like snow before a chinook. In Alaska, buried in snow and ice during nine months of the year, the prospector is in evidence everywhere. Across the boundary in the Yukon Territory of the Dominion, under even more favorable climatic conditions, he is conspicuously absent. Consider the effect of the line that separates New Mexico from Texas. West of it the American law prevails and explorers are abundant. East of it the Texas state law governs, with square locations and no extralateral rights, and though there are numerous well known and promising mineral areas which were discovered before the exact position of this line was known, yet you will be unable to find a prospector in the field. In fact the situation in this respect is so discouraging in the Lone Star state that its legislature has had under consideration for several sessions the payment of bonuses for new discoveries, and the offer of other inducements to attract the class of men it needs to search over its vast unoccupied and unproductive areas.

Take the case of Africa, a continent rich in minerals, as proved by the innumerable ancient workings existing. When Egypt was in its prime great quantities of gold came from the Abyssinian highlands and the Rhodesian plateau. In the days of the Carthaginians and Romans the Atlas mountain chain was the source of much silver and lead. Anterior perhaps to both of these the great mineral field on the Congo Zambesi divide was known and worked by the natives. Yet in all this vast region, from the Mediterranean to the Cape, much of which is now far more accessible than was our own West in the days of 1850-60, not a prospector exists, and none have existed in modern times except in the province of Rhodesia. Here, because it was thrown open as a mineral field under regulations suggested by an American engineer, and with a law conferring extralateral rights, a number of American prospectors of the better class migrated when the country was opened. But they found themselves on arrival confronted with restrictions in exploring, and regulations for initiating and maintaining

title so burdensome, complex, and costly that in a few years all disappeared.

Consider the situation in Scandinavia, Siberia, Spain, Asia Minor, Italy, and Greece, all regions known to be rich in mineral resources, because of discoveries made by accident centuries ago when prospecting was free. All these lands have elaborate mining laws of the old-fashioned kind, yet one never hears of a new discovery, for prospectors are unknown. The laws do not provide for them. In Australia, on the other hand, the laws offer extraordinary inducements in the way of bonuses and governmental assistance to explorers, yet are without the extralateral rights feature. As a consequence, little more than the fringes of the continent have been looked over, and the type of prospector developed there is one totally different from the vigorous and independent individual known to us.

The conditions in Spanish America are equally to the point. When those lands were first occupied by Europeans, prospecting was free (as indeed it remains today), and practically no laws existed governing the initiation and maintenance of mining titles, beyond the grant of vast concession to explore, to favored individuals, who passed on these rights intact to their subordinates and followers. And no burdens were laid upon the industry beyond royalties on gross production. Under this system the tropical and semi-tropical portions of the two continents were overrun by searchers for the metals, with results that were enormously to the advantage of the whole commercial world of the day. Later, as political states were organized, Old World mining laws were placed upon the statute books, and immediately the prospector disappeared and the mining industry began to languish. Today, not a mineral explorer can be found in the field, and if we look into the history of the many wonderful mining districts that are known to exist in these territories, we find that nearly all the mines in operation are *antiguas*, and that almost no new discoveries have been made in modern times except in northern Mexico, into which, for a few seasons about thirty years ago, the American prospector ventured and remained until driven away by the complexity of the laws and the costs of maintaining the titles to the discoveries he made.

To come down from continents to localities, consider the instance of Zacatecas, a Mexican mining district first opened about the year 1540. Here there has been a recorded output in ounces of silver nearly double that of either Leadville or the Comstock to date, yet only a beginning has been made in uncovering its wealth. If the group of hills in which it lies could be picked up bodily and dropped in any one of our mountain states so as to open to the prospector under the provision of our Federal law, a stampede would ensue for the new locality that would recall the early days of Butte, Leadville, the Coeur d'Alene, Cripple Creek, Tonopah, and a host of other famous American mining camps. Within a few weeks thereafter hundreds of little prospect dumps would begin to blossom out on its hillsides, and within a few months dozens of new shafts would be started. But being where it is, it is one of the deadest of known mineral regions. The very nature of the trade of the prospector is unknown to its citizens, and no work is in progress anywhere except upon half-gutted *antiguas*. Of course, some allowance must be made for the difference between Mexicans and Anglo-Saxons, but this will not explain the difference in results. However, the true causes of the universal stagnation becomes clear as soon as one comes into actual relation with the Mexican mining law. There are those, it is true, who claim it to be the best yet devised. It surely has good points for the capitalist, and for the company that can keep the parish priest and the *jefe politico* on the pay-roll, but not, I maintain, for the prospector and the country itself.

As for the second object to be accomplished in the construction of a mining law, while our code is far from being all that it might be, I have no sympathy with those who are clamoring for the abrogation of the extralateral rights feature under the plea of securing better protection to purchasers and investors. Let the latter, in this matter, pro-

tect themselves or take the consequences of their own neglect or carelessness. That is the American way, and in this case the only right way. Who buys a piece of city or agricultural land without calling for an abstract of title and having it examined by a specialist in such documents? But mines are purchased daily without this simple precaution, and when trouble ensues the industry and the law are blamed when really the fault lies with the hasty or too enthusiastic buyer. Moreover, no investor should accept title to a mining claim without having its surface aspects as well as its underground condition passed upon by a competent mining engineer. If he reports that the apex of the deposit is not safely included within the boundaries as shown by the monuments, what more easy than to call on the vendor to file an amended location certificate, or locate additional ground along the side-line? Or for the buyer to perform these acts himself? Or, if the adjoining ground is already occupied and such precautions are impossible, the claim is plainly defective and must be frankly accepted as such or left alone. Plenty of real estate of the ordinary kind bears the label *caveat emptor* among conveyancers, yet no one blames the land laws for the fact.

Beyond question, the apex law has in the past caused much aggravating and expensive litigation. But practically all legal questions that can arise under it have by this time been settled by decisions of our highest courts, and nothing but questions of fact remain to give further trouble. These belong properly to the domain of the engineer, who should be adequately prepared to advise his client by having passed a rigid examination in mining jurisprudence at the institution where his degree was obtained. There is room for improvement in this branch of study in the curricula of all our mining schools.

Much has been written of late as to the large amount of mineral land held under possessory or patent title which is said to be unused by the owners and unobtainable by others who would be glad to develop and operate. So far as my experience goes, I have yet to find a promising claim that the owner will not sell or lease at some price, and on some terms, and generally the conditions asked were reasonable. But are there not millions of city lots and thousands of acres of agricultural land still unimproved and unused by their possessors? Of course, as a general proposition, it may be well in due time to compel the holders of real estate of all kinds either to use the land they own or pass it back to the public, but there seems to be no particular reason to expect the miner alone to lead the way in such a reform.

Some of the advocates of amendment have called attention to the fact that in a few localities the peculiar features of the law have been condemned and set aside by the miners themselves. This is true. Let it be admitted that there are some camps where, owing to very unusual geological conditions, the apex law, if enforced to the letter, would probably result in more harm than good. Leadville furnishes the best example. There many excellent apexes were developed, but upon exploration the ore zone proved to be so nearly horizontal that the prospector himself was the first to recognize the injustice of extralateral rights. Consequently, after the mineral area was well covered by locations, and after a few years of litigation to permit of a thorough understanding of the conditions, the law was quietly ignored by common consent of the entire community. By that time it had done its good work in giving the prospector his proper era of activity, and that individual had sold out and obtained his reward. The time had come to give the developer and capitalist their chance. This was done and the subject dismissed. It will be difficult to find in history a better example of the ability of the plain people of this country to do the right thing when left to themselves. The same story will doubtless be repeated if another Leadville is ever found on the continent. There may be some, however, who, in spite of such an exhibition of orderly and common-sense lawlessness, will deplore as unnecessary even the moderate amount of litigation that disturbed that camp in its early days, but after all a mining suit advertises a camp.

Prospecting Gold Placers in Korea

By J. J. MARTIN

The following description of prospecting work at the Chiksan mines, 50 miles south of Seoul, Korea, may be of interest because of the methods employed and the costs realized. This work was carried on toward the end of 1911 and early in 1912 with two Empire prospecting drills, with a view to determining the gold content of the placer ground under investigation. This ground was easy drilling compared with some other areas with which I have had experience. But notwithstanding this fact, the casing had to be driven with the ram for fully one-half of the footage drilled and the sling-chain was broken on several occasions. So that while the ground was easy drilling, inasmuch as no large boulders were found, yet it offered considerable difficulty.

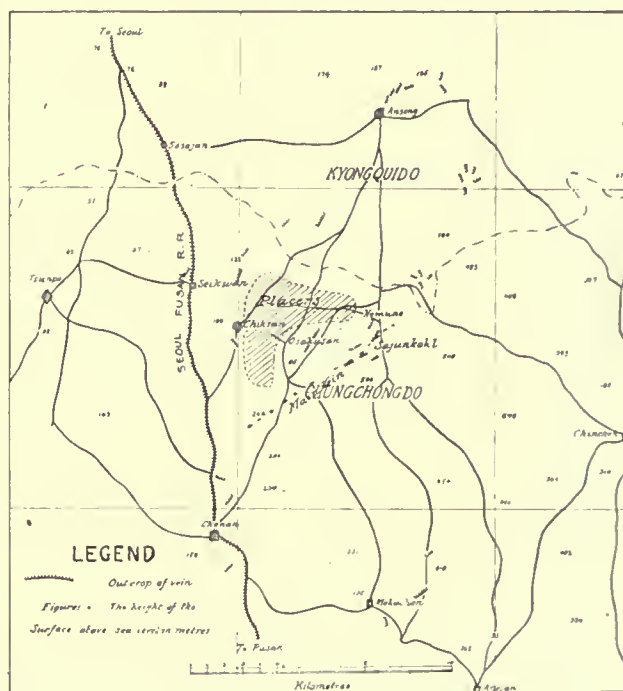

The area being drilled is in valleys where rice cultivation has been the means of clearing the land of all timber, and the surface has been made into little ponds. At the time I commenced work (November 15, 1911) a rice crop was just being cut and the water had only recently been

and only four men constantly on the platform. The extra men also facilitate the moving to the next hole, getting started more quickly than if a horse were used. I do not claim that this is the cheaper method where high-priced labor is to be employed. But it will be found inexpensive where wages do not exceed 75c. or \$1 per day for unskilled labor, as in many foreign countries.

In drilling, the principal tool used is the drilling pump. There are two to each drilling outfit with the spring drilling rig attached. The string of tools is quickly lowered without the use of the rod wrench, except that for every 15 or 20 ft. of depth as the last section of drill rod is sliding down the casing, a wrench is slipped on. By the time it has come to a stop, the next section, in the hands

MAP OF SOUTHERN KOREA.

SKETCH MAP, CHIKSAN MINES.

turned out of the fields. As a result they were simply pools of mud several inches deep. A horse could not be used for rotating the casing without laying in brush to give him a footing; and as the forest has been cut and burned for fuel in this part of Korea years ago, there was no brush available for this purpose. Labor is cheap. I secured some two-inch planks, 8 to 10 in. wide and 6 ft. long, and placed them about 3 ft. apart, radiating from where the hole was to be drilled. On top of this I placed smaller planks in a circle, two boards wide, for the coolies to walk on. Then I fastened to the platform of the drill two poles about 4 in. diameter on the large end, tapering to about 3 in. at the other end, and 100 ft. long. These were made fast to the platform on opposite sides by four clevises or yokes 4 in. wide and 5 in. long with clip and nuts underneath to fasten them firmly. These did not have to be removed in shifting the drill to the next hole. In fact, the arrangement made it quite handy to shift to the next hole, as two coolies (one ahead and one behind) simply took the poles on their shoulders with the platform swinging between. A pole of this length gives sufficient leverage to enable four or five men to rotate the casing to a depth of 25 to 30 ft. in fairly tight ground without exhausting their strength before the day is over. The rotating coolies change work with the drill-men on the platform each time a new section of casing is added. This change rests the men and the work proceeds more rapidly than with a horse

of one of the men on the platform, is in a position to screw on. Another man has the second wrench slipped over the rod to be attached, and a couple of hard jerks with the heavy wrench tightens the joint. The winch operator meantime has hoisted the string of tools, freeing the lower wrench, which, with a push of the foot, frees the rod; and the tools are on the way to the bottom of the hole in less time than it takes to tell about it. When the drill pump is hoisted, as many sections of the rod are hoisted as can be handled on the platform before disconnecting. If I am going to continue with the drill pump, I hoist four sections (20 ft. if down that depth or more) before disconnecting. When the pump is taken off to be emptied, the other pump is immediately screwed on and the tools are on the way down again almost before the filled pump has reached the washing-box. But if I am through pumping for that foot of drilling and the casing has to be rammed, I disconnect in three-section lengths (15 ft.); and these are set upright along the 2-in. pipe column of the spring drilling rig and tied there with a rope to keep them from dancing around too freely while the casing is being driven.

I never drive more than 1 ft. in depth without drilling, except in running ground, for two reasons. If in stiff ground and I have driven one foot and left a safety core from the previous drilling of 3 in. or more, I have a core of 15 in. in the casing; and continuing to drive,

there would be a tendency to force aside material that properly belongs to the sample. The other reason is that any greater depth causes the handles on the drill-rod to be too high for effective working and there is consequent loss of time in adjusting them. When bedrock is reached and is found to be soft, I drive the easing a foot or more into it, drilling and pumping 6 in. or more if the washing still shows colors. If not, I put in the vacuum-pump (not on the drill-rod, but attached to the drilling rope), and let it down with a rush so that the stem or piston will go to the bottom. Then one man takes hold of the rope and with a quick uplift of 5 ft., the suction-stem and piston is drawn up the length of the pump-barrel and creates the desired vacuum. During this time the winchman is rapidly winding up the slack with the spring drilling rig and soon the pump is up and emptied. This is repeated about three times.

Many times during the past year I have proved that the vacuum-pump removes all of the fine gold in the hole.

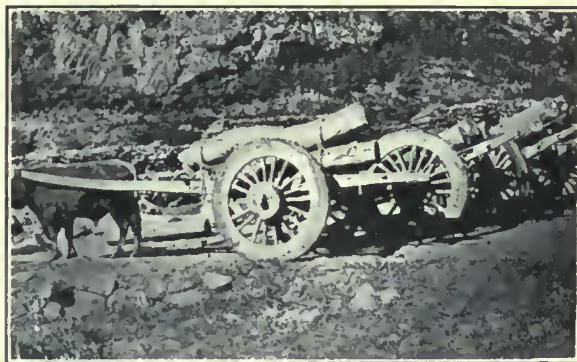

WASHING THE SAMPLE.

I have proved this by driving the easing into the bedrock (after having removed all the loose material with the vacuum-pump) until a core of 10 or 12 in. was obtained, then the easing was pulled and the core extracted and panned; seldom more than one or two fine colors are found, and many times there are none. If bedrock proves too hard to drive the easing sufficiently to pull the core, I should be quite satisfied with the vacuum-pump cleaning.

For washing the sample I made a box 18 by 26 in., with sides 6 in. high. The last 8 in. of the 26 in. is sloped to the centre, leaving an opening 8 in. wide for the sludge water to flow out into a 6-ft. sluice-box set below. This box has legs 18 in. high, which makes the right height to stand the pump on end and to dump the contents into the gold-pan, which has been punched full of holes about such as a 20-penny nail would make. This will screen off all the coarse rock. The pump is set on end in the screen pan, which protected the lower pan from being dented. Then a little pressure with the thumb on the ball-valve, or if it is too tight a few blows with a stick, will loosen the valve. With a dipper I pour water in the valve end of the pump and the contents are quickly emptied into the screen pan. The screw end of the pump is given a final dip into the washing tub to clean any sand off the threads. With another dipper of water added to the screen pan (which is raised an inch or so to allow about a half inch of water in the bottom), a few quick shakes will pass all the fine material with the gold into the lower pan. But care should be taken to look over the coarse material to see whether any nuggets have been picked up and learn what kind of material is being passed through, so as to enter it in the log-book with the result

of each foot of panning, giving number of colors and size.

As the pump is emptied, the overflow from the pans passes from the pan box into a 6-ft. sluice-box which is made 11 in. wide at the upper end, 8½ in. wide at the lower end, and the sides 6 in. high. This taper allows the small end to enter an inch or so into another such box if more than one is needed. The riffles are made Hungarian style; that is, a 1-in. square stick is beveled to ½ in. on the bottom, with the beveled slope down grade. Riffles are spaced ½ in. apart and held in place by a 1-in. strip on each side, with a ¼-in. mortise for the end of each riffle, which is held securely in place with a 3-penny nail in the end. I make these riffles in two sections so that they can be easily and safely removed without breaking. The panning is done in a tub which is placed within easy reach of the washing-box. When the hole is finished and while the easing is being pulled, the pan box is washed clean into the riffle-box; the riffles are taken out and the material caught is panned to see if any fine colors have been washed over in the sludge. When the easing is up and the core is taken out and panned, then all the tailing is in the tub. The water is then poured off, having ready another tub of clear water; and I rock the tailing as a check on the panner. One tub will easily hold the pannings from a 20 or 25-ft. hole.

PRIMITIVE TRANSPORTATION METHODS, KOREA.

A small rocker is a handy thing with a drill outfit, not only for rocking the tailing, but for other purposes. If, as is sometimes the case, it is necessary to dig a hole in order to start on an examination, the rocker serves to determine whether the gravel on the surface carries gold, as it is quite a task to attempt to pan a cubic yard of such material. The result of each hole is now put into a wide-mouthed bottle, like a small vaseline jar, with a good stopper. On each bottle is pasted a piece of paper on which is written the number of the hole. These are put away until there are enough to spend several hours in retorting (with nitric acid), weighing, computing the gold content, and entering on the record-sheet ready to be copied on the map, which is kept up with the work.

The following is a summary of my work with two Empire drills from November 15 to January 31: No. 1 drill worked 77 days. No. 2 drill, being late in arriving, worked only 50 days. This makes a total of 127 drilling days, covering 203 holes. The total depth drilled was 4112 ft., or an average depth of 20.25 ft. per hole. The average footage per day was 32.37 ft. The total cost for labor outside of my salary was \$357.92, making an average drilling cost of \$0.087 per foot. The rate of wages paid was as follows: boss of No. 1 drill-crew (Korean speaking English and keeping log-book), 50c. per day; coolie operating the spring drilling winch, 25c.; panner (coolie), 22½c. per day. All other coolies got 17½c. per day until they worked with the drill one month, when they were raised to 20c. per day. The only difference in the crew of the No. 2 drill was that the boss is a Japanese who speaks some English and is paid 75c. per day. My interpreter is a Korean with a good English education; he assists with the surveying, retorting, and other work, and receives 75c. per day.

Work of the Ray Consolidated

By D. C. JACKLING

PROPERTY

*The total area of mining land at Ray, Arizona, approximates 1950 acres, and, with the exception of a few unimportant claims, the entire group is patented. In addition to this, the company controls, under long-time lease, certain surface areas adjacent to the settlement of Mexican employees known as Sonora Town. At Hayden, where the mill and smelter are, the area of land owned and controlled amounts to about 4000 acres and constitutes all the surface that is necessary or desirable in that vicinity. Of this area, approximately 3750 acres is owned, the remainder being

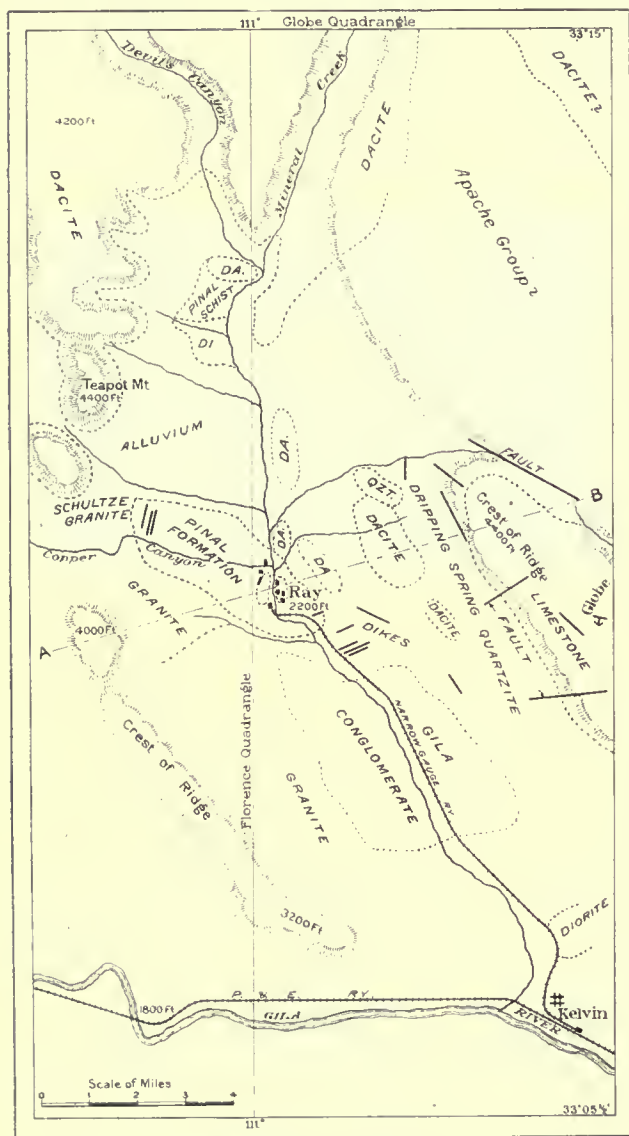

THE MINE

Surface Improvements.—The hoisting plants at both No. 1 and No. 2 shafts are complete. As former reports have shown, these are equipped with skips of 12½ tons capacity operating at a speed of 300 ft. per minute. At the No. 1 shaft, where sufficient tonnage has at times been available, this equipment has demonstrated a hoisting capacity of 600 tons per hour, which is greater than will ever be regularly required. The hoists of both shafts and the shafts themselves are exactly alike, but the No. 2 shaft has for the time being been equipped with only one-half the crushing machinery that has been provided at No. 1.

The main compressor plant, which now consists of two electrically-driven units of a capacity of 300 cu. ft. each, is at the No. 1 shaft. Another compressor of 5000 cu. ft. capacity is now being installed there and all the pipe-lines and connections between this plant and the No. 2 shaft have been completed. This total plant capacity of 11,000 cu. ft. of free air per minute is expected to be ample for the maximum production now contemplated.

The shops, warehouses, etc., to serve the entire mine and the Ray & Gila Valley railroad, are at the No. 1 shaft. The office and officers' quarters and the principal settlement of the company's English-speaking employees are also in this vicinity, although a considerable settlement of American employees has been built up around the No. 2 shaft. The company owns all the buildings occupied by employees near the No. 1 shaft and a few of them in the settlement in the vicinity of the No. 2 shaft. A settlement known as Sonora Town, composed almost wholly of Mexican employees, has been built up on the westerly edge of the company's mining property. This town, which is a little less than two years old, now contains some 4000 inhabitants, and all the buildings, generally speaking, are owned by those occupying them, the ground upon which they are built being leased from the company.

Churn-Drilling.—In my interim report of April 1, 1911. I stated that churn-drilling for development purposes was entirely discontinued in the month of November 1910. Since that time no drilling has been done, excepting where necessary to gain information of value in underground development near the edges of those portions of the ore deposit which are now being worked. Such drilling has resulted in some unimportant changes in tonnages from that stated in my report of April 1, 1911. As the drilling development now stands, the total tonnage calculated is 77,314,470 tons averaging 2.17% copper. Of this quantity, 64,700,000 tons, having an average grade of 2.16% copper, is classed as fully developed, the remainder being classed as partly developed and having an average grade of 2.23% copper. As has been explained in previous reports, the ore classed as fully developed is in deposits that have been drilled regularly and completely in 200-ft. squares, and the partly developed exists in areas that in places have not been drilled at intervals of greater frequency than 400 ft. The total area containing these developments is 183.4 acres. The total number of drill-holes drilled to date is 353, and the total feet of drilling 147,449, the average depth of holes being 417.7 ft. The number of holes showing commercial ore is 277, comprising a total of 121,953 ft. of drilling, and the average depth of these holes is 440 ft. The average thickness of capping, or overburden, is 252 ft., and the average thickness of ore 101 ft. All of the holes containing ore are not considered in the calculations of tonnage, only 238 of them being so used, and representing a total footage of drilling of 106,971. In the area represented by the holes entering into the calculation of ore reserves, the average thickness of ore is 121 ft. Of the total tonnage above stated, about 30,000,000 tons exists in what is known as the East section, or in the vicinity of

MAP OF RAY DISTRICT.

leased from the state. The company also owns a considerable acreage in the vicinity of Kelvin which is used to good advantage in connection with the terminals of the Ray & Gila Valley railway and the junction of it with the Arizona Eastern railroad at that point. The company owns in the vicinity of Ray certain water rights and an interest in the Ray Development Co.'s pipe-line and water-works, which, together, insure a plentiful supply of water for domestic and other purposes. Water rights are also owned and controlled in the vicinity of Hayden, ample to provide the full requirements of water at that point.

*From annual report as general manager for the Ray Con. Copper Co., for period ended December 31, 1911.

the No. 1 shaft, the remainder, about 47,000,000 tons, lying in the West section. Developments by drilling in the East section are practically complete, but in the West section it is known that substantial extensions to the orebody and greatly increased tonnages will result from further development. This is indicated to some extent by the fact that there are 39 drill-holes having ore which have not been used in the calculation of stated ore reserves at all. It is also known that, in many places, existing drill-holes were not driven deep enough to penetrate the orebody, and consequently, that there is ore below the bottom of them. Taking all of the information available, it is not unreasonable to expect that the tonnages stated at present will be increased by 25% or more, when the ore deposits are fully developed.

Underground Development.—The total amount of underground development on January 1, 1912, was 158,898 ft., or a little over 30 miles. This is an increase for the 18

known as the 'shrinkage stope' system, has been applied to sufficiently large areas in two portions of the eastern section to demonstrate its adaptability, both as to economy and safety. In the western section, the extent to which stopes have been developed is not so great, but the ground there has proved equally favorable for the use of this plan of mining, and the work done in both sections has shown the system to be entirely satisfactory.

No mining was done, except in the way of development, until late in March 1911, when the first section of the mill at Hayden was started. During the remainder of the year the mine produced approximately 700,000 tons of ore. The amount is stated approximately, as no account is taken of ore broken in stopes, in storage at the mine-bins, or in transit to the mills, the basis upon which the mine is credited with production being the weights at Hayden. The total amount of ore with which the mine was given credit at the mill was 681,000 tons containing 1.83%

CENTRAL PORTION OF RAY DISTRICT.

months of 122,000 ft., or at the rate of nearly 7000 ft. per month, and approximately this rate is being maintained at the present time. The areas adjacent to both shafts have been, and are now being, developed on two principal levels, although in both cases auxiliary levels are being worked above the No. 1 or main upper levels. The No. 2 levels in both cases are at such elevations that they will eventually be joined and form one connected working covering the entire property.

All of the ore mined up to date, excepting small quantities coming out of development work, has come from above the No. 1 level. It will not be long, however, until some mining can be done tributary to the No. 2 level at either shaft, and no extensions of these shafts have been made below that level, excepting such as are necessary to accommodate pumping stations to take care of the small amount of water produced.

The grade of the orebodies, as determined by churn-drilling, has been checked satisfactorily by the underground development as it progressed. The copper content of all the ores mined has varied only slightly from what was expected from calculations of drill-hole results in the areas and zones from which these ores came. The underground work, both as to development and mining, has up to date satisfactorily checked the drill-hole averages.

The system of mining employed, which is commonly

copper. Of this quantity, about 150,000 tons, or something over 20%, came from storage ore previously produced in development, so that only about 530,000 tons of ore was actually mined from underground during the period, and of this amount about 350,000 tons came from stopes and the balance from development.

The actual cost for the period, including coarse crushing of the ore, as well as all general and fixed charges, was \$1.6c. per ton. This cost includes many extraordinary expenses incident to starting up and a higher ratio of fixed charges than would apply on a greater tonnage, and is correspondingly higher than it will be when additional areas are opened and a larger tonnage can be conveniently produced. In fact, the cost for the last quarter of the year, as stated in a previous report, was 76c. per ton, and it is not expected that the cost of mining for the current year will exceed the estimate of 75c. per ton made in my quarterly report dated October 25, 1911. This figure is believed to be sufficient to cover not only current operating costs, but also a charge sufficient to retire all the investment we have expended, or will expend, in the underground development of the property. At the time of writing this report, the mine is producing from underground approximately 3600 tons per day, and it is expected that the output will be increased to 5000 tons per day by or shortly after the middle of the current year.

The grade of the ore is still lower than normal, somewhat lower, in fact, than the average applying up to the end of 1911, and this condition will continue to some extent until we have mined out the orebodies near the surface on which we are now working in the west portion of the area tributary to the No. 1 shaft. Our largest increase in tonnage in the immediate future will come from areas tributary to the No. 2 shaft, where the grade is better and some improvement in average value will follow, but we do not expect to maintain a normal grade at the average of the mine until we can derive some tonnage from the No. 2 level of the eastern section, and no considerable amount can be so derived until the upper zone in that section has been further removed. As has been stated, the grade of the ores we are producing checks with the grade indicated both by drill-hole and underground development in the areas from which it is coming.

THE HAYDEN PLANT

Construction.—The mill is constructed in eight sections having a normal capacity of 1000 tons per day each, as described in previous reports, and no changes in design of material consequence have been made. The first section of the mill was completed and put in operation in March 1911. Subsequent to that time, additional sections were completed until, at the end of the year, five sections had been finished, and four of them have been practically in continuous operation since completion. The three uncompleted sections are so well advanced that they can be finished at about the rate of one section each thirty days as required, all the necessary machinery for their completion being on the ground.

The power plant is complete, although its full capacity will not be required until the entire mill is in operation. The transmission line from this plant to Ray is in continuous and satisfactory commission furnishing all the power used at the mines. The pumping station for main water supply, machine shops, warehouse, and all accessories to the plant are completed and in satisfactory operation. Office buildings and quarters for officers and employees have also been provided adequate for present needs, and it will not be necessary to add extensively to these for the future. The company owns all the buildings adjacent to the plant excepting those occupied by Mexican employees to the west. The A. S. & R. Co. is rapidly completing its smelter, and it is expected that smelting operations will begin about May 1.

Operation of the Mill.—The first section of the mill was started about the middle of March 1911, but did not operate continuously until after April 1. Another section was started in April, and since that time three additional sections have been completed, as previously stated, although it has not been necessary to operate more than four of them at any one time to accommodate all the tonnage available. It was found desirable immediately after beginning operations to modify somewhat the arrangement of machinery and distribution of products in order to get satisfactory results. These alterations required the installation of only a limited amount of additional machinery, principally classifiers, and were not expensive in point of direct cost, but they required some time and correspondingly delayed the accomplishment of high recoveries, so that the company did not commence to secure the results that had been anticipated until during the last quarter of the year. During that period the extraction percentages increased regularly and rapidly, and at the end of it were all we had expected. The work of the plant is now entirely satisfactory in every respect, the recoveries being 70% on a grade of ore which is nearly $\frac{1}{2}\%$ lower than the average for the property. All of the five sections now ready for operation have been rearranged, and, so far as now known, no further modifications are necessary to insure regularly the extractions now prevailing and substantially higher percentages as the grade of the ore improves.

The total ore treated for the year was 681,519 tons of an average grade of 1.83%, resulting in a gross output of copper contained in concentrates of 15,721,520 lb., and cor-

responding to an average extraction for the entire period of 63.1%. For the last quarter of the year the extraction was 66.27% on an ore assaying 1.73% copper, and for the month of December the extraction was 67.38% on an ore containing 1.66% copper, resulting in as great a recovery in terms of pounds per ton of ore on this lower grade ore as was experienced for the entire period on a considerably higher grade of material, and indicating clearly improved conditions. During the month of February just closed, the recovery was 70.32% on an ore averaging 1.68% copper, and at times during that month the rate of treatment per section averaged over 1100 tons per day, or at the rate of about 9000 tons for the completed plant of eight sections. There is no question but that equally good results will be regularly maintained hereafter.

The net cost of producing copper for the year, after crediting dividends from the Ray & Gila Valley railroad, was $10\frac{3}{4}c.$ per pound. This cost was incurred, however, in connection with shipping all of the concentrate produced to El Paso at a freight and smelting expense of approximately $1\frac{1}{2}c.$ per pound greater than is now resulting through the delivery of concentrate to the A. S. & R. Co.'s new plant at Hayden under contract with that company. Had the management been able during the period under discussion to have delivered concentrate to Hayden, under the contract which is now in effect, the average cost per pound for the year would have been 9.33c., and on the same average grade of ore the actual cost at the present time is about 9c. per pound. The average assay of concentrate produced for the period was 22.4%, this feature as well as others of concentrate analysis being almost exactly what had been expected as a result of early experiments. As it becomes possible to increase tonnage, all factors of operating costs will decrease correspondingly. This will apply especially to the cost of power, as it will not be necessary to employ any additional operating force to supply power for the entire mill. Fixed and general charges will also be decreased by distributing them over a greater tonnage, and, as stated in the discussion of mining conditions, the cost of mining will in the future be lower. Taking all these factors into consideration, there appears no question whatever, about the ability of the property to produce copper at 8c. per pound, when running at full tonnage and on a normal grade of ore. As a matter of fact, if the mill were now running on a 2% ore and making no greater percentage of recovery than at present, and experiencing the same costs per ton that now apply to operation at less than one-half the mill capacity, the cost per pound would be less than $8\frac{1}{4}c.$ Summing up the whole situation, every factor pertaining to the Hayden plant and its operation, including those of water supply and the transportation and delivery of ores, is entirely satisfactory.

RAY & GILA VALLEY RAILROAD

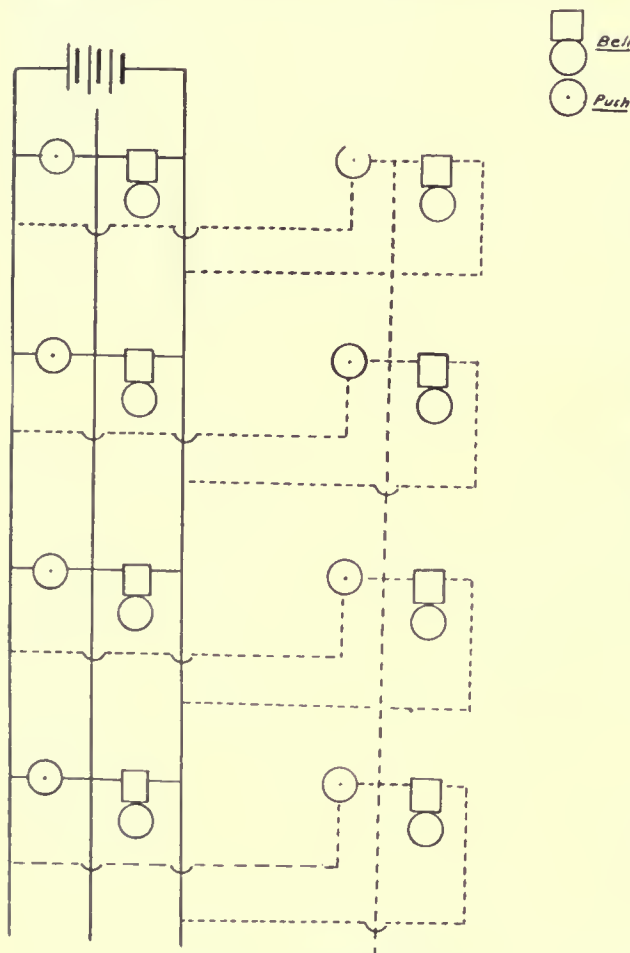

The Ray & Gila Valley railroad, which is owned by the company, connects the town of Ray with Kelvin and Ray Junction, the latter being the point at which it joins the Arizona Eastern, a branch of the Southern Pacific railroad. During the year the line was extended to the No. 2 shaft and a permanent station established near that point for the convenience of the town of Ray. Another branch extends from a point on the Arizona Eastern line to the mill at Hayden, a distance of about three miles. The total trackage, including sidings, is about sixteen miles, the total length of the main line in the two branches being about ten miles. The distance via the Ray & Gila Valley and Arizona Eastern between Ray and Hayden is about twenty miles.

The present equipment of the line consists of three locomotives, one hundred and twenty 60-ton steel ore cars, and the small amount of equipment necessary for passenger and commercial freight business. Up to the present time the management has been able to handle the entire main line business with one locomotive, although an additional locomotive is at times used for switching or emergency service, leaving a third locomotive constantly in reserve. The road and its equipment is in excellent physical condition and its operation is resulting in substantial profits.

Bell Signaling and Cable Systems in Shafts at the Crown Mines, Limited

The following detailed account of the signaling system was prepared by Mr. Curtiss, electrical engineer for the Crown Mines, Ltd., and is published through the courtesy of W. W. Mein.

Signaling System.—This allows the interchange of signals between any station and the engine-driver, such signals sounding at all stations. In its simplest form it consists of a battery preferably of accumulators, a bell and pull at each station and at surface, and three wires connecting all stations with the surface. Our battery wire is connected to a terminal of every bell, the other to a terminal of every pull, and the third wire forms a common

CROWN MINES SIGNAL SYSTEM.

connection between the other terminals of both bells and pulls. The arrangement is shown in the attached sketch. The two battery wires may, and in practice generally do, feed a number of systems, though, of course, there must be a separate 'common' wire for each system. The dotted lines in the sketch show a second system fed in this way.

Bell Cable.—Where any trouble from moisture is likely to be experienced, bell cable is used. This consists of a number of rubber-insulated wires incased in a lead covering which in turn is covered with jute and armored with steel wires. There is a final covering of jute over all to prevent corrosion. The standard cables are 4-core and 7-core, but special cables may be made up as desired. The copper in each core generally consists of seven No. 20 S.W.G. wires, equivalent to about 9000 circular mils.

Junction Boxes.—At each station where bells are desired the main cable is taken in and out of a 'T' junction box. A branch cable from this box is run to the bells and pulls in the station. In the junction box is a marble terminal board with binding post passing through it.

Each of the wires of the incoming and outgoing and branch cables is connected to the bottom of a binding post, and the box is then filled with paraffin wax or compound, level with the top of terminal board, thus sealing all cable ends. The connections between the upper parts of the binding post are made with copper straps which may be easily removed when testing for faults. The box is provided with a lid which when bolted down makes the box quite water-tight. It is not customary to use these boxes in situations where trouble from moisture need not be feared.

Bells.—Any water-tight bell may be used, but probably the most satisfactory type is that manufactured by Siemens, Limited. This has the mechanism enclosed in a water-tight metal box, on the side of which is soldered a metal diaphragm. The armature is attached to the inside of the diaphragm and the bell-bammer to the outside of the same. This allows the parts damageable by moisture to be hermetically sealed.

Pulls.—There are many satisfactory forms of pulls and push-buttons. If used in very wet places, it is well to fill the pulls with vaseline.

Distance Between Junction Boxes.—If no tappings are required, there is nothing to limit the length of bell cable between boxes except for the convenience in replacing a damaged portion. In the case of the South Rand shaft, where no bells are required between the surface and a depth of 2000 ft., pockets are cut in the rock to provide dry places for junction boxes at depths of about 800 and 1000 ft., so that in case of a failure it will probably not be necessary to replace a greater length than 800 feet.

Power Cables in Shafts.—The power cables at the Crown Mines are 2200-volt, 3-phase, 3-core, paper insulated, lead covered, steel-wire armored, and jute-covered cables. The cross-section of each copper core is from 0.1 to 0.2 square inch, depending on the load to be taken care of. Where the larger size is not sufficient to carry the load, additional cables are installed, as it is not economical to increase the size of such a cable much above 0.2 sq. in. These cables are specially made for shaft work and do not contain any free oil, otherwise the lead might be ruptured by the static pressure of the oil. Here again the length between the boxes is determined largely by the idea of replacement in case of failure. The longest length on Crown Mines is about 1000 feet.

Installation.—Neither the bell nor power cables referred to above are able to carry their own weight for any great length. They are lashed or clamped about every 70 ft. to a wire rope when being lowered into place. The lashings or clamps are gradually removed as the cables are cleated to the shaft timbers.

In the northern part of Minnesota there is a great area of land so flat that its waters sometimes flow into Hudson bay and sometimes into the Gulf of Mexico. This area contains the headwaters of the Mississippi river. There are times when certain lakes discharge at both ends, the northern outlet taking the flow through Red river or Rainy river into Lake Winnipeg, and thence into Hudson bay; while the southern outlet leads to the Mississippi. Therefore the dividing line between the Mississippi drainage basin and that of Hudson bay is indefinite and in many places cannot be determined, and the consideration of these two basins in connection with their water supplies and the uses that can be made thereof must logically be taken up together.

PLACER deposits of great richness have been found on the Chukot peninsula, Kamchatka, according to a recent report by a Russian engineer. In the northern part of Kamchatka, on the Anadyr river, rich placers also occur. The Anadyr Mining Co. (Russian) has sent an expedition to this area and a number of Danish engineers have also started in behalf of Danish capitalists. The Russian ministry has approved of a scheme for allotting the land to private individuals and will first investigate its value.

The Los Burros Mining District

By CHARLES H. DAVIS

The Los Burros mining district is in the extreme southern part of Monterey county, California, mostly in township 23 S.; range 5 E.; and township 24 S.; range 5 E., Mt. Diablo meridian. The largest mine in operation, the Buclimo, and the old townsite of Los Burros are on a north gulch of Alder creek, township 24 S.; range 5 E.; section 2. The two important placer workings are on Willow and Dogvine creeks in township 23 S.; range 5 E. Plaskett's find of May 1911 is near the latter creek. The official map of Monterey county, compiled in 1898 by Lou G. Hare, county surveyor, has been used as a basis for work.

The principal deep mine, the Buclimo, J. C. White superintendent, is owned by Messrs. Burnham, Clinton, and Mory, of San Francisco. The Plaskett property is owned by old residents of that name. They have both placer and deep mining claims. The Gorda Gold Mining Co. works the placer deposits on Willow creek during the rainy season and early summer.

GEOLOGIC RELATIONS

Igneous Rocks.—Serpentine, probably altered from a gabbro, occupies a considerable area in the district. Thin sections of the rock show no olivine remaining, but do show bastite, a pseudomorph of an orthorhombic-pyroxene, the presence of which is indicative of the igneous origin of the serpentine. The rock in hand specimen is fine and even in texture, and almost glassy in appearance at times, especially where it is sheared. In color the rock is dark green, not mottled but of even color. Along the Jolon trail the serpentine is bluish green and purple.

The serpentine occurs in the form of dikes extending irregularly along the coast from the ocean at Gorda southeasterly through San Luis Obispo county. These dikes occur, to my knowledge, as far north as Gamboa's, on Big creek, and eastward they are exposed nearly to the Nacimiento river, where in the first ridge the Miocene sandstone lies upon them unconformably, so far as could be determined. This would make the age of the intrusions pre-Miocene and probably pre-Tertiary, yet the exact age can only be determined by fixing that of the older sandstones and shales intruded.

Sedimentary and Metamorphic Rocks.—The country rock in the mining district varies from a distinct sandstone of fine even grain, to a shale which is so metamorphosed near the mineral veins that it is properly termed slate. Conglomerate beds are rarely found, and are so fine in texture that they are hardly worthy of the name. In thin section the slates from the Buclimo exhibit the characters of a microscopically-fine arkose—if such an expression may be used. The small grains of quartz, feldspar, and chalcedony are sub-angular, a fact which, added to the presence of the feldspars, shows that the rock materials were transported only short distances. Carbonaceous material (graphite in the metamorphosed areas) gives the rock its deep gray or black color. The slates are infiltrated with fine quartz and calcite veins, especially in the immediate mining district. Several beds of white quartzite occur near the Buclimo and also about a quarter of a mile to the east. These beds appear to be sedimentary in origin.

Just south of the Buclimo workings is a small area of rock which has the character of a greenstone. It contains principally the quartz, feldspar, chalcedony, calcite, and chlorite. In appearance the outcropping rock is a dark olive-green, weathering brownish green; it has been irregularly fractured to quite an extent, and the fractures filled with calcite. Its metamorphic character and its position near the slates suggest local metamorphism in the mining district. The extent of the metamorphosed area has not been worked out. The age of the sandstones and slates is probably Franciscan (Jurassic). Jurassic fossils have been found in the slates at Slate Springs, to the north, where the

formation is the same as in the Los Burros district.

Structure.—The structure, upon reconnaissance, seems to be monoclinical; dip generally steeply to the east; strike 40 to 45° west of north; texture of beds uniform; bedding not prominent; structure regular. The structure agrees with the direction of the valleys of the Nacimiento and Burro creeks to the east of the territory and with the trend of the coast line. The weathering is slight and is limited mostly to staining and discoloration.

ORE DEPOSITS

Outcrop.—The outcroppings of the gold-bearing veins yield placers which are richest in the canyons and gulches leading to the Pacific. Deposits also exist in the gravels of the San Antonio and Nacimiento valleys to the east. The latter deposits are of little economic value, although they were worked for several years by Chinese. The mineral veins fill fissures which are nearly identical with the bedding of the country rock. These veins run through slates, sandstones, and serpentines alike, but the ore seems to vary in richness with each of these formations. The following are some of the minerals found in the vein and wall-rock: free gold, sulphides carrying gold, chromite, pyrite, and mariposite, the last being a rare mineral found mostly in the Mother Lode district.

CONDITIONS AFFECTING MINING

• *Topography.*—The Los Burros mining district is just west of the crest of the Santa Lucia range, with summits at this point about 3500 ft. above sea-level. The top of the Buclimo shaft is 2800 ft. above sea-level, and this elevation represents the general level of the outcrops of the vein. The mines and prospects, therefore, are at the heads of the deep gulches which open into Alder, Spruce, Willow, and other creeks flowing into the Pacific. The Pacific slope of the Santa Lucia range is steep, having a descent of 3000 ft. or more in three miles. The creeks have attained an even, though steep, gradient from their heads to the ocean, in most cases. The ocean is bordered by bluffs which rise steeply from the beach at an angle of nearly 30° to an elevation of about 1800 ft. To the north of this district, the trail leading to Gamboa's sometimes skirts the foot of the bluffs and is passable only at low tide. To reach the district from the railroad, one must travel from King City, on the Southern Pacific railroad, to Jolon, a distance of nineteen miles, by stage, and then twenty-one miles by trail to the mines. Of this twenty-one miles, the first ten, as far as the Nacimiento river, may be traveled by wagon. The remainder of the trail is narrow and steep, so that all provisions and supplies for the mines must be carried on pack animals. Trails approach the district from both the north and south along the coast, but the one from Jolon is the best and most used for provisions, mail, ore, and by prospectors.

The transportation facilities, aside from those of the Jolon trail, are meagre. At intervals, usually once a year, a boat is chartered to bring provisions, lumber, machinery, and various supplies to the landing near the mouth of Willow creek. The few inhabitants along the coast share in the cost of the enterprise, and send back in the boat the products of the region, which consist of redwood timber, lime, cattle, and hides. There is often considerable difficulty in landing supplies on account of the heavy surf and the lack of protection from the open sea. The old Los Burros townsite was plotted upon a fairly level piece of ground sloping into a gulch opening into Alder creek. This area is just below the old Last Chance mine (now the Buclimo) and is at an elevation of 2500 ft. above the sea. Two or three acres of this land are tillable, but the rest is, sloping and brushy. The customary building sites, and the best of the region, are those at an elevation of about 1800 ft., at the crest of the bluffs overlooking the sea. Here

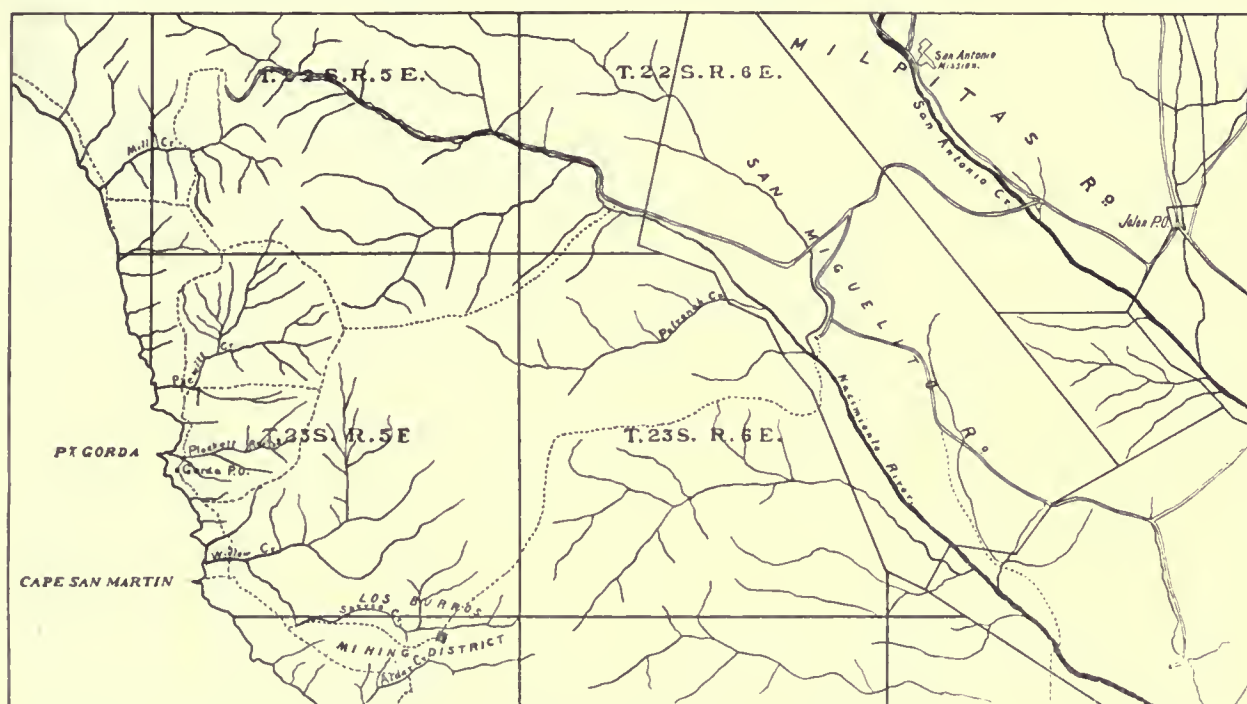

is often found a strip of open grazing or farming land. The sides of the sea bluffs are too steep for building purposes. Waste and tailing is dumped into the steep-sided gulches.

There is no timber on any of the most promising properties. Redwood trees are abundant on the sides of the coast canyons to an elevation of about 250 ft.; oaks, including some tan-bark oaks, grow at the lower elevations; and sugar pines and the Santa Lucia fir are scattered among the redwoods at the higher altitudes. Some of the timber land is homesteaded, but much of it is in the Monterey National Forest and is cut under the supervision of the forester and sold to the mines. The only fuel supply at hand is that derived from the timber described above—oak, pine, fir, and redwood.

Water cannot be stored with any facility above the main workings. The chief supply is from springs and, in the case of the Buelimo, from the pumpings of the mines and from a spring connected with the mill by 1800 ft. of pipeline. Work in this mine has been prevented by an excess

Buelimo Mine.—The Buelimo mine is situated near the head of a steep-sided gulch opening into a north branch of Alder creek. The main entrance to the mine is through an adit 750 ft. long opening upon the first level. The first level is 97 ft. below the surface and has a 600-ft. ore-shoot. The second level, 197 ft. below the surface, has now a 600-ft. ore-shoot developed. The shaft, which is $4\frac{1}{2}$ by 9 ft., extends to a depth of 247 ft., having one compartment to the first level and two compartments to the second level. It is equipped with a bucket, a steam-hoist, and a steam-pump. A raise connects the stopes of the two levels. The raise and levels are timbered, but the adit is cut through hard slate and greenstone, both of which stand firm without timbering.

The ore is taken out on a tramway through the adit and then about a hundred yards farther, where it is dumped into the ore-bin above the mill. The ore is treated in a 5-ft. Huntington mill which has a capacity of 12 tons in 24 hours. Simply the free gold is obtained from the ore; the tailing, which contains quite a percentage of sulphides, was until 1911 disregarded, but is now being saved for further treat-

MAP OF LOS BURROS MINING DISTRICT, CALIFORNIA.

of water in winter and at times by drought in summer. Work in the new Plaskett mine, however, has been delayed on account of lack of water, since the mill was built upon the hillside. The placer deposits are worked on a large scale only after the rainy season has started in January, and from then till summer. Power is not directly available at the mines except from wood fuel, but electrical power could be developed on Willow, Prewitt, and Mill creeks. Fifteen miles to the north is Big creek, a stream which could probably furnish over a thousand horse-power throughout the year.

Extremes of climate are not suffered, although the ground freezes slightly at times in December and January. In summer the thermometer rises to 100°F. or more, but the elevation aids in making living quite comfortable. The rainfall is very heavy; for a period of over ten years the average year rainfall was between fifty and sixty inches at a station, in the heart of the district, kept by James Krenkel. The rain falls mostly in January and February.

DEVELOPMENT

The entire mining district, which is about three by nine miles, is staked out in claims upon which assessment work has been or is being done. The only mill (until the fall of 1911) was upon the Buelimo property. Therefore, since that mine is the only one extensively developed, a report upon it will be given.

Plans to cut the vein at about the 400-ft. level by means of a new adit are being considered by the owners of the Buelimo.

History of Discovery and Development.—The history of the discovery and early development of the Los Burros mining district was published by the California State Mining Bureau in the Eighth Annual Report of the State Mineralogist for the year ended October 1, 1888. Briefly, a part of this report follows.

"In 1887, W. D. Cruikshank was prospecting in Alder creek and discovered a 'blind lead' from two to four inches wide, containing free gold. He commenced sinking upon it, and the vein widened as he went down. He then crushed about 20 lb. in a hand mortar, and washed out \$18 worth of gold. He continued sinking and put up a horse arastra. This he used for about four months, during which time he realized enough to erect a 3-stamp mill and a 2-hp. engine. He operated from November 1887 to the first of June 1888, when a failure in the water-supply, caused by draining the upper workings of the mine, compelled the removal of the mill, and a consequent temporary suspension of milling operations. Further development of Mr. Cruikshank's mine, which is called the Last Chance, has brought to light five distinct leads, each showing well defined quartz veins, three of which have been found of sufficient importance to work."

Since 1888, no report has been published about the district either by the State of California or by the U. S. Geo-

logical Survey. After working the property for two years, Mr. Cruikshank sold the Last Chance to T. A. Bell, who carried on mining for two years. Messrs. Cruikshank and J. M. Krenkel, district recorder, then leased the property for nine years. The mine then lay idle until 1908, when the Bank of California, which had the settling of Mr. Bell's accounts, sold the mine to a San Francisco company. The names of the new stockholders give the mine its new name, Buelimo. At the present time the mine is employing about twenty-five men in summer and about six in winter.

In 1902, important placer discoveries were made on Willow and Dog-vine creeks, and to work them, two mining companies were formed, the Gorda Gold Mining Co. and that of the Plaskett brothers. Many large nuggets were found in these deposits, the largest being one worth \$800 on the Gorda claim, and one worth \$104 on the Plaskett claim. Since the opening of the district placer work has been carried on by individuals, on a small scale, in all the nearby creeks and gulches. On February 7, 1911, the Bushness find was made, and toward the last of May 1911, the Plaskett find excited wide attention on account of the richness of the outcropping ore. It is upon the latter property that a 3½-ft. Huntington mill has been installed. About the first of February 1912 another discovery was made at Plaskett's. The outcropping vein is one to eight feet wide, and, according to information received from Mr. Krenkel, it is as rich as the find of 1911.

Production.—The production of the Los Burros mining district, so far as can be learned, is given below. No estimate can be obtained of the value of the placer production before the year 1904, but Mr. Krenkel estimates the output of the deep mining for the period 1888-1904 at \$120,000. The remainder of the data is from the 'Mineral Resources of the United States, 1905-1909.'

Year.	Placer.	Deep gold mines.	Total.
1888-1904	(est.) \$120,000	?
1904	?	?	\$6,295
1905	\$1,248	125	1,373
1906	300	325	625
1907	250	826	1,076
1908	500	818	1,318
1909	0	333	333

Coal Production of New Mexico

The production of coal in New Mexico in 1911 was 3,148,158 short tons, with a spot value of \$4,525,925, according to a statement by E. W. Parker recently made public by the U. S. Geological Survey. In common with most of the states in the Rocky Mountain region, New Mexico produced less coal in 1911 than in 1910. Several causes contributed to the decreased production—unusually mild weather in the winter of 1910-11, a drought in the Great Plains states which reduced the demands for coal for domestic use, decreased consumption by railroad locomotives, and the resumption of coal mining in the Central and Southwestern states after the six months' strike of 1910. The combined effect of these influences on the coal production of New Mexico was a decrease of 360,163 short tons, or 10.3%. The value declined \$351,226, or 7.2%. All the counties of the state showed decreases in production except McKinley county, which increased 32,635 short tons. Colfax county, in addition to producing 75% of the total output of New Mexico, is also the only county in which coking operations are carried on, and in 1911 a total of 767,108 tons of coal mined in that county was made into coke. In 1910 the coal made into coke in Colfax county amounted to 701,204 tons.

JAPANESE living at Chinnampo, in Korea, propose to erect a blast-furnace there to smelt the iron ores which are now being shipped to Japan. The mines, which occur in north and south Phyonan and Huanghai provinces, have produced about 12,000 tons annually, but it is expected that 150,000 tons will be produced in 1912.

The Nature of Sherardizing

By J. W. RICHARDS

*Sherardizing is an intensely interesting process, based on clear-cut but not very generally understood scientific principles. As proved in the paper, coating with zinc takes place regularly below the melting point of zinc, with probably no distinct break at the melting point, as long as the zinc-dust does not run together to fluid zinc. The process is without doubt operated by the vapor tension of the zinc, on the one hand, and the ability of the other metal, iron, copper, nickel, or brass, to absorb zinc vapor, on the other hand. The process depends on 'a push and a pull,' the tendency of the zinc to vaporize and the tendency of the other metal to absorb the vapor. In the absence of numerical values for the heat of combustion of zinc vapor with iron, copper, nickel, or brass, to form alloys—the pull—I have reproduced a diagram showing the probable vapor tension of zinc at low temperatures, derived by analogy from the vapor tension of mercury at low temperatures, as printed in my 'Metallurgical Calculations, Part III.' While the figures given are not experimental results, yet they are worthy of consideration as first approximations. Johnson and Woolrich's results, as given in their Plate II, show that at a given temperature different metals absorb zinc vapor with different velocities; also that a given metal, at different temperatures, absorbs zinc vapor with different velocities. The first information tells us that sherardizing depends partly on the specific attraction of the metal being plated for zinc vapor, the second makes it a probable assumption that it also depends upon the specific ability of the zinc-dust to produce zinc vapor at the different temperatures.

As to the latter point, the vapor-tension curve of zinc gives us interesting conclusions. Johnson and Woolrich made 30-minute tests with copper, nickel, and iron, at 325°, 375°, and 425°C. They give the weights of zinc absorbed at these temperatures, and we can compare these with the vapor tensions of zinc at the same temperatures:

Temperature, °C.	Tension of zinc vapor, mm. Hg.	Relative tensions.	Square roots of relative tensions.	Relative Deposits.		
				Copper	Nickel	Iron
325	0.002	1	1	1	1	1
375	0.028	14	3.7	2.4	3	4
425	0.183	92	9.5	4.8	6.3	10.9

The fourth column is added because it would appear *a priori* that if the tension of zinc vapor was zero at the absorbing surface, the driving force causing diffusion of zinc vapor would be the maximum possible tension at the vaporizing surface, and the quantity of zinc diffusing, being proportional to the diffusion velocity, would then be proportional to the square roots of those maximum tensions. It appears that the agreement is not bad; in fact, in the case of iron, it is quite instructive.

After the immediate surface of the metal becomes coated, the absorbing power must rapidly decrease, and the rate of absorption would then be limited by the rate at which the zinc soaks in, or is transmitted inward, from the surface. It appears from Johnson and Woolrich's results, that while copper and nickel have a greater combining power than iron, as far as their immediate surfaces are concerned, they do not, however, maintain that rate when greater quantities of zinc are absorbed at a higher temperature: the iron is evidently relatively more permeable to further absorption of zinc, at the higher temperatures.

*Discussion of a paper by A. R. Johnson and W. R. Woolrich, presented at the Boston meeting of the Amer. Electrochem. Soc., and printed in the *Mining and Scientific Press*, April 20.

Iron and Steel Division of the A. I. M. E.

The Council of the American Institute of Mining Engineers, at its meeting on April 26, established an Iron and Steel division to represent the interests of the Institute in the mining and metallurgy of Iron and Steel; its business to be in charge of the following committee, upon which shall rest the responsibility for securing papers and discussions on Iron and Steel for the meetings of the Institute: Charles Kirehloff, chairman; Charles F. Rand, vice-chairman; Bradley Stoughton, secretary (165 Broadway, New York City); John Birkinbine, James Gayley, Henry D. Hibbard, Henry M. Howe, Robert W. Hunt, Julian Kennedy, Charles K. Leith, Richard Moldenke, Joseph W. Richards, F. W. C. Schmiewind, Leonard Waldo, William R. Webster, Felix A. Vogel.

This committee has met and formulated plans for carrying out its intention of securing papers and discussions dealing with all phases of the mining and metallurgy of the ferrous metals, to such an extent as will make the American Institute of Mining Engineers the foremost iron and steel association in America, useful alike to the theoretical as well as the practical iron and steel man. The following subjects have been suggested: geology, mining, and preparation of ores; concentration; nodulizing, sintering, and briquetting; manufacture of coke and other fuels; refractory materials; blast-furnace, bessemer, open-hearth, and electric furnace practice; the duplex process; treatment, physics, and chemistry of iron and steel, including metallography. A campaign has already been started to secure papers and discussions on: alloy steels, heat treatment of steel, the duplex process, the thin-lined blast-fur-

nace, fuel gas for open-hearth furnaces, ore concentration, manufacture of pig iron, mechanical charging of blast-furnaces, gas producers, charcoal iron, electric furnaces, recent improvements in open-hearth furnaces and practice. The committee will use its utmost endeavors to bring the papers presented on iron and steel to the attention of all members who are qualified to discuss them, and to stimulate a continuance of the discussion until all available data and information of interest have been secured for the *Transactions*.

A GEOLOGICAL examination should not confine itself to the points then needed. All features of an ore deposit are the result of geologic processes, and it is impossible to foretell just which ones are likely to be of economic importance in any one case. A man in charge of exploratory work should make an effort to work out the geologic history of the region, feeling sure that even an apparently theoretical matter may eventually prove to be of practical importance. This, of course, does not mean that a detailed geological survey should be made before an adit is driven or a shaft is sunk; it means that the man in charge of the work should be trained in field geology and should be capable of interpreting the geologic features that come to his attention day by day. In many cases questions will arise that can be settled only by an expert. It is therefore of importance that the man in charge of the work be familiar enough with the significance of geology to know when to employ specialists.

DREDGE TAILING is causing difficulty in the Wagga, New South Wales, district, and at a recent meeting of the citizens of Wagga it was proposed that no dredging shall be allowed on the watershed of the Murrumbidgee river.

Mineral Production of Colorado by Counties

Gold, \$20.67; silver, \$33.03; lead, .04465; copper, .12219.

El Boleo Smelting Practice

By AN OCCASIONAL CORRESPONDENT

The chief interest attaching to the copper-smelting methods at the plant of the Compagnie du Boleo at Santa Rosalia, Baja California, results from the remarkably high percentages of silica and alumina in the charge. It is doubtful whether any other smelter in the world has continuously for long periods produced a slag averaging approximately:

	Per cent.
Silica (SiO_2)	52
Alumina (Al_2O_3)	18
Ferrous oxide (FeO)	6-8
Manganese dioxide (MnO_2)	4-6
Calcium oxide (CaO)	10-12

This unusual practice is due to the commercial necessity of dispensing with costly fluxes. Although deposits of hematite, pyrrhotite, and to some extent of pyrite, are not uncommon in Baja California and along the west coast of Mexico, they are generally unavailable for use at port smelters, owing to their inaccessibility, and also because of the low tenor in marketable metals characteristic of the west Mexican ores. High-grade ores in that region have never yet been developed in commercially important quantities. Hence the fluxes which are known to exist would more than eat up the value of the marketable metals in the smelting ores. At El Boleo, for example, the average copper content in the charge lies roundabout $4\frac{1}{2}\%$. It will readily be seen that the best California fluxes, even if sold at prices barely covering the cost of mining and loading, could not stand the charges of transportation by land and sea, plus the cost of putting through the furnace, with an ore of such grade, and the west Mexican fluxes would cost even more to move to Santa Rosalia than the ferrous ores of California.

While full details of El Boleo practice, rendering possible so brilliant an achievement as that attained by M. Michot, the manager, in reducing the FeO requirements to 6%, are not at hand, the conditions are sufficiently well known to give to a metallurgist an appreciation of the leading features.

The furnaces are of the most simple construction, measuring 12 ft. 6 in. by 3 ft. 6 in. inside, at tuyere-level. The water-jackets are 2 metres high, succeeded by 2 metres of brick shaft extending up to the charging-floor. The feed-doors are about 4 ft. high, the iron hood contracting above these to the chimney, from which latter the down-take leads off to the dust-chambers and main chimney. The furnaces are built with crucibles, and the settled matte is tapped off at intervals. It was found economically impossible to employ a forehearth on account of the rapid chilling of so acid a slag. A curious feature of the slag-discharge is that it is allowed to flow continuously from each end of the furnace through 4-in. slag-ports. It would occur to a metallurgist at once that this would lead to enrichment of the slag in copper. Actually the Boleo slags carry not less than 0.5% Cu, which is above what the majority of smelter managers elsewhere are willing to concede. The separation of the matte under such circumstances must be extremely rapid, else the slag would certainly carry much more than 0.5% Cu when drained from the slag-line inside the furnace. This may be explained by the high degree of fluidity imparted by the considerable quantity of manganese, at the high temperature prevailing just below the fusion-zone inside the furnace, but beyond doubt the high specific gravity of the matte contributes to this result, its copper tenor being above 60%, and often more than 65%. In passing, it is of interest to note that a premium of £2 per long ton is paid by the European refiners for matte of this grade, owing to its desirability for mixing with low-grade mattes for blowing in the converter.

It will be noticed that the furnace is relatively narrow (42 inches), that the column is relatively high (13 ft., $11\frac{1}{2}$

in.) and relatively long (12 ft. 6 in.). The tuyeres are 12 in number on each side, and have a diameter of 4 in. Thus conditions are favorable for a good air-penetration at moderate pressure, the water-gauge actually reading between 50 and 60 centimetres.

The furnaces are run very slowly, each of the ten in blast smelting about 250 tons of charge per day. They are operated with a cool top, which is partly due to the slow speed of smelting and partly to the fact that the charge carries from 20 to 30% of moisture, the evaporation of which lowers the temperature in the upper part of the stack. Only a small proportion of the moisture contained is present as combined water. The copper in the ore is almost wholly in the form of chalcocite and covellite. The coke used amounts to about 12% of the charge, and it is claimed that it is more perfectly burned to carbon dioxide than is usual in copper-smelting practice in America.

Removing Fusions From Crucibles

By J. C. BOCK

In making fusions for the determination of silicates it is often hard to remove the fused mass from the platinum crucible, especially when the crucible is somewhat old. I remove the fused mass in the following way: A piece of nickel plate about 1 mm. thick and 5 to 8 cm. square is bent upward around the edges. This plate is placed on a layer of wet cotton or filter paper. Care must be taken to keep the upper surface of the plate perfectly dry.

When the fusion in the crucible is complete, raise the temperature as high as possible, taking care that the crucible is white hot on the side from which the fused mass is poured. Pour the melt quickly upon the plate. After a little experience it will be possible to remove the largest amount from the crucible in this way. The fused mass on the plate forms a flat cake which can be easily removed to a beaker by means of forceps. The crucible is also put into the beaker and treated in the usual way. The small amount which stays in the crucible is readily dissolved and the crucible is ready for another charge in a short time. This method is especially useful where there is a great amount of routine work to be done and the amount of platinum ware is small. It is not always necessary to use a nickel plate. I have used a plate of galvanized sheet iron of the same size. Such a plate can be used for many fusions, provided tests for tin and zinc are not made. Copper sheet will serve the same purpose in many cases. Care must be taken in all these cases that the plate is sufficiently cooled by means of the wet cotton or filter paper to chill the fused mass quickly.—*The Chemist-Analyst*.

L. VOGELSTEIN & Co. give the following figures of German consumption of foreign copper for the months January to March, 1912:

	Tons.
Imports of copper	54,645
Exports of copper.....	2,820
Consumption of copper.....	51,825

as against consumption during the same period in 1911 of 40,106 tons. Of the above quantity, 47,687 tons was imported from the United States.

NEED for a general knowledge of mineralogy by working miners was evidenced recently by the discovery of a 6-in. seam at the Lady Rose mine, Victoria, Australia. The miners regarded the material as worthless, since there was no indication of gold in it, and large quantities of it which had been broken were discarded as worthless. A visiting engineer recognized the material as scheelite, of remarkably good quality, worth \$400 per ton, much more than the gold-bearing quartz the miners were seeking.

PLATINUM producing properties in Colombia have recently been purchased by the Consolidated Gold Fields of South Africa.

Eastern Comment on Copper

THE SITUATION AS SEEN IN NEW YORK.

The copper situation has lost a large part of its interest for the public for the reason that it is now conceded on all sides that the control of the present coterie of men is so complete that natural conditions are no longer a dominant factor. While there is no copper merger as a tangible organization, yet to all intents and purposes the same end is secured. There is no longer any question of control, and the only topic of discussion is whether or not the present controlling interests have been obliged to take on a heavy load of copper in order to accomplish what has been done. The Copper Producers' report, which appeared this week, was ignored so far as market action is concerned. The April statement shows an increase in accumulated stocks of approximately 2,750,000 lb., with a copper surplus on May 1 of 65,066,029 lb. The market for copper is at the moment a little easier, around 16½¢. per pound, with the copper producers declaring that they are firmly opposed to any further advance in the price. Some well known copper authorities are predicting an 18¢. copper market, but it is hard to believe that the people now in control of the market, headed by John D. Ryan, would permit any such advance.

W. E. Corey, former president of the United States Steel Corporation, now one of the prominent figures in the copper world, is on record in a recent interview as considering Mr. Ryan the master spirit in control of the copper situation throughout the world. Certain it is that Mr. Ryan's work in copper has been a steady series of triumphs during the past three or four years, culminating in his work of a year ago abroad when he was apparently able to bring the copper people in England and on the Continent into line for harmonious action with the producers on this side. As to the outlook for the coming year, while the world's production is increasing, the fact that the situation is so completely in hand apparently removes all portent of danger from this source. An examination of results shown by the large producers during the first quarter of the current year, as compared with last year and the year preceding, shows a very general and substantial increase in output. The rehabilitation of many mining properties of importance has made this result a foregone conclusion for some months, and were competitive conditions the same as prevailed a few years ago there would undoubtedly be some record-breaking shipments from Butte, and from the mines of the Southwest. There was a good deal of discussion occasioned by the fact that there were heavy sales of copper during the month of April, while exports as shown by the figures for the month were much lighter than in March. One of the principal reasons for this apparent discrepancy was the strike among the stevedores at Baltimore, where loadings were much curtailed.

Referring again to Mr. Ryan and his work in the world of copper: This gentleman has returned to New York from a long trip throughout the West accompanied by a party of the more important of his associates. In Butte Mr. Ryan gave out a statement to the effect that men in the party expected to expend \$12,000,000 in Montana in the next year. Part of Mr. Ryan's statement was to the effect that Butte would show greater prosperity in the next twelve months than during any similar period in its history. Some skeptics might feel justified in questioning this statement, as Butte has come to be so very largely a 'one-company' district that any spread of general prosperity is by this very condition largely precluded. While Mr. Ryan was in Butte he held several conferences with R. L. Agassiz, vice-president, and James MacNaughton, general manager, of the Calumet & Hecla. The meeting and the interviews gave rise to a rumor that some changes in the Calumet & Hecla control were impending. The rumor has been emphatically denied and is undoubtedly without foundation, though it must still be considered a long step when the Boston-Lake Superior copper interests

are seen to be working hand in hand with the porphyries and newly developed mines in the far corners of the globe, such as the new mines in Alaska and Braden and Ferrobamba in South America. The Lake country is turning out a record amount of copper. It is said that there are no copper supplies at Houghton, and that many ingots are put into the cars before time has been allowed for them to cool.

The Shannon Copper Co. announces that it is about to pattern after the Rio Tinto and treat some of its semi-oxidized ores by a leaching process. The general manager of the Shannon, J. W. Bennie, was for some years chief chemist for the Rio Tinto in Spain, and he has patented a process which it is believed will allow the Shannon to successfully and economically treat some 3,000,000 tons of partly oxidized ore which it can extract at a very low cost, and the copper produced can be laid down in New York at not more than 9¢. per pound. The Shannon also has something like a million tons of tailing from the concentrators which will be treated by the new process.

The directors of the Granby Consolidated have approved the plans for a 2000-ton smelter to handle the ores from the Hidden Creek property and have made appropriation from the next year's earnings of \$500,000 to cover the cost of equipment and development. The question of financing the erection of the smelter is temporarily postponed, and expenses, so far as possible, will be met out of the combined earnings of the Granby and the Hidden Creek properties. Part of the \$500,000 will be expended in the construction of docks and a railroad of a mile and a half in length to connect the docks, the mine, and the smelter.

The market expects to receive plans in the near future for some new financing by the British Columbia Copper Co. Some additional mining ground, known as the Voight property, was taken under option something under a year ago, and, development work having proved satisfactory, it has been decided to complete the payments under the option and also to erect a new smelter. An issue of convertible bonds will in all probability be made. The prosperity which the British Columbia Copper Co. has enjoyed since it resumed operations late last year is largely due to the high gold content which it has been recovering. The copper ores of the British Columbia, like those of the Granby, are of very low copper content running about the minimum limit of commercial value, but owing to the precious metal, the company has been able to lay down refined copper in New York at 8 cents.

Kurnal R. Babbitt was elected a director of the Utah Copper Co. at the recent meeting, to succeed the late Ernest Thalmann. Mr. Thalmann was the head of the house of Ladenberg, Thalmann & Co., and one of the prominent figures in Wall Street. Mr. Babbitt has been an associate of Messrs. Jackling, MacNeill, and Penrose for many years and is the working law officer of the Guggenheim organizations. The important development at the recent meeting of the Utah Copper Co. was the statement by the engineering staff showing ore reserves totaling 300,000,000 tons. According to unofficial statements, it is believed that 200,000,000 tons can be added to these figures. With a total ore reserve of 500,000,000 tons of ore, the Utah Copper would have a life of nearly 100 years. The magnitude of the operations carried on at the Utah Copper Co.'s plant precludes any possibility of its equalling the Rio Tinto in length of years, but it stands at the head of the world's copper mines with a wonderful record in the way of its being brought to its present point of production in so short a time. The recently published list of shareholders shows the Guggenheim Exploration Co., the Bankers Trust Co., and W. J. Yates as the three largest shareholders. The Bankers Trust Co. is the trustee for the French investors. The Guggenheim smelter which is being erected at Hayden, Arizona, to treat the ores of the Ray Consolidated, has so far progressed as to have the stack completed. It is expected to handle regular shipments from the Ray next month. L. Vogelstein & Co. in a circular letter speak of the copper market as in equilibrium and likely to remain so for some weeks.

Discussion

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Insertion of any contribution is determined by its probable interest to the readers of this journal.

Statement of Construction Costs

The Editor:

Sir—The publication of a detailed summary of construction costs should serve one or more purposes. A system of bookkeeping should be indicated which could, with advantage, be adopted elsewhere either entirely or in a modified form to suit local conditions. The summary should be arranged so that an engineer would be able to isolate the totals for future reference as to construction costs in that, or in a similarly situated locality. The statement should appeal to him, as well as to the bookkeeper, as being logically arranged. In your January 6 issue a detailed summary of the construction costs at the new Portland mill, Cripple Creek, is published. In this summary there are 27 main divisions of cost, each of which is capable of dissection into 31 subdivisions, thus providing for a statement of 837 possible totals. The ledgering of such a system must have involved immense labor, and I am venturing on a criticism, from all points of view, in the hope that I may initiate a discussion on the matter which may result in the general adoption of some simple system which would, even in a summarized form, afford information of considerable value to mining engineers. With such a system in general use I venture to predict that much more data would be available as to the costs of mill construction.

In the statement referred to there is an obvious need of some sort of explanation, and even the primary division of expense calls for comment. Such headings as 'chemical,' 'solution,' and 'engineering' are too vague to convey any definite idea as to what is implied. Our curiosity as to the type of plant erected is excited, but by no means satisfied. The \$804.97 of 'tank steel' charged to 'coarse crushing plant,' and \$855.97 of 'belting' to 'classification' are equally inexplicable. The 'wire' account is difficult to place and cannot include leads to motors, because there are 13 departments with motors, and only 6 entries for 'wire.' In the search for ideas as to what 'solution' is meant to include we find in the statement \$37.87 for 'paper,' \$169.12 for 'lath' and 'plasters,' \$2.38 for 'powder,' and \$48.47 for 'skylights and windows.' Surely no statement of cost could be more enigmatic to a metallurgist. On the other hand, our sympathies go out to the superintendent whose house, according to the accounts, possesses neither skylight nor window. Let us hope that the doors are there, and have been charged under 'miscellaneous.'

The itemizing of small amounts in a summary is a practice open to question, but 'consistency is a jewel,' and I can see no logic in the entry, for example, of a total cost of \$0.61 for 'hardware' in the 'transformer house' account, when the total charges to 'miscellaneous' and undistributed expense together amount to over \$25,000.

Under 'precipitating' is seen a 'machinery' expenditure of \$15,686.80, an amount higher than in any other department. Under 'motors' the highest expense was incurred in the 'agitating' department, and amounted to \$1901.14. From the inclusion of 'pumps' and 'pipe' in the latter account it would seem that centrifugal-pump agitation is being adopted, and the result is awaited with interest. In the 'conveying department' it seems that \$1132.26 of 'shafting' are necessary to run a \$378.46 conveyor. Surely 'shafting' might go under a special power account, and a total for 'conveying department' include only the original cost of the conveyor and sundries, and the expense involved in erecting it. 'Radiators' and 'pipe' are charged to 'heating plant.' Why not 'shafting' to 'power plant'? Where power is taken off the same line of shafting in different departments the correct proportion of construction costs is an impossibility. The dissection of 'lighting,' 'heating,' 'superintendence,' etc.,

are equally impracticable, and separate accounts are indicated as the only possible means of arriving at a logical statement of expense.

As regards the inclusion of 'belting' in a statement of construction costs it must be remembered that, if this is done, the belts so charged are expected to last the life of the mill; and a proportion of the original outlay, a capital expenditure, would be written off annually under 'depreciation.' To charge original belting to construction, and renewals to working cost, would necessitate expert figure juggling to hide a rise in operating expense when none had actually occurred.

In order to promote further criticism and discussion I am adding three blanks and a summary, as suggestions, which can readily be adapted to suit local requirements.

1. CONSTRUCTION OF BUILDINGS ACCOUNT

	Labor	Lumber	Mortar and concrete	Structural steel and rivets	Roofing and walling material	Paint	Sundries	Totals
Mill building								
Power-house								
Machine-shop								
Assay office								
Totals								

2. CONSTRUCTION OF TREATMENT PLANT ACCOUNT

	Labor	Plant and machinery	Lumber	Mortar and concrete	Structural steel and rivets	Piping and flanges	Sheet iron and steel	Sundries	Totals
Ore transport									
Breaking									
Crushing									
Flue grinding									
Classifying									
Dewatering									
Agitating									
Conveyance of pulp									
Filtering									
Conveyance of solution									
Storage of solution									
Precipitation and smelting									
Disposal of residue									
Totals									

3. CONSTRUCTION OF AUXILIARY PLANT ACCOUNT

	Labor	Plant and machinery	Lumber	Mortar and concrete	Sheet iron	Pipes and flanges	Sundries	Totals
Power								
Lighting								
Heating								
Assaying								
Workshops								
Totals								

4. GENERAL SUMMARY AND TOTALS

Buildings account	
Treatment plant account	
Auxiliary plant account	
Superintendence, etc.	
Extra: road building	
Undistributed expense	
Total	

It will be noticed that cost of construction of the buildings is kept separate from the cost of construction of the treatment plant and also the auxiliary plant. Items incapable of dissection and distribution in a general statement, such as superintendence and road building, can be added to the summary. The analysis of such a statement is an easy matter, and the system may be used to form the

basis of a complete and detailed account of the various expenses involved.

London, March 9.

Magmatic Origin of Ore-Forming Solutions

The Editor:

Sir—On the question of 'Magmatic Origin of Ore-Forming Solutions' I have said in a paper before the Canadian Mining Institute, Toronto, March 1912 (not yet out of press):

"On the question of the genesis of ore deposits which has occupied so much of the discussion of the technical mining world for the last fifteen years, and referring to the controversy between the fire men and the water men as to which was the predominating agency in the deposition of orebodies, I have always regarded Professor Kemp's 'The Rôle of the Igneous Rocks in the Formation of Veins' (*Trans. Am. Inst. Min. Eng.*, Vol. XXXI, p. 169), as well-nigh the keynote of the situation. But in Nova Scotia, it must be acknowledged, is one of the exceptions, one of the few places where the deposition is not apparently traceable to an igneous source. Yet I would prefer to consider it probable that a laecolith or a high place in the granite existed at no profound depth beneath this tungsten deposit."

Denver, May 8.

VICTOR G. HILLS.

Spanish-American Dictionaries

The Editor:

Sir—Between the Rio Grande and the southernmost point of South America, as well as in the islands where Spanish is the native tongue, there exists an immense field for literary effort, which has practically been left unexplored up to the present time. There are schools, colleges, universities, military and naval academies, as well as sectarian institutions in Spanish America, wherein textbooks in the higher grades are in French, English, or even German; the reason being that the better textbooks have not been translated into Spanish. Works in English of the most important character, treating on mining, metallurgy, surveying, agriculture, hydraulics, irrigation, husbandry, medicine, manufacturing, industrial arts, and hundreds of other subjects, are not known, except to the learned few, in Spanish-speaking countries, and there can be no doubt that good translations would find a ready and immediate market. It may be a surprise to many that there is not even a complete up-to-date Spanish-English, English-Spanish dictionary on the market. Velazquez has had no revision at all since 1899, and then only a slight one, embracing the dropping of a few obsolete words and the addition of an occasional explanation. No attempt has been made to add the thousands of new words that have been added to the sciences, mechanics, arts, and manufactures in the past thirty years—some twenty-five years ago. Ponce de Leon published in New York a technological dictionary which is still being issued from the original plates. Pocket editions on special subjects have appeared from time to time, but up to the present no effort seems to have been made to publish a work that should be complete and up-to-date; such a work alone would, in a literary as well as a financial sense, be an unqualified success from the start. In 1910 the Latin American Union, at its annual meeting in Buenos Aires, adopted a resolution to the effect that such a work was a necessity, and had the Union had funds at its disposal for such a purpose it would no doubt have acted on the hint; as it is, the field is still uncovered; it is equally so with books on the important subjects of mining, mineralogy, assaying, and agriculture, as well as textbooks for the higher institutions of learning and works of reference for libraries. It would astonish some publishers, who cater simply to the home market, to find at what prices well translated standard works could be sold. So far a few Eastern publishers have confined themselves to sporadic efforts at introducing into Spanish America juvenile textbooks, with but indifferent success, due to the fact that this

class of textbooks is abundant enough in Latin America. Thousands of teachers write these and have them printed and adopted locally in proportion to the influence they have; they are not always of a high character, but serve.

In our efforts to open new fields for our industrial surplus the important subject of understanding each other's languages seems to have been neglected; notice how rarely a Spanish catalogue appears from even our large manufacturers, and a good Spanish catalogue is almost unknown. North Americans are keen after Spanish-American trade, but how many of the men are sent after it who know even the names of the articles they are sent out to sell?

The influence of literature between nations is great, it creates a harmony, an understanding between peoples who have been strangers—whose different languages were a gulf. If we would seek to acquire an influence over our Latin-American neighbors, let us study Spanish; if we want them to buy our goods, let us tell them at least their names in English and Spanish. This work is, of course, largely accomplished by manufacturers' catalogues, but the merchant, manufacturer, miner, agriculturist, and student needs, most of all, words of reference, books that are up to date.

San Francisco, May 1.

TRAVELER.

The Situation at High Grade

A few weeks ago, W. H. Storms, state mineralogist of California, published a warning to the public concerning the new mining camp, High Grade, situated up in the northeast corner of the state in Modoc county, advising those who might be induced to go there or to buy stocks in the numerous mining companies owning undeveloped claims in that district, to carefully investigate before turning their money over to the eager promoters. This warning was issued, not because no gold has been found at High Grade, for gold actually has been found there, but because the entire county was covered by snow early last winter and is still under the snow, which is still several feet deep. Naturally, promoters do not like interference of any sort in their plans, and particularly official interference. One of those who takes umbrage is N. E. Guyot, frequently referred to in the attractive literature concerning the district as 'the father of the camp.' Mr. Guyot has sent the following letter to Mr. Storms. It is of such nature that it needs no reply.

Sir—Your letter, 30th, at hand. The History of your life does not interest me. All there is to your letter appears to be solicitude you express for the welfare of the 500 men attracted to High Grade by my efforts. Leave that to them for I shall be with them. Are you so ignorant that you do not know that I warned miners in search of mere *work* not to go in? That I notified all of the deep snow? That those now there went of their own volition with full notice of the fact that it is a wilderness of splendid possibilities? They go as all mine operators and prospectors do, prepared to tight hardships. Spare yourself any uneasiness on that score for they are my friends. Re Denver *Mining Record* and their advertisers, settle your grouch with them. If all advertisers from cradles to coffins were indicted for the rainbows they attach to their particular products, you would have them all in the stocks. I know of no other business, however, which is cursed by a self-constituted inquisition which arrogates to itself the functions of prosecuting attorney, jury, judge and court of appeals, such as the mining business is inflicted with in yourself. As if your ilk has not turned down and blackmailed every new camp. You are so infallible, you scribblers, you repeat your advice to me to "adhere to the truth." You ineffable, nincompoop and immeasurable, irresponsible blackguard in office. It is a dirty bird that fouls its own nest and you have assuredly, unwarrantably defiled your own state of California, by denouncing, in ignorance, the greatest gold camp discovered in the state for 50 years. Burn these remarks into your petrified brain. Yes, you shall hear from me again. Yours truly,

San Francisco, Cal., May 10.

N. E. Guyot.

Special Correspondence

NEW YORK

NEWS NOTES FROM MEXICO, ARIZONA, BUTTE, AND COBALT.
—TACOMA SMELTER.—HEINZE AGAIN.

While many of the mines in Mexico are closed down or fortified to withstand a siege, the Greene-Canauea is unmolested and production is increasing regularly from month to month. Mr. Thornton, general manager, states that the company will in a short time be turning out 10,000,000 lb. copper per month. The Mines Company of America is one that has found it impossible to continue distribution of earnings. The regular quarterly dividend has been deferred. The stockholders are left to draw their own conclusions as to just what this means. Inasmuch as they will not receive the usual check, the distinction between synonyms is bootless.

N. L. Amster, president of the Shannon Copper Co., has purchased the R. R. R. copper mine near Patagonia, Arizona. The Three R's, as it is commonly known, has changed hands a good many times. At one period the late W. C. Greene held the property under option. The recent owners were persistent in trying to develop the property against the advice of engineers who examined the ground, and recent reports show their faith to have been apparently justified. Telegraphic despatches report the opening of a large body of copper glance such as was found in the early days of the Copper Queen.

The rumored merger of the American Zinc, Lead & Smelting Co. with the Butte & Superior is officially denied. Both concerns have been doing some new financing through the house of Hayden, Stone & Co., but apparently there is to be no consolidation. The issue of convertible bonds made by the Butte & Superior has all been turned into stock. The new concentrator of the Butte & Superior is just about ready for actual work, and by the end of June the property is expected to be producing 1000 tons of ore daily. The present orebody of the Butte & Superior is reported to be one of the richest zinc and silver orebodies ever discovered in Butte.

Cobalt is apparently well past the peak of its load. At present there are only six properties shipping, and the output is much lighter than has been the case at any time since the production was fully under way. The Kerr Lake Mining Co. has held a special meeting of its directors, and Julius A. Lewisohn was elected president of the company in place of Edward Steindler, deceased; and Wm. G. Nickerson of Boston was elected to the board of directors. At the annual meeting of the Nipissing Mines Co., August Heckscher, one of the controlling factors of the New Jersey Zinc Co., and who is also heavily interested in the oilfields of Mexico, was elected a director to succeed Wm. B. Thompson, of Thompson, Towle & Co., resigned. Mr. Thompson is the head of the Inspiration Consolidated Copper Co. and has been prominent in the development of mining properties throughout the Southwest during many years, having had a large share in the development of the Cumberland Ely, which was afterward absorbed by the Nevada Consolidated, in which latter company he is still a director.

The importance of the Tacoma plant of the Guggenheims is increasing. During the past eleven months the Alaska properties have shipped a total of 35,000,000 lb. copper, nearly all of which has gone to the Tacoma smelter; the bulk of the shipments coming from the Morgan-Guggenheim Bonanza mine. The market in First National Copper has been recovering a little, owing to the installation of another device to control the sulphur fume from the smelter. It is believed that the smelter can be again blown in within a few weeks. Nevada Consolidated has been a market feature during the past fortnight, and rumors have been active to the effect that the Utah Copper Co. intended to renew its offer for exchange for Nevada Consolidated shares, and there has also been some talk of an intended increase in the Nevada Consolidated dividends. It

is officially stated, however, that neither rumor has any foundation, and that the only reason for the sharp advance in Nevada Consolidated in the market lies in the improved conditions in the metal market. Nevada Consolidated produced 17,578,000 lb. of copper during the quarter ended March 30, and earned \$1,233,768, as against \$1,012,729 for the corresponding quarter of 1911.

Copper curtailment received a little setback from the U. S. Geological Survey report, just issued, covering 1911, which report gives the output for the year as being the largest in history, and figures the total smelter production from ore mined in the United States at 1,097,232,749 lb. Having 'sidetracked' the negotiations conducted for a time with Phelps, Dodge & Co., the Shattuck-Arizona company is to immediately proceed to build a 400-ton smelter at or near Douglas, Arizona. The Heinzes are having an exceedingly hard time to retain their hold on any of the interests which they at one time controlled. Some two years or more ago F. Augustus Heinze fell into the hands of one A. D. F. Adams of Boston, a loan broker whose business it was to make loans on unlisted securities having an active market, thereupon immediately selling out the stock so pledged with him. In carrying forward these transactions Adams used stock brokers who themselves acted in good faith, and for the past two years Heinze has been endeavoring to secure the return of a large amount of Davis-Daly, Ohio Copper, and other shares which he pledged with Adams, but by a recent finding of the Master in Chancery it is found that he has no right to make claim on the stock in the hands of innocent purchasers.

SILVERTON, COLORADO

FRISCO MILL.—SUNNYSIDE ZINC MILL.—ESMERALDA LEASED.—RICH ORE IN CONGRESS.—CHAMPION RESUMES DEVELOPMENT.

Mining affairs in San Juan county already show considerable improvement and the summer promised to be an active one. A number of properties long idle have already resumed operation, and many others are planning to do so in the near future. The Frisco Mines Co., owner of the Bagley adit at Animas Forks, is rushing work on a 150-ton concentrating mill. The timbers are being framed in Silverton and the structural steel and machinery are in transit. All materials will be transported to the mine and set in place as soon as the railroad is cleared of snow. The work is under the direction of Charles Gagner as manager and Paul Hansen as mill superintendent. The Sunnyside at Eureka keeps up a maximum production and the new zinc-separating plant is reported successful. Lessees are working the Esmeralda on a small scale, with no ore shipments yet. The Mildred group, in Maggie gulch, is being developed under the direction of Finney Jones, and employs 20 men at present. The intersection will be started at an early date, and the mill capacity will be doubled by the addition of five stamps. The lessees expect to treat 30 tons daily during the summer. The Iowa Tiger Mining Co., lessee of the Iowa and Tiger mines, is milling an average of 3000 tons per month and has an excellent body of new ore in the north drift on No. 2 level of the Melville lode. The Silver Lake is running two shifts and is pushing development on the Tinsville lode, with promising results. The Silver Ledge is being unwatered and is being examined by engineers in the interest of New York people. It is announced that systematic development will be carried on in an effort to open the hoped for orebodies of this mine, which have been partly mined on the upper levels. Lessees on the Congress mine at Red Mountain found a fine body of ore May 3, which shows 5 ft. wide and averages 0.78 oz. gold, 9 oz. silver, and 20% copper. The lease is owned by H. B. Maris and F. B. Goudy, of Silverton, and the owners are pushing development and expect to ship at least 25 tons of ore per day during the summer. The Champion mine, near Silverton, owned by the Ross M. & M. Co., is again active and is being developed through the Pittsburg adit, under the direction of Mr. Bryce, of Pittsburg. A force of 20 men is employed at present.

RHODESIA

CAM & MOTOR DEVELOPMENT.—MINING LAWS FOR NORTHERN RHODESIA.—ACTIVITY AMONG COPPER MINES.

Premature crushing has done an incalculable amount of harm to Rhodesian mining. Mine after mine in Rhodesia has failed, and failed lamentably, largely because of undue haste in the erection of plant and the commencement of crushing operations before any really adequate sort of development had been achieved. The directors and management of the Cam & Motor, operating in the Gatooma district, appear to be fully aware of this, and a thoroughly commendable policy of exploitation has been carried out in these properties. It is stated that there is now 'in sight' in the property well over a million tons of ore of a value of 52s. per ton. This must not, in the absence of more detailed and accurate data, be accepted as absolute. It is, however, certain that an amount substantially in excess of that blocked out at the end of September, namely, 700,000 tons of a value of 47s. 2d. per ton, is now developed. Not only have the directors been well advised and careful in the matter of development, but they have also acted in a commendable and cautious way in regard to equipment. The Cam & Motor ores are known to be somewhat refractory, and, accordingly, before proceeding with the erection of a

A SMALL RHODESIAN MINE.

permanent plant a small experimental installation has been utilized. According to London advices, the cost of the permanent reduction and treatment equipments will be £80,000. The working capital resources of the company at the end of June last amounted to £120,000 in round figures.

Hitherto, mining companies and prospectors operating in Northern Rhodesia have been at a distinct disadvantage because of the absence of any properly promulgated mining laws. This state of affairs is now being remedied. In order that those interested may have sufficient time in which to comply with regulations as to pegging, registration, etc., of establishing locations, warnings were some little time ago issued to principal holders as to forthcoming enforcements. The promulgation of this law will, of course, be welcomed, as it will give a security of title which has not hitherto obtained. A mines department is now being established at Livingstone, and the organization of the mining office is in hand. An acting secretary for mines has already been appointed. Such a course has been necessitated by the exploitation of the country and the increasing importance of some of the mines.

Northern Rhodesia is not to be compared with the southern provinces from a mineral-producing point of view. Nevertheless, some of the properties lying beyond the Zambezi river are of considerable potential value, and now that the territory is traversed by a railway line, evidences of real endeavor to bring certain of the Northern Rhodesian base metal mines to the productive stage are not lacking. The most famous is the North Rhodesia Broken Hill, which, on account of the complex nature of its mixed zinc-lead ores,

is still inactive, and recent ore shipments have only been small lots sent to England for experimental treatment. In regard to copper, however, much activity is being displayed. A smelting plant has been erected at the Sable Antelope mine in the vicinity of Kafue river. Last year copper from the neighboring Silver King mine of an estimated value of £251,000 was smelted at this plant. To the north of these mines the Kansanshi copper mines have four new traction engines running to the railway at Nikola siding, carrying a load of 22½ tons per trip. A new pumping plant and a new smelting plant have been installed. The Bwana M'Kubwa is also preparing to export fairly large quantities of copper. All these mines are situated to the south of the Katanga belt, where much trouble is now being experienced in regard to smelting.

DAWSON, YUKON TERRITORY

RECENT AMENDMENTS TO PLACER MINING ACT.

George Black, commissioner, has issued the following explanation of the recent amendments to the Yukon placer mining act:

The effect of the bill amending the Yukon Placer Mining Act passed at the session of Parliament just closed, and which amends sections 51, 74, and 75, is, as to:

Section 51. To prevent the grouping of claims other than adjoining claims, except in cases where such claims are part of the same operation or system of mining being carried on; and prevents the holding of isolated claims for speculation, the working of one or more of which will have no effect on the others.

Section 74. This section was intended to provide for the arbitration of disputes between the owners of claims, but in the original section no provision for a case where one of the disputants declined to arbitrate was made, in which event the section was found to be unworkable. The amendment empowers the gold commissioner to appoint an arbitrator to represent the claim-owner who refuses to appoint one for himself. There is nothing new in principle in the amendment. It merely makes the old section workable.

Section 75. The amendment to section 75 provides for the settlement by arbitration of the amount of damages payable to the owner of mining property which may have tailing, water, or other material dumped onto it by other operators.

BLACK HILLS, SOUTH DAKOTA

NEW RELIANCE SHUTS DOWN.—RICH ORE AT GOLDEN SUMMIT.—FOREST CITY MILL.—MICA PRODUCTION.

The dredge at Mystie is being overhauled and put in shape for operation after a shut-down since December. Some minor changes are being made, including devices for breaking up clay-balls that are found to carry off gold. The dredge was started last June, and the first season's operation was quite satisfactory, and even greater success is anticipated for the coming summer. Financial difficulties have caused the suspension of operations at the New Reliance property, on Annie creek. Officials of the company state that a speedy adjustment of all troubles will be made so that work can be resumed and advantage taken of the good weather which is now due. The property operated at a disadvantage during the winter months and costs were far above normal. Ten additional stamps were installed, as well as labor-saving features which have tended to reduce costs. Briquetting machinery is to be installed by the Gilt Edge-Maid company in its concentrator at Galena, so that a good product can be furnished the Black Hills Smelting Co. The Gilt Edge-Maid property contains a large body of porphyry ore carrying a high percentage of iron pyrite, with a small gold content. Its proximity to the smelter makes it attractive for fluxing.

The Titanic Gold Mining Co. has elected directors for the ensuing year, as follows: W. H. Bonham, I. A. Webb, and W. S. Elder, of Deadwood, South Dakota; E. Bright, Columbus, Ohio; and J. M. Rothwell, Martinsburg, West Vir-

ginia. The company owns a large acreage in the Carbonate district, and expects to resume work in the shaft early this summer. Del Canfield and associates have opened a body of ore in the Golden Summit property, near Hill City, that shows 2 in. of 'specimen ore,' worth on the average \$4 to \$5 per pound. This is being sacked and shipped to Denver, and the low-grade ore piled up to be treated in the mill on the property. At the Forest City property, near Hill City, work is progressing on the mill, and it is hoped to have the plant in operation within a few weeks. The mine shows 3 ft. of high-grade free-milling ore, and the mill contains 5 stamps and a concentrating table.

Harry Francis is operating a mica property near Keystone, having found a market for the product with a Wyoming company which manufactures asbestos goods, including shingles. A considerable amount of mica is used in these shingles. Mr. Francis is sorting the mica, and saving the larger blocks for shipment to Eastern consumers. The Mascot group, in the Two Bit district, is under bond to Denver people, and it is expected that a sale will be made. The Imperial company has paid to Lawrence county a little over \$10,000 in back taxes, and is preparing to resume operations. Nickoli Brothers have found a streak of ore assaying as high as \$178 per ton gold in a lease they hold on the Monarch property, in Two Bit gulch. The ore is being sorted and a good shipment will soon be made to one of the smelters.

BUTTE, MONTANA

OIL FLOTATION PLANT OF THE BUTTE & SUPERIOR.—DEVELOPMENT IN MINE.

The first unit of the 1000-ton mill being erected by the Butte & Superior Copper Co. is expected to be in operation by May 20, and the second 500-ton unit about a month later. Some ore has already been put through the coarse crusher, and the machinery has been operated for the purpose of smoothing it up, but otherwise the plant has not been operated. The management is confident that the new mill will make a good recovery by the oil flotation process, put in by James M. Hyde.

The mill is designed to treat 1000 tons of ore per day, and consists of a crushing plant, jigs, a hydraulic classification, a slime plant for oil flotation, and Wilfley tables, used only to separate the lead from the zinc. The ore is first reduced by rolls to 6 mesh, and after jigging, the tailing is reground to 40 mesh, and the tailing from the fine jigs ground to 100 mesh and treated by oil flotation. The pulp is thickened in settling tanks to three parts water and one part ore, and is mixed with a small quantity of oil and sulphuric acid and agitated. The gases generated by the acid from the carbonates in the ore, together with the entangled air particles from agitation in the mixing vats, forms a spongy pulp of sulphides which floats on the surface of the water, while the silica, which has no affinity for oil, drops to the bottom and is discarded as tailing.

The Hyde system has been used successfully by the Butte & Superior at the Basin reduction plant, owned by the United Copper Co., but the plant is antiquated and has not sufficient settling capacity to enable the Butte & Superior to treat its jig tailing. The rental for the Basin plant is also heavy, and for these reasons the Butte & Superior has been gradually closing down the Basin mill, and for some time has been shipping only 200 tons of ore per day, while putting 350 tons per day into a stock pile at the mine with the object in view of having a stock pile large enough to keep the new mill running continuously while a change in hoists is made, which is contemplated. The present hoist is now working to its full capacity, the mine being 1600 ft. deep, but the new engine, which is to be delivered in June, is designed for a 5-ton skip and with power to work to a depth of 3500 ft. Development in the mine during recent weeks has added greatly to the value of the property and ore reserve. The work is at present confined to the Black Rock claim, which is developed by a shaft 1600 ft. deep.

LONDON

YORKSHIRE METHOD OF SHAFT SINKING.—FINANCIAL POSITION OF AMALGAMATED ZINC.—RESULT SECURED.

A new method of sinking shafts through watery strata has been adopted in South Yorkshire, the system consisting of the use of steel piles. Steel joists were arranged vertically and their flanges were interlocked by intermediate members. These joists were then driven into the sand by a pile-driver that traveled round the circle. This method of interlocking steel piles is the specialty of the British Steel Piling Co., and is extensively applied in bridge, dock, and railway work. The present instance is its first use in connection with shaft-sinking. The steel joists were 33 ft. long at No. 1 shaft and 28 ft. at No. 2 shaft. They measured 15 by 5 in. in cross-section, and the interlocking members measured 6¼ by 4 in. The webs were slightly bent, so that when assembled the joists could be set up in a circle 26¼ ft. in diameter. When driving was commenced a 3000-lb. weight was used, and each joist was forced down 5 ft., the driving-plant traveling gradually round the circle. Toward the end a 4000-lb. weight was used, as it was desired to penetrate the sandstone for 3 ft. Each pile was then driven 1 ft. downward at a time, and as many as 1300 blows were required for each foot sunk. When the piles had all been driven, sinking was commenced. It was found that the lining was only 1½ in. out of plumb, and that the leakage was approximately 5 gallons per minute. Experience in other directions has shown that this method of sinking can be successfully employed to a depth of 100 ft. and that within this limit the cost and the time occupied in shaft-sinking through wet strata should be much less than by any other method.

A fortnight ago I announced the welcome news that the De Bavay and Minerals Separation flotation processes were to cease hostilities and that in future the controllers would pool the Australian royalties. It is therefore of interest to record the financial and industrial position of the Amalgamated Zinc Co. which controls the De Bavay process. The present company was formed in Melbourne at the end of 1909, and the business consists of treating the zinc tailing from the North and South mines at Broken Hill belonging to the same group. The company also secured the contract for the treatment of zinc tailing from the Block 10 mine, but this mine is not at present producing, owing to the reconstruction of the lead-concentration plant under way. The report for the half-year ended December 31 last shows that 256,454 tons of zinc tailing was treated, and the production was 75,587 tons of zinc concentrate, assaying 48.7% zinc, 6.6% lead, and 9.7 oz. silver, and 1408 tons of lead concentrate, assaying 53.8% lead, 16.8% zinc, and 32.2 oz. silver. The income was £264,728, part of which came from the sale of current zinc concentrate, the price of zinc being figured at £22 per ton, and the remainder from the adjustment of the account of the previous period, taking £26 11s. 7d. as the settlement price for zinc instead of £22. The balance of profit for the half-year was £122,291; out of this, £20,000 has been placed to the equalization reserve fund, £10,000 placed to reserve for depreciation, and £50,000 distributed as dividend. Since the end of the period under review a further £50,000 has been paid to shareholders. As with the previous period, there will be a further income for the past six months on the final adjustment of prices. For every £1 above £22, the company will receive £13,600 additional on the 75,587 tons sold.

Camp Bird, Ltd., has acquired a considerable interest in the Messina (Transvaal) Development Co., Ltd., and has agreed to guarantee the interest for five years on £350,000 worth of 6% debenture stock which is to be issued by the latter company.

Gold production in the Urals during 1911 amounted to 258,240 oz., a decrease from 1910 of 10,520. The most productive districts are Miask, southern Ekaterinburg, and the Kvarken mines, Orenberg. The Kotchkar goldfields of the Miask district have been worked ever since 1844, and have yielded over two million ounces.

General Mining News

ALASKA

KATALLA

The Amalgamated Development Co. is planning to sink a well on each claim before applying for patent. The company is now extending its refinery so as to make illuminating oil as well as gasoline, which latter is already on sale regularly at Valdez, Cordova, and other coast towns. The British Columbia-Katalla company is said to have raised \$300,000 in England to be expended in developing oil lands here.

KETCHIKAN

(Special Correspondence.)—Considerable activity in this district is anticipated this year as a result of the increased price of copper, but at present little is being done. The Mt. Andrew is temporarily idle, though Rush & Brown recently opened an orebody on the second level and shipped several hundred tons. At Copper Mountain an examination is being made on behalf of the owners, to determine whether the mine shall be re-opened. This company was formerly known as the Alaska Copper Co. In case it is decided to resume

COPPER MOUNTAIN SMELTER, PRINCE OF WALES ISLAND, ALASKA.

operations a reorganization will be necessary with, probably, the issue of new stock and a change of name. On the Prince of Wales island five men are at work and the Red Wing mines of the Prince of Wales, Ltd., at the Copper City on Hetta inlet, Ketchikan bay.

Juneau, May 1.

VALDEZ

The mosquito fleet was busy until recently, as prospectors and miners were rushing supplies into their camps before the trails softened. Now transportation is largely at a standstill till summer trails become available. A hoist, compressor, cars, and track for the Millard M. & D. Co. have arrived and will be sent to the Ruthertford-Ramsey as soon as possible. In the meantime sinking has stopped. About 400 sacks of ore are reported ready to bring out over the glacier. A mill test on ore from the Bruce & McDonald property on Shoup bay, yielded 14 oz. 12 dwt. gold from 5400 lb. of ore. Three additional Nissen stamps were put to work in the Cliff mill early in May and sinking from the 400-ft. level is in progress. The new building for the Valdez Iron Works on the municipal dock, is about ready for occupancy. The Valdez Mining Co., has asked for bids on a 225-ft. continuation of the lower cross-cut begun last summer. W. A. Dickey is erecting new buildings at the Three Man mine, preparatory to increasing the scale of operations this summer.

ARIZONA

COCHISE COUNTY

The Midnight, in White Tail canyon, 22 miles from San Simon, has been sold to G. H. Davis. The ore carries gold, silver, and lead, and averages \$50 per ton. The West Side group of claims has been bonded to Philadelphia people

for \$17,000, of which one-fifth is to be paid on June 9. A vein 80 ft. wide has been opened to a depth of 9 ft. and shows 3 to 4½% copper. H. E. Henderson has secured a lease on the Humboldt. Work has been started on the bins at the Maine. Hallum & Sutherland have sunk to a depth of 25 ft. on the orebody of the Leadville.

GILA COUNTY

(Special Correspondence.)—The Guggenheims have taken an option on the Needles group of 27 claims and 13 adjoining claims, three miles west of Miami. The Needles group is owned by Dan R. Williamson, and the deal was conducted by F. W. Hoar of Globe. It is proposed to explore the group by churn-drilling. George H. Garrey, mining geologist and engineer for the various Guggenheim corporations, will supervise the work of exploration, and Ralph C. Nowland, chief engineer for the Ray Consolidated Copper Co., will have direct charge of the drilling. After a month spent in examination and sampling, a group of Michigan men has obtained an option on the 600,000 shares of treasury stock of the McMillen-Stonewall Mining Co., which owns the Stonewall Jackson mine, 16 miles north-east of Globe, a famous silver producer thirty years ago.

Globe, May 9.

The Live Oak began shipping concentrate to Cananea on May 6. Machinery and supplies for the South Live Oak Development Co. have begun to arrive at Miami. Harry Millard will have charge of drilling operations. Three holes are being drilled on the Southwestern Miami, but they have not yet passed through the Gila formation. At the Inspiration a small force has been put to work underground. The survey for the site of the Inspiration Con. mill has been made at Salt river and that of the possible site at Black Warrior, two miles north of Miami, is being made. The attachment suit by the Cordova Copper Co. against C. W. Van Dyke, for \$15,365 loaned him, was decided in favor of the plaintiff. The Warrior Copper Co. is suing the Warrior Development Co. for \$69,000 damages.

MOHAVE COUNTY

The clean-up for the past four weeks from the Tom Reed mine yielded a bar worth \$71,000. The recovery for the year has averaged \$43 per ton in the 20-stamp mill, which has a capacity of 120 tons per day. At the Gold Road two more tube-mills will be installed and 20 stamps will be added to the 40 now dropping. The company is treating 200 tons per day with a recovery of \$15 per ton, and the changes will bring the capacity to 350 tons per day. It is reported that a Los Angeles corporation will begin work on a dam across the Colorado river at the mouth of Diamond canyon for hydro-electric power development. The Yucca M. Co. is unwatering its mine and will sink another 100 ft. in the hope of cutting the rich ore found in the upper levels.

CALIFORNIA

CALAVERAS COUNTY

The Esperanza, or Boston, mine is to be unwatered and the vein sampled. The shaft is 1000 ft. deep. Joe Handel is working the old Marlette gravel mine at the base of Stockton hill. The Petticoat mine has resumed work after two years of idleness. A. T. Copley is manager and J. E. King is superintendent. The Comet mine is working a full crew on a 3-ft. vein of high-grade ore. F. W. Boire and H. W. Seeman have cleaned up a thousand dollars from a short run at the Boire Brothers' gravel mine. They have bought a Cox pan and will put in a modern plant to handle the gravel. Retimbering of the Hexter adit has been completed.

KERN COUNTY

Frank McCabe has purchased the Tuber Canyon mining property, and it is likely that a new mill will be erected, as plenty of \$12 ore is available.

LASSEN COUNTY

Baker & Bidwell, of Denver, have been drilling placer ground near Moonlight, and it is reported that a dredge will be put at work.

NEVADA COUNTY

Suit has been brought against the Tarr Mining Co. and various water companies to prevent them taking water from Bear river and its tributaries in Yuba and Nevada counties. The ranch owners who have brought the suit allege that their riparian rights have been infringed. Much interest has been excited by the finding of two good veins in his back yard, by F. S. Hooker, of Willow Valley. F. E. Sipe, of Mansfield, Ohio, is engaged in opening the Rough and Ready. D. S. Donahue has found that 250 ft. of rock supposed to be barren at the Justice-Sound Money Consolidated mine, four miles northeast of Washington, has a good gold content. The California mine at Gaston is working 90 men, and a long and deep adit is proposed at the Erie. Sale of the Waldeck is contemplated and improvements are projected at the Artie. The new Oakman mill is now in operation. The Maryland Gold Quartz M. Co. has elected directors for 1912. L. V. Dorsey is secretary and treasurer.

PLUMAS COUNTY

The cyanide plant at Crescent Mills to work the tailing of the old Green Mountain and Crescent mines is in course of construction. E. H. Tracey is in charge. Sinking of the 450 shaft at the Altona is in progress, a 12-hp. gasoline hoist having been installed. There are three veins, ranging from 3 to 7 ft. wide, on the property, with an average gold content of \$11 per ton. The litigation over the Del Monte will be settled soon. Rich ore has been found in the Four Hills mine by Andrew Bachelis.

SIERRA COUNTY

(Special Correspondence.)—The vein in the lower adit workings of the Tightner has widened to 30 ft. and been opened a distance of nearly 400 ft. It is said the capacity of the 10-stamp mill is to be increased. Abe Hall is manager. Sinking at the Rainbow is progressing. L. P. Woodbury is manager. C. C. Derby has obtained control of the bond and lease on the Gold Canyon, and is arranging to operate the mill and mine plant with hydraulic power. It is stated the Sierra Power & Mining Co. has taken a five years' lease on the Butte Saddle mill. The Brandy City Hydraulic Co. has managed to keep four to six giants in action the greater part of the season, despite the light winter rains. George F. Taylor is manager. San Francisco people, headed by George W. Hegarty, have arranged to resume operations at the Irelan and Snow Point mines, Alleghany district. It is planned to erect a 5-stamp mill at the Irelan this summer.

Alleghany, May 6.

TUOLUMNE COUNTY

Sale of the App mine to the Tonopah Belmont Development Co. is announced at Jamestown. It is known that W. A. Nevills, some time since, gave a deed of trust for the property to a Los Angeles banker, and that San Francisco and Los Angeles associates of Mr. Nevills have been for some time pressing him to sell. The property was examined by engineers of the United States S. R. & M. Co. some months since, but for some reason the deal fell through. Later Frederick Bradshaw and other officers of the Tonopah Belmont company visited the property, and on completion of the examination the sale was announced. The App is a large, low-grade, Mother Lode mine which has a good record of production. The surface works are run down and part of the underground workings suffered within a year from a cave, but the property itself is considered good. The shaft is 1700 ft. deep and stopes said to be as much as 110 ft. wide are worked. There are sixty 950-lb. stamps in the mill. Amalgamation is followed by concentration as usual along the Mother Lode, and concentrate is shipped to smelters.

COLORADO

CLEAR CREEK COUNTY

(Special Correspondence.)—The Pennsylvania M. Co., operating the John L. Emerson and other properties on Bellevue mountain, is making ready to construct a large mill. Experiments are now being made to determine the

best method of treatment. L. Sternberger is manager. Machinery is to be purchased by F. L. Patriek, manager of the Dorit mine on Chicago mountain. A milling plant of 50 tons capacity is also being considered.

The Teller mine, a former producer of high-grade ore, is again to receive attention. J. Owen is manager. The Oneida mine is one of the heaviest producers in the district. Shipments of smelting ore average \$25 per ton in gold. A mill of 50 tons capacity will be erected during the summer. J. Owen is manager. Charles McCall, district judge, has granted an injunction restraining the Pewabic M. Co. from further work in a drift run from the shaft. The Old Town Con. M. Co. has filed suit asking for judgment in the sum of \$200,000, alleging that amount of ore was extracted from its ground.

Idaho Springs, May 10.

(Special Correspondence.)—The Cashier mine is again undergoing development. Chance & Co. is operating under lease and occasional shipments are going out that bring a settlement for 160 oz. silver per ton. Work will be resumed next week on the White property, situated on Columbia mountain. G. J. Hite is manager. The St. Paul M. Co. will begin development June 1. The adit will be continued 600 ft. to intersect the series of veins owned. C. D. Runkle is manager. Work has been resumed on the Welsh property, on Leavenworth mountain. Stopping is in progress on a 6-in. streak of \$90 ore. A pool of Silver Plume operators has taken a lease on the Vulean mine. A small streak of 350-oz. silver ore is showing.

Georgetown, May 10.

LAKE COUNTY (LEADVILLE)

The Leadville Mines Pumping Co. is sending out its contracts for signature. These provide that if 95% of the claim-owners of the Fryer Hill district sign, the company will at once install electric pumps and proceed with the unwatering. The royalties asked are reasonable, and if within thirty days after a mine has been unwatered the owners do not work a property or sublet it, the pumping company has the right to work it or sublet it until July 1927. In case the pumping company fails to do so within ninety days, the control reverts to the owners. The proposal is attracting much interest, and it is hoped that the united action can be secured which is essential to success. A new electric hoist is being installed at the Gold Basin, on Breece hill. The Small Hopes Consolidated M. Co. has been purchased by F. Zaitz and associates.

TELLER COUNTY (CRIPPLE CREEK)

The Elkton company has declared a dividend of 1c. per share, payable May 24. The net value of the ore shipped by the El Paso in April amounted to \$53,987. From January 1 to March 31 the earnings of this company were \$143,780. The lowering of the water in the district now totals 141 ft., the decrease during April having been 15 ft. During April the Ajax shipped 33 cars of average \$30 grade and the Gold Dollar shipped 36 cars of \$20 ore on company account. Fourteen sets of lessees are at work, and the total ore shipped was over 2000 tons. The Anchoria-Leland produced 15 cars of \$20 ore. The Acacia was shut down during the month, but royalties from lessees amounted to about \$1800. Edwin Gaylord, who has leased the Dante, on Bull hill, has started the erection of a mill to treat the low-grade ore. The Portland No. 1 shaft will be sunk to the 1600-ft. level, the water having receded 75 ft. below the bottom of the sump. The tonnage treated by the Portland mill at Victor during April was 13,000, though interrupted by a shut-down. The tonnage during May should reach 15,000.

IDAHO

IDAHO COUNTY

The American Mines Co., which is capitalized at \$500,000, and has an option on properties in the Salmon river country, has filed articles of incorporation. The construction of the roaster at the custom reduction plant is progressing rapidly and a trial run will soon be made.

B. C. Austin is examining the Mineral Zone mine, in

the interest of F. W. Bradley and associates, of San Francisco.

LEMHI COUNTY

The Idaho Tungsten Co. is erecting a 100-ton concentrator on its property at Patterson, sixty miles south of Salmon City. The company, which has a lease for seven years on 21 patented claims, last year built a 20-ton reduction plant and shipped a large quantity of ore. The upper adit is in 900 ft. on a 3½-ft. vein and the lower adit 250 ft. It is estimated by George Kessler, superintendent, that 36,000 tons of ore is blocked out.

SHOSHONE COUNTY

E. J. Carter has filed a petition for the appointment of a receiver for the Stewart Mining Co., alleging that F. A. Heinze has transferred a large block of the stock of the company to H. U. Hart without consideration, has dissipated the assets of the company, and converted its earnings to his own purposes. M. W. Bacon, Stanley Gifford, and L. Dunham are codefendants.

MONTANA

LEWIS AND CLARK COUNTY

Receipts of the United States Assay Office at Helena during April were \$158,649, an increase of more than \$33,000 over the receipts a year ago. Receipts from the different counties were: Madison, \$57,801; Fergus, \$41,425; Lewis and Clark, \$32,333; Chouteau, \$24,466; Missoula, \$1286; Granite, \$108; Park, \$52; Deer Lodge, \$10; Washington state, \$331.

LINCOLN COUNTY

(Special Correspondence.)—The Shaughnessy hill group of claims of the Hazel T. M. Co., eight miles southwest of Libby, on Granite creek, has found 10 ft. of clean shipping ore in an adit which has cut the vein at a depth of 300 ft. in a length of 640 ft. The ore is rich in silver and lead and the hanging wall has not yet been found. The Snowshoe mine and mill will be started up within a few days, according to the plans of William Jennison, the receiver, the property having been closed down since his appointment several weeks ago. Robert C. Davis, of Butte, is to have charge of the property as superintendent.

Libby, May 7.

SILVERBOW COUNTY

(Special Correspondence.)—The Davis-Daly Copper Co. is making good progress in the development of its property and in profit earning under the new management. The Colorado shaft has been sunk to a depth of 2000 ft. A small zinc vein was discovered on the 1700-ft. level, and has been opened again on the 1900, where the vein is still small but rich in zinc. The Davis-Daly company is shipping daily about 50 tons of ore to the Washoe smelter, the shipments being of first-class ore.

Fair progress is being made in driving the cross-cut on the 2000-ft. level of the West Gagnon to develop the Silver King and Plymouth veins at that depth. The work is being done by the Anaconda company under a contract with the Davis-Daly. The lessees on the east end of the Silver King are shipping some ore of fair grade from the 200 and 300-ft. levels. The Pioneer Leasing Co. has taken a lease on the Great Republic, one of the Davis-Daly properties, about 1000 ft. north of the old Blue Bird mine, west of the city. The leasing company has pumped the water from the old workings down to a depth of about 200 ft., and expects to have the mine fully unwatered soon.

Butte, May 13.

NEVADA

CHURCHILL COUNTY

(Special Correspondence.)—Development is being done, and ore is being opened up on all levels of the Nevada Wonder mine down to the 500, and preparations are being made to begin drilling on the 600. A cutting-out stope is being started on the second ore-shoot north of the shaft on the 400-ft. level. The mill is now handling its full capacity of 100 tons per day, and 18 bars of bullion were shipped as a result of the clean-up for the last two

weeks of April. Most of the machinery for the improvements which are being made to the mill is on the ground and some has already been put in place. No stopping of work will be necessary to complete the work.

Wonder, May 13.

HUMBOLDT COUNTY

(Special Correspondence.)—The litigation between the Mammoth National and Workman interests has been settled. Following the discovery of high-grade quartz in the Shively holdings, on the north side of Winnemucca mountain, a rush has developed and practically the entire mountain is staked out. Dyke, in the Pine Forest mountains, is attracting some attention. Rich streaks of gold-bearing quartz are reported near the surface. New machinery will shortly be purchased by the Sheba Mining Co., operating the old Sheba mine in the Humboldt range.

Winnemucca, May 11.

LYON COUNTY

The smelter at Wabaska handled 2632 tons from the Nevada Douglas, 1623 tons from the Mason Valley, and 655 tons from other mines during the week ended May 2, an average of over 700 tons per day. The shipment of copper matte to Garfield was 9 carloads. Most of the Nevada Douglas ore comes from the sixth level of the Ludwig where the ore has been averaging 4½ % copper, though the Douglas Hill and Casting Copper mines contribute to the output.

NYE COUNTY

(Special Correspondence.)—The Associated mill is running at full capacity of 50 tons per day on a 500-ton shipment from the White Caps. Operations will be resumed on a 1000-ton shipment from the Steffner lease as soon as the White Caps product is finished, to be followed by shipments from the Kendall-Douglas and other leases. Seven companies, the Big Four, Mineral Hill, Dexter Union, Toro Blanco, Amalgamated, Morning Glory, and Thanksgiving, are operating on their own account. It is reported that the Mustang, St. Patrick, Chipmunk, Red Top, Giant, and other companies are preparing to work. Placer mining is attracting renewed attention. About 30 operators are active, with operations extending over a distance of nearly four miles. A number of deals have been recently made whereby new interests have secured some of the most promising locations.

Manhattan, May 11.

WASHOE COUNTY

Mrs. J. W. Mackay and Clarence H. Mackay have given \$150,000 to the University of Nevada for the endowment of the Mackay School of Mines.

WHITE PINE COUNTY

The Ely Verdi company has just been formed with a capital of \$5,000,000. George Wingfield, L. L. Savage, S. R. Roberts, John Berry, A. P. Sawyer, M. R. Brown, and H. S. Anderson are the directors. The property owned by the company lies to the south of the Copper Flat pit of the Nevada Consolidated, and it is announced that development will be at once commenced. Shipments of Giroux ore to the mill of the Nevada Con. have averaged 31½% copper, which is unexpectedly high. There are persistent rumors that the Nevada Consolidated and Giroux companies may be merged. One section of the Steptoe mill is now devoted to the treatment of Giroux ore.

NEW MEXICO

OTERO COUNTY

Ore is being shipped to the El Paso smelter from the Sulphur Canyon mine, in the San Andreas, about 30 miles from Tularosa.

SOCORRO COUNTY

(Special Correspondence.)—The Oaks Company treated 145 tons in April from 128 ft. of development on the Pacific mine, which will be sufficiently developed to begin stoping within thirty days. At the Johnson mine, the full width of the new shaft is in ore, which is being transported to the Deadwood mill. Development was advanced 10 ft. dur-

ing the week at the Deadwood mines, and 325 tons of ore was mined. In the mill 22 sacks of concentrate and the regular precipitate clean-up was made. Especially good ore is coming from the 300-ft. level north. Approximately 5000 tons was milled during April by the Socorro mines. The level at the bottom of the winze in the Deep Down is being driven west in good ore. During the week the Ernestine M. Co. crushed 735 tons of ore, producing 58 sacks of concentrate and the usual zinc-box precipitate. The last ten-day clean-up in April yielded 10,135 oz. of bullion and 9800 lb. of concentrate. During the month of April 3000 tons was milled, producing 28,700 oz. of gold bullion and 31,000 lb. of high-grade concentrate. This property is now producing every 50 days the price paid for the Last Chance mine by the present owners.

Mogollon, May 7.

UTAH

JUAB COUNTY

Numerous cave-ins in the workings of the Iron Blossom have occurred recently, and the latest, in the No. 1 shaft, has considerably delayed operations, and is likely to do so for a week more. From the No. 3 shaft 100 to 150 tons per day can be hoisted. The cave-in occurred in the adit through which the ore is transported to the Eureka Hill railway. The directors' meeting of the Lower Mammoth was held on May 9. Development is in progress at the mine and conditions are but little changed. Encouraging reports are received from the May Day, where good ore has been found on the 1000-ft. level. The shaft of the Tintie M. Co. is down over 100 ft. and will be continued to the 500-ft. level. Good ore is being found in the Opohongo. The Mammoth M. Co. has secured an injunction against Werrot & Orton, who purchased the McIntyre dump, as it was thought at the time of the sale that the dump contained but 4000 tons and now proves to be over 9000.

SALT LAKE COUNTY

The Utah will place the tenth and eleventh sections of the Arthur mill in commission about May 20. The Ohio Copper Co. reports satisfactory results from its mill.

SUMMIT COUNTY

The work of remodeling the old Ontario mill is being hastened by the Mines Operating Co., which is controlled by G. H. Dern, the manager of the Consolidated Mercur Gold Mines Co. The mill is intended to handle the low-grade ore which was used as stope filling by the early operators. It is estimated that 700,000 tons of a gross content of \$6,000,000 is available. The company has a ten-year lease, and the reconstruction of the mill, which will have a capacity of 150 tons, is expected to cost \$125,000, though the capacity may be doubled later. Small quantities of ore assaying \$15.17 per ton are reported from the East Ontario. The Daly-Judge has issued its quarterly report, showing that from January 1 to March 31 18,319 tons of concentrating ore and 813 tons of shipping ore were produced; 5588 tons of lead concentrate averaging \$28.53 per ton and 184 tons of zinc concentrate averaging \$25.09 per ton were sold. The average milling cost was 71c. and the average monthly earnings \$27,700.

CANADA

BRITISH COLUMBIA

Shipment of 500 tons of galena concentrate from the Portland Canal M. Co.'s mill has been made to the Tacoma smelter. This represents the last month's run of the mill before closing down last winter. Development work will be undertaken on the Sullivan and Daly group on Salmon river. The Boundary district mines shipped 35,752 tons of ore to the smelters during the week ended May 10. Two-thirds of this went to Granby and the rest to the British Columbia Copper Co. The total ore treated by these two smelters during this year is 650,000 tons. The Granby has shipped 7,500,000 lb. of copper this year. At the Rocher de Boule, near Hazelton, 15% copper ore is reported. J. F. Cowan is operating the property. A 150-

ton zinc concentrator will be built either at Three Forks or Zimeton by the Lucky Jim M. Company.

ONTARIO

A compressor will be installed at the Hughes mine and the shaft will be sunk to the 200-ft. level. Fuel is short at the West Dome, and some of the men have been laid off. The boat lines have resumed operations on the Mattagami river, and a road will be cut through Turnbull township and stopping places constructed. At the Hollinger 400 men are at work, and it is hoped to get the 40-stamp mill in operation by June 1. The No. 2 shaft has reached a depth of 50 ft. Rich ore has been found on the 200-ft. level of the Jupiter. The Crown Chartered shaft has reached 200 ft. in depth; work has been started on the Gold Crest. Shipments from Cobalt for the week ended May 4 constitute a record, amounting to 707 tons. The bullion shipments for the week were 105,000 oz. The total for the year to May 4 amounts to 2,853,459 oz., worth \$1,647,653; of this, the Nipissing yielded 1,292,485 oz. At the Buffalo mill 86,854 oz. of silver was recovered during March from 4007 tons of ore of an average content of 25.95 oz. Extensive diamond-drilling will be undertaken at the Dominion Silver, in North Cobalt. The Ophir Consolidated has resumed work. During April, 17 mines shipped ore, the total amounting to 1743.7 tons.

MEXICO

CHIHUAHUA

The Naica Mining Co., Lepanto, Gibraltar, Ramon Corona, and San Patricio companies are still operating, but the supply of dynamite is low, and unless a fresh consignment is received operations will have to be suspended in a few weeks. Thousands of tons of ore are piled up at the railroad station at Conchas, awaiting shipment to Torreon and Monterey, as the railroads are out of commission. Torreon is well defended by the Federal troops.

OAXACA

(Special Correspondence.)—The litigation concerning the San Juan mine has been settled between the heirs of Juan Baights and the San Juan Mining Co., by which the heirs relinquish all their right, title, and interest in the San Juan mine to the San Juan company, while the latter abandons all claims to the profits derived from the mine during the three years it was in Juan Baights' possession. This property, which is the deepest in Taviche, was acquired by C. A. Hamilton eleven years ago, but was subsequently occupied by the original owner, Baights, who in three years took out ore worth \$1,050,000. The property, to which the title is now clear, is valued at \$5,000,000. The property is shipping 2 cars of high-grade ore, and recently E. M. Hamilton examined it and recommended the construction of a cyanide plant, as some 200,000 tons of ore of too low grade to ship is available. Robert Wilson is general superintendent.

Oaxaca, April 29.

SONORA

The new smelter of the Richfield Copper Co., 45 miles east of Querobabi, has been completed, but its blowing in may have to be postponed until conditions become more settled. The Estrella M. & S. Co. has a shipment of high-grade ready to send to Cananea. The output of the Cananea Consolidated during April was over 6,000,000 lb. of copper, one day's output being 157 tons. Mining in northern Sonora is not much disturbed, thirteen companies having shipped 12,226 tons of ore and concentrate during April, but the smaller properties in the south have ceased operations, only the Mina Mexico and La Dura are at work in the Yaqui river district. The Dos Cabezas, in eastern Sonora, has recently closed down. The Alamos district is quiet, but La Mina Prieta has suspended operations on account of a broken cam-shaft, and will not resume until communications are reopened. The Southern Pacific railroad has suspended service on account of the depredations of Yaqui Indians, and practically all the Americans have left. Hundreds of mineral denouncements in Sonora have been declared forfeited for non-payment of taxes, and when peace is restored much land will be open to denouncement.

Personal

Professional men are invited to send news of their engagements and travels. Such news is interesting to friends.

AL PAGE is at the Palace.

F. L. SIZER has gone to Arizona.

E. A. MONTGOMERY is in Nevada.

GEORGE H. GARREY is in Arizona.

F. L. RANSOME has been at Miami.

GEO. A. SHEA is at the St. Francis.

R. E. HORE has gone to Poreupine.

EDGAR COLLINS is at Pearce, Arizona.

FREDERICK G. CLAPP is in Ontario, Canada.

A. J. OREM visited Salt Lake City last week.

J. A. BURGESS has been at Bodie, California.

W. G. SHARP has returned to Salt Lake City.

G. M. FRASER was at Salt Lake City recently.

GELASIO CAETANI has returned from Colorado.

J. E. CALLAHAN visited San Francisco recently.

E. D. BANNISTER visited San Francisco recently.

M. A. NEWMAN has returned from Los Angeles.

CALVERT WILSON was in San Francisco this week.

ROBERT M. SMALL was in San Francisco recently.

F. F. SHARPLESS is on his way to the Pacific coast.

E. H. CLAUSEN has gone to Quincy, Plumas county.

W. H. BLACKBURN is at San Francisco from Tonopah.

FREDERICK BRADSHAW was in San Francisco Wednesday.

EDMUND PUTNAM has returned to El Paso from Boston.

CHARLES JANIN is expected in San Francisco during the week.

WILLIAM MAGENAU has returned to Gomez Palacio, Durango.

C. H. WATERS has been drilling placer ground in Jackson county, Oregon.

ALBERT E. SEAL has left Tarkwa, West Africa, and is now in London.

RUDOLPH EMMEL, of Fairmont, West Virginia, is at Ludwig, Nevada.

C. EARL RODGERS is now at Sheep Creek, B. C., from McKenzie, North Dakota.

CHAS. P. RICHMOND is now with the Lluvia de Oro Mining Co. at Choix, Sinaloa.

G. N. PFEIFFER, who has been at O'Fallon, Illinois, is now at Hanna, Wyoming.

ALEXANDER FIFE, formerly of Waiki, New Zealand, is at Cobalt, Ontario, Canada.

ALTON L. DICKERMAN is now consulting engineer for the Old Colony Copper Company.

W. L. SAUNDERS will give the annual address at the commencement of the Colorado School of Mines, May 24.

T. IRWIN CROWLEY, of Mount Bullion, California, who has spent some time in San Francisco, is now at South Poreupine, Canada.

M. W. VON BERNEWITZ is leaving Kalgoorlie for San Francisco. He will visit the Eastern states of Australia and New Zealand on his way.

CONCESSIONS have been granted by the Madras Government, India, for developing alluvial gold deposits, and two mining engineers have been sent by Gowlo, of Calcutta, to conduct work on the Dilambur river.

RICH gold and copper deposits have been discovered at Chilposan, Phiyongsan district, Korea, by the natives, and work is now in progress, according to a Japanese report.

On Saturday, May 4, 1912, the Bunker Hill & Sullivan M. & C. Co. paid dividend No. 176 of \$65,400. This makes the total amount of dividends paid \$13,453,950.

METAL PRICES

(By wire from New York.)

NEW YORK, May 16.—Metal dealers are cheerful. The Copper Producers' statistics, announced May 8, made a favorable impression and caused heavy buying both here and abroad. Lead was also in somewhat better demand and sellers were not so anxious. Spelter is in excellent demand on account of the large consumption; there have been many sales and at advancing prices. Average daily prices for the past week, in cents per pound, based on wholesale transactions, standard brands, are given below.

Decisions Relating to Mining

Specially reported for the MINING AND SCIENTIFIC PRESS.

PLACER CLAIMS—ASSOCIATION LOCATIONS—MARKING BOUNDARIES

The unit of an individual placer-mining claim is 20 acres. But an association of persons may make a location of a tract which shall embrace as many individual claims of 20 acres each as there are individuals in the association, not to exceed eight locators making a location aggregating 160 acres. One discovery is sufficient to support the entire location of 160 acres. Where the boundaries were originally marked in such a way as to be readily traceable by a person making a reasonable effort to follow them, but were subsequently partly obliterated by fire, the original locators may restore their boundaries and will be protected against conflicting locations made by others prior to such restoration.

Hall v. McKinnon, (Alaska) 193 Federal, 572. December 4, 1911.

CHURN-DRILL HOLES AS IMPROVEMENTS

In an application for patent of several overlapping lode claims, it was sought to have churn-drill holes, made upon the overlapping portions of two claims, accredited as common improvements for each of the locations. The Commissioner of the General Land Office holds (subject to claimant's right to appeal to the Secretary of the Interior), that churn-drill holes are acceptable as individual improvements upon the locations upon which they have been sunk, but cannot be allowed as common improvements for each of the locations entered.

The Globe, Globe Fraction, and other lodes, Decision of Assistant Commissioner Prondit, April 26, 1912 (not yet published).

Note.—The Commissioner's decision is based on a ruling of the Secretary of the Interior in *ex parte* C. K. McCormick and E. W. Bird, dated March 14, 1912 (unreported), in which the Secretary holds drill-holes acceptable as individual improvements.

CONCLUSIVENESS OF PATENT-MEASURE OF EXTRALATERAL RIGHT

The owner of the Lucky Corner patented lode claim brought suit to eject an adjoining claim-owner from the extralateral part of the Lucky Corner vein. Defendant attempted to show that the Lucky Corner claim was located and patented without the discovery of any vein, lode, or ledge; that therefore it carried no extralateral rights; further, that the several veins in the Lucky Corner intersected its side lines instead of the end lines, that the side lines were not parallel; that hence no extralateral rights attached to the claim. It was held, however, that the Lucky Corner patent was conclusive in determining every question which was properly within the jurisdiction of the land department and was not open to collateral attack. The patent established conclusively the discovery of the apex of a vein in the discovery cut of the Lucky Corner claim prior to patent, and the patent was *prima facie* evidence that the discovery vein did extend transversely across the claim as patented. Whatever may have been the right of the defendant to raise the question, by protest, or other appropriate proceeding, of no discovery, prior to patent, that question was forever foreclosed when the patent issued except by a direct proceeding to set it aside or to have the patentee declared a trustee. The extent of the extralateral right depends upon the length of the apex, and it is measured not necessarily by the end lines—and only so when the vein passes across both end lines—but by bounding planes drawn parallel to the end lines and passing through the claim at the points where the vein enters into and departs from, the same.

The Work Mining & Milling Co. v. The Doctor Jack Pot Mining Co., (Colorado) U. S. Circuit Court of Appeals, March 2, 1912 (not yet published).

Concentrates

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

COLD BEND tests of steel are made to determine differences in ductility of different grades.

OPAL is found in Washington in lemon yellow to orange colors. When cut it is worth \$1 to \$1.50 per carat in stones of one to five carats size.

PRESSURE-FILTERS have the disadvantage of small capacity per charge, but this is overcome by the rapidity with which charges are treated. With a pressure-filter, also, there is no limit to the pressure that may be used, and hence to the closeness of contact of solution and mineral that may be enforced.

SEARLES LAKE, or Borax lake, as it is variously known, was discovered and located thirty years ago by Dennis Searles, who erected a crude plant and extracted borax from the waters at a time when the region was inhabited by hostile Indians. His cabin, surrounded by a stone wall for defense, may still be seen near the lake.

MONTANA sapphires occur in a variety of colors, and when cut form beautiful gemstones. The prices varies with the color and size of the stone. There are no regular quotations on uncut material, but recent offers of cut stones one to two carats in size are: blue, \$2 to \$30 per carat; straw colored, \$3 to \$10; white, \$2 to \$4.

ESTIMATING ore reserves requires the determination of the number of cubic feet per ton. In the case of iron ore this varies from 7 to 18, and in making estimates of Michigan ores, C. K. Leith used the following figures: Marquette hard ores, 8; Menominee and Gogebie ores, 10; soft ores of the Marquette, Crystal Falls, and Iron River districts, 12; low-grade high-silica ores, 14. The Oliver company uses the figure 10 cu. ft. per ton throughout, on the assumption that the error in this figure is considerably less than in assumptions as to dimensions of orebodies.

OIL for use in a blow-pipe lamp should be rich in carbon. Refined rape-seed oil is used for the purpose, as is olive oil, lard oil, and mixtures of turpentine and alcohol. The disadvantage of these is that they are not always easy to obtain and are objectionable in case the oil is spilled. For this reason, an ordinary small alcohol lamp is commonly employed, but it is impossible to secure a reducing flame from it. A candle is best for the reducing flame, but the ordinary 'short six' is too small to give a large enough flame. In some places large candles of about 2 in. diam. can be procured or, with an empty condensed-milk can to serve as a mold, and employing the smallest size of flat lamp-wick, they can be made with very little trouble by remelting ordinary candles.

CHROME ORE varies in price from \$10 to \$20 per ton, depending on grade of ore conditions and supply. According to E. F. Burchard, imported ore from New Caledonia carrying 50% chromic oxide was quoted in New York in 1910 at an average price of \$15 per long ton in earload lots, exclusive of cost of transportation. In 1909 the price averaged \$16.24 per ton. If the chromic oxide exceeds 50%, the value of the ore rises in proportion; if the chromic oxide is less than 50%, the value of the ore decreases at a more rapid rate. The price of the California ore is governed almost entirely by local conditions, as there is little or no competition with foreign ores. The price of chrome bricks f. o. b. Pittsburgh is \$175 per thousand. American potassium bichromate was sold at 73¢ to 8c. per pound, and the Scotch product at 10¾¢. per pound in the latter part of 1910.

provement in the statistical work of the Geological Survey. The preliminary statements issued at the first of the year are proving reliable and helpful. In many instances they are practically final as to total output, the work of the succeeding months being the more tedious task of tracing production to its sources. Accurate and prompt statistics are extremely valuable, and we extend congratulations on the excellent and timely tabulations now being published.

CONVERTER matte at the Great Falls plant of the Anaconda Mining Company has an average grade of 38.9 per cent, not 28.9, as we were made to say last week by a typographical error. The copper content of the matte is not an essential factor in the remarkably good work done at this plant, the criterion of success being rigid and accurate temperature control by skilled workmen. That the acid or basic character of a slag is dependent upon the ratio between the acid and constituents and not directly upon the percentage of silica present, as briefly discussed last week, is so generally overlooked, yet so important, that some elaboration of the topic will be worth while. This may be made clearer by assuming a slag in which the two bases present have greatly differing atomic weights, such as barium and iron. A bisilicate slag of these two elements ($\text{SiO}_2 \cdot \text{FeO} \cdot \text{BaO}$) might vary from 45 per cent SiO_2 , when only FeO is present, to 28 per cent SiO_2 when only BaO is present without changing its bisilicate character. To speak of slags over 40 per cent SiO_2 as 'high silica' slags and those below that percentage as 'low silica' is confusing, since a 'high silica' slag is not necessarily a silicious, or acid, slag. The terms 'half slag' and 'quarter slag' used in lead smelting are less objectionable, but it might be well for some of the workers on slag constitution to devise a new terminology by which the relation between molecular constitution and physical characteristics can be more accurately expressed than by the use of terms devised at a time when the nature of slag was a veiled mystery.

Metal Prices

Higher prices for metals have now obtained so long that producers have begun to recover from the shock of surprise and to ask why, and for how long they may be expected. That the steel mills are at last busy and copper has gone up has obscured the fact that spelter has been advancing for months. In keeping with the general disposition of that metal to be different, spelter prices began to rise when copper was still low. This year record prices have been paid for both zinc ore and spelter. In the week ended May 12, Joplin ore sold on a basis price of \$59 per ton for 60 per cent metallic zinc. This is \$2 per ton above the record of 1905, and \$17 per ton higher than the price for the corresponding week in 1911. Joplin production is now about 4500 tons per week, materially below former outputs during periods of high prices. New production at Joplin comes in slowly, and that from the West, in part because of lower grade of the ore, and consequently lower price, fails to make up for the deficiency. In the United States there is an admitted shortage in smelting capacity, a situation foreseen two years ago, but which, because of the then ruling low price of spelter and uncertain business conditions, it was impossible to forestall. When metal is high, the smelting margin favorable, and smelting capacity taxed, high-grade ores naturally have the preference, and Western zinc ores accordingly have not profited as much by improved conditions in the spelter market as was anticipated. When metal prices fall there will be renewed talk among spelter makers about the tyranny of the Joplin producers. By that time more retorts will doubtless be available and it will

be economical to handle the lower-grade Western ores. It is anomalous that high prices should favor high-grade ores, but it is a coincidence rather than a case of cause and effect.

A few years ago one of the ablest and best informed American mining engineers in privately discussing the future of the metals predicted rising prices for copper and lead, but stationary or falling prices for silver and spelter. The basis for his belief in low prices for the last named metals was the great accumulation of zinc-silver ore then just coming into the market from Broken Hill, Australia. On another page Mr. C. T. Durell, who has recently returned from that district, gives a glimpse of present conditions. Broken Hill has made good its claim to a place among the world's great zinc-producing districts. The annual output now amounts to 470,000 tons of concentrate containing 47 per cent of zinc. A recent estimate places the reserve at roughly 20,000,000 tons containing 18 to 20 per cent zinc. Whatever may be the accuracy in detail of this estimate, the Broken Hill district undoubtedly contains the greatest known reserve of immediately available zinc ore, and, as shown by Mr. Durell's figures, this ore is reaching the market in a steady stream. With the spelter is a parallel stream of silver and yet prices of spelter and silver are high, while, contrary to the expectation of the engineer who made the estimate, lead has benefited little by the recent increase. The reasons are not altogether clear, though some may be mentioned.

Expanding industry and cleaning up the scraps have put up the price of copper. Steel is also in good demand and, since half the spelter made is used in galvanizing, and because of their use in the same industries copper carries with it zinc, the high price of spelter is a natural consequence. Silver is high, and may be higher, because of the demand in the Orient. One steamer carried from San Francisco last week treasure to the value of \$2,500,000 and shipments to the Far East are steadily increasing. Direct exportation of silver from the Pacific Coast to China is not important as compared with the regular course through New York to London and on to Bombay. China, however, is now absorbing large sums, and both Western and Eastern ports are sending out the metal which is to be used in financing the new Republic. At present, promises to pay form the main counter current, but as industry develops bulky merchandise will follow.

Lead occupies an anomalous position among the metals in the American market this year. In part this is natural and in part artificial. As is well known, about 65 per cent of the lead business in the United States is in the hands of the American Smelting & Refining Company and affiliated concerns. Lead has been brought under control and 'stabilized' and the policy of valorization involves prevention of extra high prices quite as much as protection from low prices. The so-called 'trust' has perhaps more to lose as a consumer through a temporary orgy of high prices, than it has to gain as a producer of metal, and it is consistently playing the game. The natural factor is that consumption of lead has not expanded as rapidly as has that of the other metals. In the recent period of extremely low prices the one demand for lead that persisted came from the paint trade in the granger states. The farmers took advantage of the lull to paint their barns and fences and so, quite unintentionally, saved one 'trust' a bad half-year. Even Tom Sawyer, if we remember correctly, could not place an unlimited number of coats of whitewash on the famous fence, and the farmers' barns are all painted. The present revival of business has not yet taken the form of extensive building outside of the large cities, and it is where wood is the favorite material that paint is popular. In city houses, too, nickel plumbing is popular and tin has

long since superseded the sheet lead that our aristocratic grandfathers, assuming we are among the elect that had aristocratic grandfathers, once used for roofing. In truth, lead has lost some fields and has not crept into new ones as rapidly as the other metals. This is the natural condition that underlies the superficial control of the market. Despite appearances, fundamental conditions do control the metal markets in a broad way, and despite the sympathy between metals, each has a place and a market all its own.

High Grade and the Boom

The West has long been waiting anxiously for a boom in gold mining. Not that gold mining as an industry is not doing well, for in fact it is doing exceedingly well. The statistics show comfortable increases in production throughout all the Western states, and the progress of metallurgy is as rapid and significant as ever. Gold mining, however, is fast losing its luring quality and becoming a regularly established business. The big metal production of the West now comes from the big enterprises. Take out of California's gold production that won by the dredges at Oroville and Natoma, and that coming from four of the quartz mines, and the total has shrunk enormously. The same is true in most of the Western states. Idaho has large extent, but the Coeur d'Alene district contains the mines. Alaska furnishes lots of talk of quartz mining, but Douglas island ships the gold. This does not satisfy the West. No one becomes a pioneer to work in a factory, and the restless ones are not much interested in the established and the routine.

In Colorado they have a tradition that a great gold camp will be discovered every ten years, and, with a little twisting of history, Gilpin county, Leadville, the San Juan, and Cripple Creek can be marshalled into the approved order. Colorado hopes have alternately flickered and died down since Cripple Creek attained its majority, but when her own mountains remained obdurate, her citizens flocked *en masse* to the desert and contributed mightily to the making of Tonopah, Goldfield, and the new Nevada. Since the bottom dropped out of the Nevada boom and the mines of that state settled down to the prosaic task of paying dividends, the experienced boomers to whom typewriters and telegrams are better mining instruments than are drills and dynamite, have fallen on evil days. The public has been persistently and sadly apathetic and no boom has attained robust proportions; materialization getting no further than the haunting outline familiar to the spiritualist's plate. The boomers, however, have not been the only ones waiting. Paying dividends is tedious work, but it puts money into circulation and piles up surpluses. There has been less noise about Western mining in recent years, but more profit, and there are many men in the West who are now ready to back a legitimate venture. In our discussion column this week Mr. Victor Barndt tells of the spirit in which some of the successful men in Nevada and California are attempting to find potash deposits, and the instance he cites is typical.

Into this favorable habitat, and at the psychological moment, a party of experienced boomers have lit, and therefore High Grade has begun to grace the head lines. The typewriter and telegraph blanks have been called into requisition and the ad-writer is busy. Our Denver contemporary, *The Daily Mining Record*, is using its largest and blackest type to advertise EXTRA SPECIAL bargains in High Grade stocks, and you are informed that you will "have to hurry" if you are "to make your \$28.50 today worth \$75.00 next month." Remembering a long series of disappointments, the public has been a bit chary about accepting these

statements, and those, ourselves among the number, who have a favorable opinion of the district itself, are prejudiced by the advertising it is getting. Mr. W. H. Storms, State Mineralogist of California, has sounded a note of warning, mentioning the fact that the boom was started when the ground was comfortably covered with snow, when, as is well known, one claim looks as good as another—and is as good for purposes of capitalization. Opinion as to Mr. Storms' warning is divided. Mr. E. N. Guyot, 'the father of the camp' and a Cripple Creek prospector, replies in a scurrilous letter that fixes the status of the writer, and one Nevada paper, the editor evidently mixed in his geography, suggests that Mr. Storms stay in his own state and suggests "tearing him limb from limb"—a fine and useful phrase that in criticism. On the other hand, one Denver broker quotes in good 12-point Richelieu caps, Mr. Storms' statement that "there is no doubt that there is gold at High Grade, the principal property there at present being that of the Fort Bidwell Consolidated Mining Company, which has a ten-stamp mill. The camp will probably develop other good mines." Good advertising alone cannot make a good mine, though it helps any enterprise, but bad advertising may prejudice readers against a really good district, and part of the existing hesitation regarding High Grade flows from the transparent methods of the promoters.

As to the district itself there is much good to be said. An accurate and valuable account of it, including pictures of the principal veins now attracting attention, was published in the *Mining and Scientific Press* May 12, 1910. It was written by Mr. Norman C. Stines, and was based upon a careful personal examination. Following his report, the Fort Bidwell Consolidated Mining Company built a ten-stamp mill which was operated by Mr. Algernon Del Mar, and in our news columns there have been frequent references to the progress of the work. The reason this has been overlooked is that the newcomers have organized a new mining district and re-christened the camp. As the Hoag district in Modoc county, California, it failed to attract attention; but as High Grade, near Reno, Nevada, it is having fame thrust upon it.

According to Mr. Stines' report, the district is one of eruptive rock, including rhyolite, quartz andesite or dacite, andesite, and basalt. There are two distinct occurrences of ore; quartz veins in the basalt and andesite, and replacement deposits in the dacite. The former are 'gash' veins, small, rich, and erratic. The replacement deposits are large, of moderate grade, and contain persistent ore-shoots. All the ore is free milling and the ratio of gold to silver is 1 to 1.5. One ore-shoot on the Sugar Pine, seen by Mr. Stines, was "at least 150 feet long, with an average width as developed of 5 feet." Sixty feet west of it another ore-shoot had just been found when he visited the camp. The ore from the shear zones varies from \$7.50 to \$30 per ton in value. On the Big Four, Mr. Stines measured an ore-shoot over 300 feet long and averaging \$18.50 over 18 inches in width. The Sunshine vein, only about 10 inches wide, averaged more than \$100 per ton. Last fall at the completion of the work of the season, the Sunshine, Consolidated, and Big Four properties, could be fairly considered to have been proved to have value. Around them the field was one for prospecting. Now everything is staked, the known ground is largely leased, and the prospectors are on the ground. When the snow melts the final value of the district will be determined. We hope that the three known properties will prove to be but vanguards of a company of big mines, but the district is one for careful prospecting rather than the sale of stocks "certain" to be of large value. We wish it and its citizens the best of fortune at the same time that we refuse to take too seriously the statements of the more enthusiastic.

Culture in the Education of Engineers

By W. L. SAUNDERS

*At one of the meetings of the American Institute of Mining Engineers, held in the hall of Sheffield Scientific School at New Haven, a discussion arose as to whether or not sufficient importance was given to cultural studies in our scientific schools. A diagram was exhibited showing graphically the relative proportion that culture bore to other studies in the various colleges. In some there was a wide distribution of cultural work, in others the proportion was small, and in a few cases it was shown that these studies were entirely omitted from the curriculum. During recess, a group of students were discussing the subject; one of them, a senior, said, "I don't see why they should *learn* a person culture in a scientific school." This remark, made in my presence, so impressed me as a concrete example of neglect in true educational lines that it has been chosen as my text.

Education in its broadest sense is mental and moral training. High schools and colleges differ from common schools in that they aim at higher planes of mental and moral life. The small boy is taught by stuffing, as one puts sawdust in a doll; this is because his mind has not grown to the stage when it can think for itself. Impressions are received and transfixed by memory: the process is one of mental photography: the moral code is learned by rote as though it were the multiplication table. Not so with the older, the college student: his highest aim in education is to learn to think for himself. "If you are a student, force yourself to think independently; if a teacher, compel your youth to express their own minds," writes H. F. Osborn of Columbia; and again, "The lesson of Huxley's life and the result of my own experience is that productive thinking is the chief *means* as well as the chief *end* of education."

Now what is productive thinking? Let me answer this question by giving you Huxley's definition of culture: "The pursuit of any art or science with the view of its improvement." The storage process is of paramount importance only when applied to elementary education. It is but the handmaiden of the scholar who has passed from the junior to the senior stage of student life, and who aims to do things in the world. The pursuit of facts is a mathematical study. We learn of things that exist as a result of divine and human creation. The earth is round and it is composed of land and water: water is hydrogen and oxygen combined: the square of the hypotenuse of a triangle is equal to the sum of the squares of the other two sides. How elementary are these facts! It is important that we should know them; but even a large volume of facts when stored in the human mind is powerless to add one cubit to progress. It is like putting a pair of legs on the Encyclopedia Britannica and expecting it to do something. Knowledge is power, but reason is power in action.

James Gayley, of the United States Steel Corporation, told me recently that the professor at Lafayette College who taught him how to think made so deep an impression upon him that it has lasted throughout his life. Mr. Gayley is distinguished for what he has done as a metallurgical engineer. His life has been one of productive thinking; he has pursued science with the view of its improvement. That teacher, Mr. Gayley said, once gave him a solution containing iron, and instead of instructing him how best to precipitate the metal, he told him to try three or four ways of doing it and report which was best. This led directly to thought and reason, and built up a master mind among engineers. We may still heed the voice of old Carlyle crying from the heathery hills of Dunore: "Pro-

duce! Produce! Were it but the pitifullest infinitesimal fraction of a product, produce it in God's name! 'Tis the utmost thou hast in thee: out with it, then."

Where among all the professions do we get the results that come through productive thinking as from engineering? The engineer is the architect of the world's progress. Transportation in railways and ships, in motor cars and aeroplanes, is the productive thinking of mechanical engineers woven into our industrial life. The men who did these things were students of science, not that they might be mere storehouses of knowledge, but that they might produce. Civil, electrical, chemical, and mining engineering are fields which afford infinite opportunities for research and progress. If you men of the future do not rise to your chances in these lines it is not because the fields are not still open for cultivation and growth, but rather through your own inefficiency or top-heaviness.

"In vain our toil,

We ought to blame the culture, not the soil."

Even Huxley feared that men might be overfed scientifically when he said: "An exclusively scientific training will bring about a mental twist as surely as an exclusively literary training. The value of the cargo does not compensate for a ship's being out of trim; and I should be very sorry to think that a scientific college would turn out none but lopsided men."

All this bears upon culture in its broadest sense. Productive thinking is the most important form of culture. It makes for power, refinement, progress, knowledge, taste, civilization. The subject, you see, is a very broad one; the obligation upon you as students of science is equally broad. Take care that you be not 'lopsided men.' A graduate of the Colorado School of Mines, like all graduates of the higher institutions of learning, misses his opportunities and discredits his college if he does not carry throughout all his walks of life the imprint of the educated man. *Noblesse oblige* is a degree, and an obligation, which is uniformly conferred upon all college men. To carry this obligation properly, one should study culture in all its phases and in its broadest sense. Study it as an undergraduate and study it still harder and more fully through all your post-graduate life. To this end let us accept and profit by that definition of culture given by Mathew Arnold: "acquainting ourselves with the best that has been known and said in the world." A professor at Wellesley College defined culture as that which is left after all else learned at college is forgotten.

Virtue and moral training belong to cultural work in the education of engineers. It is a mistake to suppose that schools and colleges are places for mental training only. Physical exercise through athletics is just as much a part of one's college life nowadays as the study of mathematics; the one helps the other. Emerson said, "archery, cricket, gun, and fishing-rod, horse and boat, are all educators, liberalizers." To the engineer physical training is of value in order to fit him for out door work. Moral training is of even greater importance. Locke has placed virtue first in defining the objects of education. Wisdom he puts next, and then good breeding; last of all, learning. It is more the province of the teacher than of the student to safeguard and train the character by precept and example, for, after all, "the foundation of culture, as of character, is at last the moral sentiment. This is the fountain of power."

It is a common saying that manners make the man. Good manners afford us easy weapons with which to win friends and to conquer enemies. Manners adorn the gentleman and smooth the way of the educated man through the world. Manners are never born in men; but they

*Address delivered at the Thirty-eighth Annual Commencement of the Colorado School of Mines, Golden, Colorado, May 24, 1912.

are bred by association and study. Like oil on the journals of an engine, they avoid friction and aid efficiency. There are many reasons why we should be polite, but the best reason is because it pays; it costs nothing. It is said of William Earl of Nassau that he won a subject from the King of Spain every time he put off his hat. So engaging were the manners of Charles James Fox that Napoleon said of him on the occasion of his visit to Paris in 1805, "Mr. Fox will always hold the first place in an assembly of the Tuileries." "My gentleman," said Emerson, "will out-pray saints in chapel, out-general veterans in the field, and out-shine all courtesy in the hall. He is good company for pirates and good with academicians; so that it is useless to fortify yourself against him; he has the private entrance to all minds, and I could as easily exclude myself as him."

Good speech is a rule of manners. It always avoids exaggeration. Moderation in language and tone is the trade-mark of good breeding, and good breeding is, after all, mainly a matter of self-culture. Madame de Staël valued conversation above everything, and so engaging was she in that art, that a prominent lady of France said of her, "If I were Queen, I should command her to talk to me every day." The man of education mixes with the right kind of people and reads good books. Books lead us into pleasant paths of culture and happiness. Read that you may avoid worry; read that too much hard thinking may not dull the edge of intelligence and sap the roots of memory; read that you may know what has been done in the world; read that you may acquire that power which comes from knowledge; read that you may learn to value the example of great men's lives; that through them you may know that the grave is not the goal of life. Montaigne had a passion for books and never traveled without them; he said that reading roused his reason and employed his judgment rather than his memory.

But of greater importance than good speech and reading, of higher value to the engineer than manners, is ability to write good English. Engineers are not given to public speaking; they pride themselves in being workers; they compare themselves with General Grant, who did things. It is very true that the engineering profession is one of practical work; but no one can hope to achieve prominence in this profession who cannot write good understandable English. An engineer may not talk, but he must make reports; he must write letters; he should draw specifications and plans. To do these things properly, he must command and know how to use the tools of language. Lord Bacon tells us that "reading makes a full man, conversation a ready man, and writing an exact man." Engineering is an exact science; accuracy is the one column on which the whole structure is reared. To write clearly and accurately can hardly be called an accomplishment; it is really a necessity. No college course is complete, whether it be a classical, scientific, medical, or law course, without a thorough training in English. No graduate is worthy to be called an educated man who does not speak and write good English. It lifts a man above the common.

Margaret Fuller said that the object of life is to grow, and James Freeman Clarke has written a lecture upon this subject: 'Man's Duty to Grow.' A post-graduate course in self-culture will tend to upward growth. Such a course is open to every one. The greatest opportunities for that education which unfolds the whole nature of man are those which are opened when we close the college door behind us. Graduation only marks the beginning of education to one whose face looks forward and upward. Let us build high; "they build too low who build beneath the stars." Build so that life and strength and growth may vitalize the whole structure; build on lines that are straight; build so that every root and branch of the tree of knowledge lends support and does not add a twist to the whole; build that men may see in you not alone skill and wisdom, but honor, culture, manhood, example; study to improve self—

"For virtue only makes our bliss below,

And all our knowledge is ourselves to know!"

Flotation of Zinc Ores

By C. T. DURELL

No metal is receiving such world-wide attention today as zinc. No mining camp in the world produces so much zinc as Broken Hill, in Australia. The same reasons that have caused the phenomenal increase in the production of zinc in the past ten years will continue to increase the production for years to come and make the zinc industry a permanent and stable one. The present mountainous untreated dumps, as well as the immense ore reserves at the different mines, will continue to increase the zinc production of Broken Hill. Last year the world's production of spelter was upward of a million tons. Of this, Broken Hill supplied over one-fifth.

The 'barrier reef' at Broken Hill has been remarkable in many ways, having been worked in the early days of its history for silver. The camp is not quite as old as Leadville. Twenty-four years ago it was furnishing one-third of the world's silver production. The people of Broken Hill have the same cause for remembering the year 1893 as the people of Colorado. However, it was quick to recover, for in a couple of years it was demonstrated that the average grade of sulphide ores, of which there were millions of tons, would pay for treatment. This spelled prosperity with larger letters than before. Americans built treatment plants, as they had before mined these immense bodies of silver-lead-zinc ores. American machinery was introduced, and a close saving was made of the silver and lead, but the zinc went into the tailing. This country had no streams into which to turn the tailing, and, with mills treating from 500 to 1000 tons each per day, small mountains of waste soon accumulated which could be seen for miles across the desert.

Electric separators were introduced eleven years ago, and the tailing heaps, representing an expense account for stacking, at once became an asset. Experiments were being carried on with flotation processes, and two years later the first fifty tons of zinc concentrate won by flotation was shipped from Broken Hill. Last year there was produced 470,000 tons of zinc concentrate of a grade of 47% zinc. This was all extracted by flotation methods. During these nine years there was great competition between the flotation processes and the several methods of electrical separation. There is no question as to the rather startling result. The big plants of electrical separators are very conspicuous by their presence on the scrap heaps. Each and every one has been discarded, and the vast tonnage of zinc concentrate produced last year at Broken Hill was entirely by the four different flotation methods now in use there. A most excellent reason exists for the scrapping of these new and expensive electrical separation plants. It was the fact that from 10 to 20% more zinc was saved by flotation. Nor is the end yet in sight, for the Proprietary, the premier mine of the district, will soon have in operation a new flotation process for extracting the zinc from the slime which is at present being stored.

Not since the advent of the cyanide process has milling received such an adjunct as flotation, which has been termed 'concentration upside down,' owing to the fact that the sulphides rise and float off to the storage bins, while the barren gangue sinks and is drawn off to the tailing dump. The possibilities of this purely scientific process are just beginning to be understood, and Americans, usually in advance with new methods, have been eclipsed by the Australians. Concentration depends principally upon difference of specific gravity—degree of fineness of the crushing and dissemination of the mineral in the rock. In addition to these properties, flotation also depends upon form and lustre of the surface, capacity for the resistance of surface weathering, forms and dimensions of the crystals, and perhaps many less important and unknown properties. It is these properties that give rise to the surface tension effects upon which flotation depends. These vary even with similar ores, so that a flotation process in the hands of one,

unacquainted with these properties is sure to be a failure.

Anyone can concentrate sulphides in a gold pan and explain accurately just how they are saved. Everyone who has used a gold-pan has also seen the sulphides float instead of sink, but this surface-tension effect has only recently been brought into common use. Owing to the ignorance of the properties it is dependent upon, a few failures have been made in the United States. Failures occurred in Australia at first, but this does not detract from the wonderful and invariable successes of the present. At Broken Hill the Proprietary mine treats its own ores and tailing by a flotation process invented and perfected by the present manager. All the other companies have contracted, leased, or sold their tailing to separate companies organized especially to treat it by a flotation process.

Painting Cement Surfaces

To make oil paint adhere to cement, the surface of the material should be washed with diluted sulphuric acid (1 part concentrated acid to 100 parts of water), which afterward must be washed off and the surface allowed to dry, according to Herr Glinzer, director of the State Building School of Hamburg, Germany. Or the surface may be covered with diluted silicate of soda (water-glass), the solution to be 1 to 3 or 1 to 4, and applied three times. Still another method is to apply two coats of building 'fluat' at least 24 hours apart. Practical builders state, however, that they do not use sulphuric acid, and that such success as they have results merely from careful work and the use of good materials. Oil paint may also be applied to cement in the following manner: The surface is given one coating of linseed-oil varnish, to which is added a first coat of white lead when the varnish is dry. A second coat is then added, also containing white lead together with more or less coloring matter, as the building laws in Germany forbid the use of absolutely white paint on the exterior of structures. For wet climates the use of oil paints is recommended, as they are waterproof and present smooth surfaces which attracts a minimum of dirt.

Applied to iron, linseed-oil varnish when used by itself flakes off readily. It should be thoroughly mixed with red oxide of lead, 'caput mortuum,' or ochre graphite. This mixture serves as a first coat after the perfectly clean and dry surface has been gone over with the ordinary hot linseed-oil varnish. When the dead color has dried, another coat of the color desired is applied. The oil, being partly converted into resin, combines with the coloring material, making a thick coating that is the more impervious to water according as the color is finely ground or not. Lead should be used when the paint is exposed to water. The water colors so frequently used in Germany have, as a rule, silicate of soda as their base. These colors can be used on cement, plaster of paris, brick, or glass. Liquid casein paints are easily worked and are said to be durable. The discoloration of cement buildings frequently results from the class of cement employed rather than from the color applied afterward.

Working Conditions at Porcupine

Wagon-roads around Porenpine are good in the winter, but nearly impassable in summer. Freight rates to the outlying mines range from \$2.50 to \$3 per ton in winter and \$10 to \$15 in the spring. Telephones connect outlying properties with the town and with each other. Wood, where used for fuel, must be cut in winter and hauled to the power-houses. Supplies should be brought in during the winter. Since the completion of the railroad, prices run about the same as in the other mining districts of Ontario. General labor is plentiful, though experienced miners are scarce. The wage is \$4 per 9-hour shift for carpenters, \$3.85 for machine-men, \$3.10 for trammers, \$3 for topmen, and \$2.85 for firemen and general surface labor.

Miami Copper Company

By B. BRITTON GOTTSBERGER

*The past year witnessed the end of the preparatory period of the operations and entrance of the company into the producing class. On March 15, 1911, one section of the mill was started, and from that date production continued on an increasing scale to the end of the year, when five sections were running, treating about 2500 tons of ore per day. The equipment of the sixth section is complete with the exception of the fine-grinding machinery. These machines will be in place by the middle of this month, and the entire plant operating with a daily capacity of 3000 tons.

Mine.—The mine has responded without difficulty to the increasing demand for ore. The output of 2000 tons per day, originally planned, has already been exceeded and development is under way to place the mine on a 3000-ton basis. This has progressed far enough to insure the mill supply by making up any deficiency from the stock pile.

POWER-HOUSE AT MIAMI.

The underground work consisted mainly of completing the 420-ft. tramming level and opening the ground in the northwest portion of the orebody, the limits of which had been defined by churn-drilling. On the 570-ft. level, designed to be the second tramming level, the drift from No. 4 shaft was advanced to the orebody, and during the coming year this level will be opened, preparatory to starting work on the sub-levels between the 420 and 570-ft. levels. During the year 32,935 ft. of drifts and raises were driven.

The ore extracted by stoping was taken largely from the eastern part of the mine, above the 370-ft. level. This work was started by cutting out under the capping by means of square sets and has progressed by a combination of square-setting and sub-level caving which has been very satisfactory. The capping above this ore has caved, the result showing on the surface, where a gradual subsidence of the ground is taking place. This result was anticipated and is causing no serious inconvenience. In the west and northwest parts of the mine it is planned to extract the ore by means of shrinkage stope rooms. Five of these rooms have been started and their working has been most satisfactory. The ore hoisted during the year amounted to 450,036 tons, derived from the following sources:

	Tons.
Stock pile	43,347
Mine development	152,074
Square set and sub-level caving	204,362
Shrinkage stope rooms	50,163
Total	450,036

Previous to the starting of the mill, 18,771 tons of ore was added to the stock pile, and at the end of the year the amount remaining was 226,343 tons in the stock pile and 5000 tons in the bins.

Mill.—As stated above, milling of ore was started in the month of March, and the plant has operated continuously

*From report as general manager, for the year ended December 31, 1911.

since that time, handling a gradually increased tonnage. The estimated capacity of 2000 tons per day for the entire plant has been greatly exceeded, the amount treated per section having been increased to about 500 tons per day. The operation of the plant from a meechanical and a metallurgical standpoint has been very gratifying. The results of milling operations for the year are as follows:

Ore milled, tons (2.48% copper).....	445,036
Concentrate produced, tons (40.36% copper).....	20,065
Copper in concentrate, pounds.....	16,195,561
Copper recovered per ton, pounds.....	36.39
Mill extraction, per cent.....	73.37

Production.—From the concentrate produced the net re-

inal design of the plant, so that no increase in the size of the building was required. At the main water-supply pumping plant the second pump has been equipped with an electric motor, so that this plant is now complete in duplicate, thus insuring against any possible failure in the water-supply. At this plant a small air-compressor has been installed and used for testing the driven wells on the ranch. One of these has been flowing at the rate of 250 gallons per minute for some time. It is the intention to pipe these wells to the pump and make use of this supply of water. From this source it is expected that from 500,000 to 1,000,000 gallons of water per day will be ob-

MAIN HOISTING SHAFT AND ORE-BINS, MIAMI COPPER COMPANY.

turn of refined copper amounted to 15,385,783 lb. Based on the net production, the cost of copper in concentrate on board cars at Miami was as follows:

	Per Ton Ore.	Per Lb. Copper.
Mining	\$1.2134	\$0.03500
Milling	0.6274	0.01810
General	0.1706	0.00492
Total	\$2.0114	\$0.05802

Ore Reserves.—Prospecting the unexplored territory adjacent to the orebody by means of churn-drills in progress during the early part of the year was discontinued. The drilling done consisted of eight new holes, most of which were in ground too low in grade to be considered of value. Hole No. 37, drilled in the bottom of No. 3 shaft situated on the Red Spring mining claim, disclosed ore of commercial grade, and drilling has just been resumed to complete the examination of this part of the company's ground. Underground, the development drifts and raises have confirmed the churn-drill work in the northwest part of the orebody and above the 420-ft. level have added slightly to the ore developed. After allowing for the ore extracted during the year, the reserves are estimated to amount to 18,232,000 tons, averaging 2.58% copper.

Construction.—The equipment of the milling plant is, as before stated, practically complete, and the entire plant will be in operation in the near future. To provide the power necessary to handle the increased tonnage of ore, additional machinery is now being installed at the power-plant and will soon be in operation. These facilities consist of a third 1000-kw. electric generator, a second air-compressor of 4000 cu. ft. capacity, and a spare condenser. Foundations for these machines were provided in the orig-

inaired in addition to the 2,000,000 gal. per day now being received from the Old Dominion mine.

Additional details are given in the tables below:

ORE PRODUCTION

	Tons.	Per Ton.	Total.
Inventory stock pile.....	269,780	\$1.0000	\$269,780.00
Mine development	450,036	0.3100	139,511.16

The Osaruzawa Mine

By TAKESHI KAWAMURA

The Mitsu Bishi Company is one of the largest private concerns in Japan, and has among its holdings ten metal mines, including the Osaruzawa, Arakawa, and Hisaichi in kilograms; copper, 6000 long tons; coal, 2,000,000 long tons. This production is annually increasing.

The Osaruzawa mine, one of the more important prop-

FLOW-SHEET OF THE OSARUZAWA MILL.

Akita prefecture; Takara in Yamanashi; Sado in Niigata; Omodani in Fukui; Ikuno in Hyogo; Yoshioka in Okayama; Makimine in Miyazaki; Togi in Ishikawa. The company also owns eight coal mines, including the Namazuta, Kamiyamada, Shinnew, Hojo, and Kanada, in Fukuoka prefecture; Ochi, Mutabe, and Yoshinotani in Saga; and the Takashima in Nagasaki. The company is one of the principal mining firms in Japan, and its total output (average taken for the past five years ended 1910) amounts roundly to the following figures: gold, 700 kilograms; silver, 16,000

erties of the company, is also one of the principal copper mines of Japan. It ranks only behind Ashio, Kosaka, Besshi, and Hitachi mines. It is situated near the town of Hamawa, Kazuno district, Akita prefecture, and can be reached by a five hours' journey from Odate on the O-U railway line. The journey is first over the Kosaka railway leading to that well known property of the Fujita & Co., followed by a 15-mile riksha ride over a fair road. Freight to and from the mine goes by another road direct from the mine with Odate. The concession on which the

mine is situated measures 1427 acres. Tradition dates the discovery of the mine as far back as the early part of the eighth century, since which time gold-mining was intermittently carried on until the feudal lord of the district made it his property some 150 years ago. The auriferous veins discovered having been nearly worked out at the time, efforts were turned chiefly to the winning of copper. The property went through many vicissitudes, but the average output of copper per year during the ownership of the fief seems to have been not less than 365 tons. After passing into the possession of a private merchant at the beginning of the reign of the present Mikado, the mine changed hands several times until in 1887 it became the property of the Iwasaki family, from which it was taken over, in 1893, by the Mitsu Bishi company, which is controlled by the Iwasaki families.

The ore deposit occurs in the form of veins filling numberless fissures in the country rocks which consist of Tertiary shale and tuff and volcanic rocks. The latter include liparite and propylite. The veins constitute a most complicated series intersecting at many points, and range in width from less than 1 to over 20 ft. The strike of the different veins varies, but according to dip they may be classified into five groups of 15, 45, 75, 105, and 135°, respectively. For convenience of operation they are, however, divided into three main workings, the Motoyama, the Takori, and the Akazawa mines. The ores consist of chalcopyrite, bornite, chalcocite, and native copper, of which the first named constitutes the greater part. Carrying a high percentage of iron pyrite and frequently associated with blende, galena, and hematite, they are rather poor in quality, 3 to 4% being the usual quantity of copper contained.

In mining, overhand stoping has been adopted. In driving levels when haste is necessary, rock-drills are sometimes employed. For this purpose three water Leyner 2½-in. drills are used. Air is furnished by a 12 by 4-in. tandem two-stage compressor made by the Leyner company, and driven by a 50-hp. induction motor. The mine is opened by ten adit-levels, and there is only one blind shaft. This is the Motoyama mine and is of 6 ft. 6 in. by 14 ft. 3 in. cross-section, and 347 ft. deep. The ore is hoisted by a Lidgerwood double-drum friction hoist, driven by a 35-hp. induction motor. Two more shafts will soon be opened, one in the Motoyama and the other in the Akazawa mine.

An unfavorable feature of the mining here is that, owing to the scarcity of timber and small rainfall in the district, water, especially for ore-dressing purposes, is scarce. To remedy this condition a powerful pumping station is being built on the Yoneshiro river. In it will be placed two 150-hp. 10 by 15-in., 3-throw horizontal plunger pumps. Water will be sent by them about 10,000 ft. to the mine. On the completion of this station, the ore-dressing and other plants will be greatly extended.

After underground sorting, ore richer than 12% copper is classed as first and sent directly to the smelter. Ore containing less copper is classified into middle and third class, containing about 8 and 3% copper, respectively, and are taken to the concentrating mill, which stands on the Shinko adit of the Motoyama mine. The middle-class ore is subjected to spalling and cobbing, and its middling is treated like the third-class ores. The outline of the present Osaruzawa concentrator is shown in the accompanying flow-sheet. At this mine were installed the first Hancock jig, Akron (Chilean mill, Richards pulsator classifier, Sperry slimers, Callow cones, and Fremier sand-pumps used in Japan. The concentration ratio is 3:1, while the recovery of metals averages 70 per cent.

The concentrate contains about 80% of material smaller than 12 mm. Formerly this fine material was roasted in 8 roasting furnaces of Herreshoff type. The roasted material was mixed, with slime produced in the concentration, by mixing machines moved by a 10-hp. motor and then made into briquettes by 52 steel stamps weighing 82½ lb. each. The briquettes were dried in 16 drying furnaces with the waste heat of molten slag. Since the roasting pot proved to be satisfactory, 7 cast-steel pots, each of 8 ft.

1 in. diameter and 5 ft. deep, have been used. Each has a capacity of 8 long tons. To furnish blast there are two Root No. 4 blowers, driven by a 50-hp. induction motor. A single campaign of the roaster occupies 8 hours. The feed contains 22% sulphur, while that in the product contains but 4 to 5%. The roasted product equals 80 to 90% by weight of original charge, while the fine material that must be returned to the next campaign constitutes 20% of the roasted product.

The ore larger than 12 mm. is fed into the furnaces raw. There are 3 blast-furnaces: No. 1, 180 by 42 in.; No. 2, 96 by 36 in.; No. 3, round, 45 in. diameter at the tuyeres. The No. 2 furnace is commonly used while the others are held in reserve. One charge consists of one long ton of ore containing 7% Cu, 200 kg. of refinery slag, and 300 kg. of limestone. The capacity of the furnace is 90 to 100 tons of ore with the pressure of 45 mm. The matte, of 45% Cu, is intermittently tapped from the forehearth into cast-steel pots and carried to the refinery in a molten state. The average composition of slag is: SiO₂, 40%; Fe₂O₃, 32%; CaO, 15%; Al₂O₃, 5.6%; MgO, 2.7%; and CuO, 0.25%. Blast is furnished by three Thwaites No. 7 Root blowers, two being driven by a 100-hp. motor, while the other is held in reserve.

For refining, there are ten *mabuki* hearths. These are constructed of charcoal powder and clay, in the ground, being 3 ft. in diameter and 1.8 ft. deep. The *mabuki* is a primitive process of bessemerizing and has been in practical use in Japan for a long time. Though it is simple and depends solely upon the laborer's skill, it permits good results to be obtained at very low initial cost. It is, therefore, in use at all the copper mines of Japan except the four larger ones previously mentioned. Four to five long tons of 45% matte is charged in the hearth molten and blown for 23 to 24 hours, at 40-mm. pressure, into blister copper of 98% purity. The blister copper contains 0.0008% gold and 0.06% silver. It is shipped to the Osaka electric refinery belonging to the Mitsu Bishi Company, where the noble metals are recovered.

For the supply of the power, the mine has a hydraulic power-house with a 150 and a 200-kw. generator at a point about seven miles distant. A second power-house has lately been erected, with one of the three 500-kw. generators that are to be used in it. Altogether, 1600 hands are employed at the time; the monthly output of ores averages 8000 tons, while the smelting works turns out copper to a monthly amount of 180 long tons. The production of the mine for 1910 is as follows: gold, 13,005 kg.; silver, 1192.728 kg.; copper, 2295.607 long tons.

Softening Water by Permutite

Permutite is an artificial zeolite which has the property of removing certain constituents from water and of softening it, as described by A. Kolb in the *Chemische Zeitung*. The constitution of the substance is

Experiments were made, both by shaking and filtration, as to the interchange taking place between permutite and chlorides of calcium, magnesium, and potassium, and it was found that the soda of the permutite was replaced by the bases of the salts added in molecular proportions. The permutite could be regenerated by treating the used substance with common salt. As well as the alkaline earth metals, iron and manganese could be removed similarly from solution. It is stated that with a filter formed of permutite complete softening of water can be effected. The water must not be acid, and must not contain suspended matter. A muddy water, in addition to blocking the pores of the filter, coats the grains of the filtering material with inert matter and prevents the chemical reaction taking place. The regeneration of permutite by a solution of common salt is of industrial importance, as it enables the same filter to be used for an indefinite time. The richness of the treated water in sodium salts is not detrimental to a boiler-feed water.

Work of the Tonopah Mining Company

In the tenth annual report of the Tonopah Mining Co., recently issued, there is much of technical interest. W. H. Blackburn, superintendent of the mine, gives the average mining costs for the year as below:

Per ton of dry ore shipped to mill.....	\$3.704
Including diamond-drilling and extra excavation.....	3.740
Per ton of wet ore and waste hoisted.....	2.960

The apparent reduction of 25c. per ton below the cost of the preceding year is stated to be due principally to curtailment of development work and cessation of pumping from the lower levels of the Mizpah shaft. No new ore-bodies have been found, though the boundaries of known orebodies have been extended. The estimated value of the ore reserve February 1, 1912, was \$5,237,974. The total available tonnage at that date, including ore in dumps, was 304,824. The average cost per ton of mining, milling, and marketing the ore for the past year, excluding extraordinary work, was as below:

Mining	\$3.71
Milling	2.74
Metal losses in milling.....	1.89
Freight on ore milled.....	0.72
Marketing mill products.....	0.57
Total	\$9.63
Profit per ton	\$10.34

As is well known, the company has been making active efforts to find a new mine, and as to that J. E. Spurr makes the following comment:

"The search for new mines, to enlarge the sphere of operations of the company, has been systematically carried on. Our work has consisted both in sending our own engineers into favorable districts to investigate, and in considering properties brought to us by outside engineers and others interested in mining. The total number of properties thus submitted is very large, averaging around 50 per month thus far. Of these, many are eliminated after careful study of the reports and maps which are presented, and are declined either as of no value or not suitable to the company's purposes. Certain kinds of mines are eliminated because they are outside of the class in which the Tonopah Mining Co. feels that by experience and equipment it can rank as a specialist. Many of the properties brought in are rejected at once on account of small size of orebodies, too high price, too stringent terms of sale, or difficult conditions of operation. Those which appear attractive are selected and made the basis for further negotiations and inquiry, and if this is satisfactory, options are secured giving opportunity for careful examination, measurement of ore, and appraisal of future probabilities. A preliminary report is made by one of the staff of engineers; if this is favorable, the property is examined briefly by myself and a decision is made as to an exhaustive examination. During the last three months some 25 properties, roughly speaking, have been examined in the field, of which about 10 were inspected by the writer. Two of the properties examined are being considered favorably at present, and these are being carefully examined by our staff engineers. There are several other attractive properties that are about to be investigated."

A. R. Parsons, mill superintendent, states that there was so little departure from the regular routine, in the operations of the milling plant of the Desert Power & Mill Co., during the last fiscal year, that a review of such operations is necessarily brief.

In the last year's report, attention was called to the condition of the Huntington mills, and under an appropriation of \$11,660.86 two Chilean mills were installed, replacing the five Huntingtons used for regrinding the oversize from the stamp batteries. Three of the old Huntington mills were left in place, being put in service while making repairs to either of the Chileans. The cost of regrinding in Huntington mills during the year 1910-1911 amounted to

\$0.169 per ton of ore milled; the cost of regrinding in Chilean mills since July 1, 1911, to February 29, 1912, was \$0.117 per ton of ore milled, a reduction in the regrinding cost amounting to \$0.052 per ton of ore milled. Since September 1911 the mill has been operated without the Johnson vanners, formerly used for concentrating the finer ore, as experiments indicated that the mineral could be recovered by cyanidation, making a saving to the company through a reduction in the cost of marketing concentrate, of which the Johnson vanners produced about one-third.

During the year there were milled and treated 174,685 dry tons of ore, averaging 0.286 oz. gold and 26.05 oz. silver, or \$19.97 per ton, which is 0.034 oz. gold and 2.60 oz. silver, or \$2.01 per ton, lower than the average of the ore milled during the previous year, when silver averaged \$0.424 per oz. lower. The total contents of the ore milled were 49,796 oz. gold and 4,550,199 oz. of silver, with a gross value of \$3,503,255.21, from which there was recovered by concentration and shipped to the smelter 1290 dry tons of concentrate averaging 4.962 oz. of gold and 696.66 oz. of silver per ton, with a total content of 6400.101 oz. gold and 898,509.82 oz. silver, and a smelter gross value of \$589,349.56. The cyanide treatment yielded in bullion 3,379,712.66 troy ounces, containing 38,493.312 fine ounces of gold and 3,217,601.61 fine ounces of silver, with a smelter gross value of \$2,545,557. The slag and refinery by-products shipped to smelter amounted to 86 dry tons, averaging 0.832 oz. gold and 54.72 oz. silver per ton, with a total content of 71.741 oz. gold and 4720.18 oz. silver, of a gross value of \$3849. The cost of marketing products, including freight, treatment, sampling, and express on bullion, concentrate, and slag, amounted to \$81,203, or 46.5c. per ton of ore milled, a decrease of 5.1c. per ton compared with the cost of the previous year. This is due to a lower value of the concentrate, the smaller quantity of products produced, and a recent cut of \$1.50 per \$1000 valuation in the express rate on bullion. During 1911-1912 silver averaged 54.079c. per oz., an increase of 0.424c. per oz. over the price of the previous year. This increase in price applied to the 4,120,832 oz. silver produced, added \$17,472 to the revenue derived from silver produced above what would have been realized on the quotations of the year previous.

The percentage of recovery by concentration, cyanidation, and combined extraction shows the recovery by concentration to have been 12.75% of the gold and 19.75% of the silver content of the ore. The recovery by cyanidation was 77.5% of the gold and 70.81% of the silver content of the ore; giving a combined extraction by concentration and cyanidation of 90.25% of the gold and 90.56 of the silver, total 90.56 of the content of the ore. The combined recovery for the previous year was 90.13% of the gold and 92.40 of the silver, total gold and silver recovery 92.40% of the ore contents. Upon comparison, this shows an increase of 0.12% in the gold extraction and a decrease of 1.84 in the silver extraction. In reality, there was an improvement in extraction, both of gold and silver; the contradiction of this statement by the figures above being explained by the manner in which the contents of the ore milled were calculated. Had the gold and silver in the products of last year been added to the gold and silver in the residue discharged from the plant and these results been taken as the gold and silver contents of the ore milled, as was done this year, the extraction for the year 1910-1911 would have been 90% of gold and 90.01 of silver.

The milling costs for the year 1911-1912 were \$0.208 per ton lower than during 1910-1911. The direct milling cost per ton for 1910-1911 was \$2.732, indirect \$0.212, total \$2.944. The direct milling cost per ton for 1911-1912 was \$2.532, indirect \$0.204, total \$2.736. A decrease in the direct cost amounting to \$0.20 per ton, indirect \$0.008, total, \$0.208 per ton, as above. A further analysis of the cost sheets shows that the reduction of \$0.200 per ton in the direct costs is made up of a reduction of \$0.0716 per ton for labor, \$0.1376 per ton for supplies, total \$0.2092, and an increase of \$0.0092 per ton for power, leaving the net reduction \$0.200 per ton.

C. A. Higbee, secretary of the company, lists the dividends paid as below:

No.	Date paid.	Rate, %	Amount.
1	April 22, 1905	25	\$250,000
2	July 22, 1905	25	250,000
3	Oct. 21, 1905	25	250,000
4	Jan. 22, 1906	25	250,000
5	April 21, 1906	25	250,000
6	July 21, 1906	35	350,000
7	Oct. 20, 1906	35	350,000
8	Jan. 21, 1907	35	350,000
9	April 22, 1907	35	350,000
10	July 22, 1907	25	250,000
11	Oct. 21, 1907	25	250,000
12	July 21, 1908	25	250,000
13	Oct. 21, 1908	25	250,000
14	Jan. 21, 1909	25	250,000
15	April 21, 1909	35	350,000
16	July 21, 1909	35	350,000
17	Oct. 21, 1909	35	350,000
18	Jan. 21, 1910	35	350,000
19	April 21, 1910	35	350,000
20	July 21, 1910	40	400,000
21	Oct. 21, 1910	40	400,000
22	Jan. 21, 1911	40	400,000
23	April 21, 1911	40	400,000
24	July 21, 1911	40	400,000
25	Oct. 21, 1911	40	400,000
26	Jan. 20, 1912	40	400,000
*27	April 20, 1912	40	400,000
			\$8,850,000

*Declared March 14, 1912.

In addition to the dividends above, in February 1905 the company retired its issued and outstanding preferred stock, with interest, amounting to a total of \$380,557.

The balance sheet of the company shows its assets to be as below:

Property	\$1,410,040.22
*Exhaustion of ore deposits, to date	859,817.42
	550,222.80
Plant and betterments	59,573.81
Total property, plant and betterments	\$609,796.61
Stocks and bonds owned	3,151,578.50
Total investments	\$3,151,578.50
Loans and advances to subsidiary companies	56,037.71
Accounts receivable:	
Miscellaneous	17,129.93
Desert Power & Mill Co.	89,890.38
Materials and supplies	39,765.61
Net value of ore on dump	248,349.33
Stored ore at mill at cost of mining and handling	39,931.27
Loans on collateral	50,000.00
Certificates of deposit	325,000.00
Cash	479,043.78
Total current accounts	\$1,345,148.01
Deferred charges (unexpired insurance)	1,527.18
Total assets	\$5,108,050.30

*This exhaustion of ore deposits at \$1.54 per ton, from the period January 1, 1909, to February 29, 1912, is placed upon the books of the company in accordance with the rules, regulations, and instructions of the U. S. Internal Revenue Service.

It is interesting to note that the surplus of the company is invested in large part, though not wholly, in local securities. The complete list is as below:

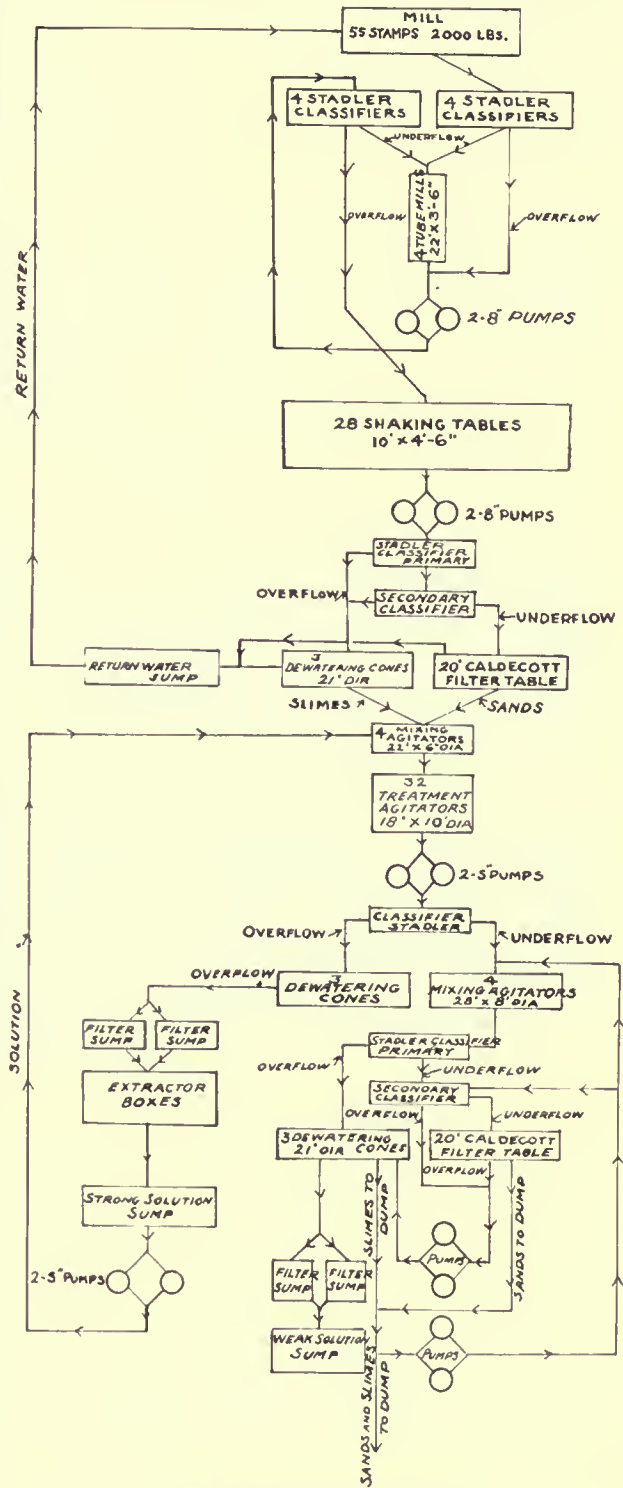

Tonopah & Goldfield Railroad Co. common stock	\$988,700.00
Tonopah & Goldfield Railroad Co. preferred stock	283,400.00
Desert Power & Mill Co. mill	800,000.00
Esmeralda Power Co. stock	127,200.00
Tonopah & Crystal Water Co. stock	3,241.00
Tonopah Banking Corporation stock	1,400.00
(Par. val. bonds.)	
Reading Co. gen. mtg. 4% bonds	\$350,000 342,375.00
Southern Pacific Co. San Francisco Terminal first mtg. 4% bonds	225,000 208,700.00
Public Service Corporation of New Jersey gen. mtg. 5% bonds	100,000 93,750.00
Kansas City, Ft. Scott & Memphis R. R. Co. refunding 4% bonds	100,000 79,750.00
Manufacturers Water Co. 5% notes	75,000 75,000.00
Great Northern Ry. and Northern Pacific Ry. joint (C. B. & Q.) 4% bonds	50,000 48,000.00
Jamestown, Franklin & Clearfield R. R. Co. first mtg. 4% bonds	50,000 47,062.50
Pacific Power Co. first mtg. 6% bonds	40,000 39,000.00
Midway Milling Co. first mtg. 6% bonds	35,000 13,000.00
Loans on collateral	50,000.00
Loans to subsidiary companies	58,918.39
Certificates of deposit	325,000.00
Selby Smelting & Lead Co. mill products	219,695.29
Cash	886,266.65
Absorption in Desert mill	53,860.00
Storehouse supplies	126,142.43
Ore on dump at Tonopah	248,349.33
Ore at Desert mill	48,197.36
Accrued interest on loans and bonds	14,249.25
Prepaid insurance	6,930.50
Accounts collectable, miscellaneous	1,682.89
Total Invested	\$5,189,870.59

From this amount there are deductions for accrued taxes, accounts payable, insurance, net exhaustion of ore, amounting to \$509,828.48. The whole report indicates that, whatever may be the success of the company in reinvesting its surplus and operating a new mine, it has done excellently with the Mizpah.

The Way-Arbuckle Process at Benoni

JOHANNESBURG CORRESPONDENCE

During the past twelve months some interest has been aroused by the announcement that, although the East Rand Proprietary Mines decided against the adoption of the Arbuckle process, the Benoni Consolidated Mines, on

FLOW-SHEET, BENONI MILL.

the recommendation of the consulting engineer, has decided to adopt it, subject to certain modifications, at the Benoni mines. In its altered form it is called the Way-Arbuckle process and possesses several new features. The most interesting of these is the proposed continuous treatment of the sand and slime by using the Arbuckle dewatering and thickening cones in conjunction with the Way-Arbuckle agitators and the extensive use to be made of

the Stadler classifier. There is nothing novel in the stamp-mill, which consists of 55 stamps, 2000 lb. each, and is designed according to the results of the experiments made from time to time by the Mines Trials Committee of the Chamber of Mines, so as to obtain the highest efficiency with stamps and tube-mills.

The real objects are to obtain a maximum crushing efficiency and to simplify the treatment of sand and slime, and to reduce the time necessary for their handling to a minimum. But the simplification of the treatment of the combined sand and slime at one continuous operation and in as many hours as the ordinary system takes days, has attracted the most attention, and it is just this part of the process that seems, so far, to have failed. Had it succeeded as anticipated by Mr. Way, it would not only have saved time and expense, but would probably have at the same time materially reduced the capital cost of Rand reduction plants. But, like the Giesecke mill, it seems to have proved a failure as yet, though a short detailed description of the process, together with a flow-sheet of the plant, may not be without interest.

Referring to the flow-sheet, it will be noticed that the mill-pulp is classified by four Stadler classifiers, the overflow joining the discharge from the tube-mills, and is raised by pumps to other classifiers, where the separation of the +60-mesh can take place without overloading the tube-mills with -60-mesh material. The underflow from these classifiers is returned to the tube-mills, and the overflow to the 28 shaking-tables.

After passing over these shaking-tables the pulp is again pumped to Stadler classifiers, the overflow going to three Arbuckle dewatering cones, and the overflow to a 20-ft. Caldecott filter-table. From the dewatering cones and Caldecott table the water passes to the return sump; the slime from the cones as well as the sand from the table going to the first set of agitators to be mixed with strong solution before reaching the Way-Arbuckle agitators. Here the pulp is aerated for four or five hours, during which time the gold should be practically dissolved. It is again elevated to a Stadler classifier, the overflow passing to the Arbuckle thickening-cones, and the underflow to the second set of agitators, where with the underflow from the classifier it is mixed with weak cyanide solution. The overflow from the cones is run to the zinc-boxes, the overflow being pumped to the first set of four mixing agitators. The pulp under agitation with the cyanide solution passes from the second set of agitators to two sets of Stadler classifiers, the underflow being run to a 20-ft. Caldecott filter-table. The overflow goes to the second set of thickening-cones. The residue when taken from the Caldecott table is quite dry and passes direct to a belt, while the slime pulp, after being dewatered, is conveyed to the dump by the residue-sand belt.

The reduction plant was started near the end of last year, and it was soon known that trouble was being experienced with the handling of the slime. However, at the end of November it was officially announced that the mill was crushing at the rate of 500 tons per day, and that the mill and sand plant were running smoothly. As regards the slime plant, the consulting engineer assures the board that it will be a proved success as soon as a few initial mechanical difficulties are overcome. The slime meanwhile is being temporarily stored, and the consulting engineer of the company is thoroughly satisfied with the ultimate efficiency and economy of the whole of the reduction plant.

The first declaration of output as the result of running the reduction plant was made last January, when 17,000 tons had been milled with a yield averaging 18s. 4d. per ton at a cost of 21s. 2d. per ton for mining and milling, showing a loss of practically 3s. per ton, while during February 19,000 tons was treated which, with a yield of 19s. 7d. per ton, just managed to pay expenses. The slime meanwhile is being stored.

The manager reports as follows to the end of December: "The preliminary running of the reduction plant has proved satisfactory so far as the crushing and sorting station, the

mill and tube-mills, and the waste-rock conveyors are concerned. In the cyanide plant it was found that the elevation of the settled slime by means of the screws attached to the Arbuckle settling-cones was not feasible, and centrifugal pumps were installed beneath each set of cones. The thickened slime is now drawn off from the underside of the cones and pumped direct to the treatment agitators. The same operation is performed after treatment and the residue delivered to a slime-dam. It appears, however, that with this latter method of dealing with the settling capacity of slime, the nine Arbuckle cones are insufficient for the slime product from a mill feed of 20,000 tons per month. The absorption of gold which invariably takes place in a new plant accounts for the low actual extraction from November 12 to December 31, and will affect the extraction also to a less extent during the month of January." With this description of the results of the first run of this plant, the consulting engineer, Mr. Way, expressed his entire agreement, pointing out that certain additions to the cyanide plant will be necessary to bring it up to the capacity for which it was intended, and he was of the opinion that when these additions were made the company will have a plant capable of giving a high extraction which will be mechanically efficient at a satisfactory working cost.

The Jumpers Gold Mining Co., Ltd., which holds a large interest in the Benoni Consolidated Mines, considered it advisable to call in an independent engineer to report on the whole position, and W. Laurie Hamilton was engaged. In his report he has no fault to find with the sorting and crushing plant, but definitely states that the Way-Arbuckle plant as erected at this mine has not proved a success. He does not condemn the process, as it seems that with certain modification and additions it may be made a success. The Caldecott tables do good work, but the Arbuckle slime dewatering and thickening cones failed to do the work for which they were intended, and with these cones Mr. Hamilton does not recommend further experiment. The main principle of the process was to re-mix the sand and slime after dewatering, and re-treat the mixtures in the 32 agitators, but owing to the failure of the screw cones, the treatment of the slime had to be abandoned. This militated against the complete success of the agitators, as the presence of the slime would help materially in the agitation. Yet in spite of this drawback, so long as the treatment was continuous and without unexpected stoppages, it was fairly successful. There was no proper arrangement for drawing off the contents of any individual tank when for any reason it became necessary to cut it out of the circuit, and in the event of any unforeseen stoppage of the circuit, all the agitators at once silt up. Recently a failure at the transformer house cut off the power for 3½ hours, with the result that the agitators became silted up to such an extent that it took 12 hours to get them running again. Another stoppage of 2½ minutes of the air-compressor caused 2 hours stoppage, and these stoppages affect everything back to and including the mill. An arrangement to obviate this is absolutely necessary, including the substitution of some other arrangement for the dewatering cones, and then perhaps the plant may be fairly successful in treating both sand and slime. F. L. Bosqui is also reporting on the plant.

TRANSVAAL gold output for the month of March has been declared at 830,723 fine oz., valued at £3,528,688. Included in this total, which is the highest yet recorded, was reserve gold amounting to 70,143 fine oz., valued at £297,946.

THE COPPER RANGE CONSOLIDATED COMPANY OF HOUGHTON, is about to add to the traction equipment of its mines five 4-ton electric trolley mining-locomotives, purchased from the General Electric Company.

THE Elmore vacuum plant at the mines of the Sulitjelma company, Norway, produced 884 tons of copper concentrate during the month of April.

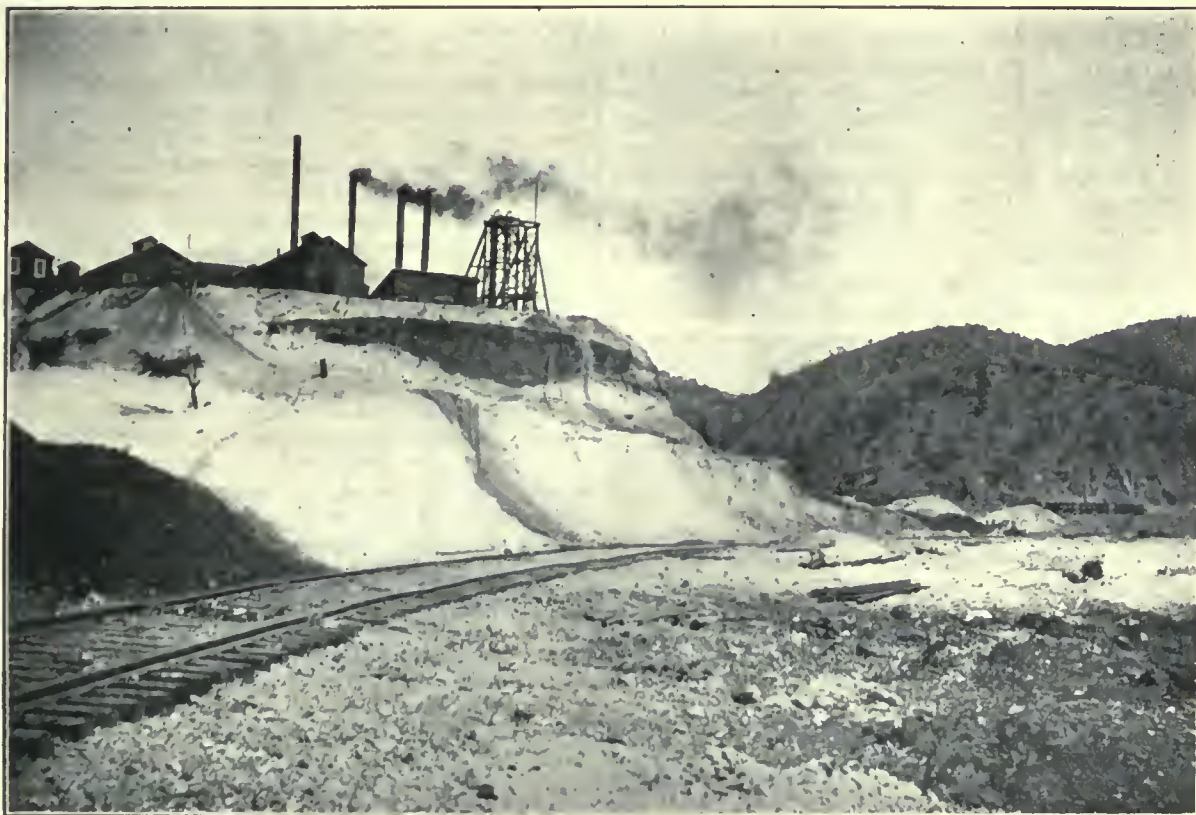

Work of the Chino Copper Company

By D. C. JACKLING

***Mining Property.**—Since the last report a number of additional mining claims have been patented and some changes have been made on other accounts in the unpatented list of claims. A number of locations lying outside of the mineral zone, and therefore having no value except for surface purposes, were found to be superfluous and were abandoned. A few additional locations and purchases have been made, with the result that the total number of claims now owned and controlled, either by patent or location, is 144. Of this number, final patent has been received for 95. Final receipts from the Land Office have been issued, covering 36 others, leaving only 13 claims upon which it is

and the titles or other evidences of ownership and control are in a satisfactory state throughout.

Development and Improvements at the Mine.—On the date of the last annual report, 208 drill-holes, together with underground work, had developed a total of a little less than 19,000,000 tons of ore. After that date only a comparatively small amount of underground work was done for development purposes, as it soon became apparent that a much greater percentage of these ore deposits could be mined by steam-shovel than was at that time thought possible, and it will be unnecessary to do any considerable amount of underground mining for a great many years.

ROMERO OPEN-CUT AND THE OLD MINE WORKINGS, CHINO.

necessary under government regulations to do further work before patent can be procured. The total acreage of all claims, patented and unpatented, is 2643, of which 2412 are covered by patent and receiver's certificate, leaving 231 acres, covering which application for patent has not been made. The company also owns at Santa Rita, New Mexico, 160 acres of patented lands acquired under agricultural entry, making the total area of all classes of claims and lands owned at Santa Rita 2803 acres. This, together with some small areas and rights of way in connection with which surface rights only have been purchased, rounds out the property into a solid block of ground containing everything in the vicinity that is at all likely to be of value or needed either for mining or surface uses.

Millsite and Water Right Property.—The total area owned and controlled at Hurley and in that vicinity for millsite purposes and in connection with water rights is 7156 acres. Of this total, 677 acres is leased from the state and individuals, the area owned by the company being therefore 6479 acres. This comprises all the lands that are now or are likely at any time in the future to be required,

Development by drilling was continued until about October 1, 1911, at which time 467 holes, aggregating a total of 182,000 ft. of drilling, had been completed. Of this number, 409 holes showed ore of commercial value. The average depth of the holes proving the existence of orebodies was 385 ft., and the average thickness of the ore so disclosed is 107 ft. Drilling of the area in which these holes were situated was completed in such a way that all of the ore is now properly classed as fully developed. The principle of drilling regularly on the corners of 200-ft. squares was followed, except where there was any irregularity of the ore occurrence or uncertainty as to value, and in such cases the ground was drilled at more frequent intervals wherever necessary to fully demonstrate the facts.

The total ore so developed is 54,970,646 tons, containing an average of 2.24% copper. Of this quantity, it is estimated that something over 32,000,000 tons, or nearly 60%, can be mined by steam-shovel. The average grade of ores that will be mined in this way is slightly less than the average grade of all ores developed, being 2.21% copper. Calculations as to the percentage of ore that may be more economically mined by steam-shovel than by underground methods are based on mining by this means to a depth of not exceeding 200 ft. below the average

*From annual report as general manager for the period ended December 31, 1911.

surface. In certain portions of the ore deposits it will be desirable and practicable to extend steam-shovel or open-pit mining to considerably greater depths, and therefore the percentage of ores that will actually be mined in this way will be considerably greater than that stated.

Further developments will unquestionably result in the disclosure of large additional tonnages, particularly in a southwesterly extension on the south side of Santa Rita creek, where sufficient drilling was done before development operations ceased to indicate extensive orebodies of good commercial grade. These bodies will not, however, connect directly with the main orebody now developed, and will probably be mined entirely by underground methods, and consequently the plans for mining them and methods of developing for that purpose will not be affected in any way by the extraction of the orebodies on which we are now working, and as we have already proved a quantity of ore sufficient to supply to its full capacity the mill we are now completing, for approximately thirty years, it was not deemed necessary at this time to continue the development of further reserves.

The mine has been provided with commodious shops, warehouses, etc., as well as living quarters for officers and employees, and no further construction or facilities of these kinds will be necessary. Electric power for all mining and domestic purposes is being supplied from the central steam-plant at Hurley. Resultant upon the decision to increase the mill capacity from 3000 to 5000 tons per day, it was necessary to increase the steam-shovel and locomotive equipment. The company now has 6 steam-shovels and 9 locomotives in use, and 2 additional locomotives have been ordered. Permanent trackage arrangements and yards connecting with the Santa Fé railroad have been completed. The total trackage owned by the company in these yards and about the mine on January 1 was about 10.5 miles, and it is estimated that the completion of the entire system will require some eight miles of additional tracks.

Operations at the Mine.—The total quantity of material moved by steam-shovels up to the end of 1911 was nearly 2,000,000 yards. Of this quantity 1,700,000 yd. was waste, the remainder being ore of a more or less oxidized character. The latter was put in stock-piles for future use, except as to a comparatively small tonnage sent to the mill. The average cost of steam-shoveling for the period was 31.68c. per yard, being equivalent to a little over 15c. per ton. At the present time the quantity of stripping and ore being handled amounts to about 250,000 cu. yd. per month, the cost being about 26c. per cu. yd., and it is believed that the average cost applying in the future will not exceed this figure.

All of the ores mined and sent to the mill have come from near the surface of the Romero, Whim Hill, and Chino sections—most of it from the Romero, the largest pit now opened. The upper ore zones that have been and are now available for mining in these three sections, and especially the Romero, contain considerable quantities of oxidized material which it is necessary to send to the mill or to the ore stock-piles in order to avoid wasting about equal amounts of good concentrating ore associated with it. The result of this situation is that the ore which has been going to the concentrator contains approximately one-half its copper content in the form of carbonates, which are not recoverable in large percentage by concentration. This condition will prevail for several months with respect to the orebodies in question, or until the first steam-shovel cut, representing about 40 ft. in thickness of these mixed ores, can be removed. In the meantime, the character of the ore is gradually improving in the sections from which we are now producing, and it is expected that, by the middle of the current year, the ore going to the mill will be fully up to average grade and of such quality that good recoveries can be made.

Construction and Operation at the Mill.—Grading for the plant was started early in July 1910, and the laying of concrete foundations was begun early in October. The

mill was then designed to be built in three sections, but subsequently, on account of the rapid increase of tonnage at the mine, it was decided to add two additional sections and build the plant with a capacity of 5000 tons per day. The first section was completed and started on October 16, 1911, about fifteen months after the commencement of construction work. The second section was put in commission about the end of December, and the third section was placed in operation on April 1, 1912. The fourth section will be ready to start about June 1, 1912, and the fifth section before the first of September. The two sections now in operation have demonstrated a capacity of more than 1000 tons per day each during the months of February and March, and it is proved, therefore, that the completed plant will readily have a capacity of 5000 tons per day.

The power-plant, designed primarily for the requirements of a 3000-ton concentrator in addition to the requirements of the mine, has proved ample in capacity to accommodate the enlarged concentrator, and it will not be necessary, therefore, to extend this department. The mill, power-plant, shops, and other buildings are of steel and concrete, and, therefore, fireproof. The four sources of water-supply serving the concentrator have been thoroughly developed and equipped, and have proved capacities fully up to those anticipated. In connection with the mill the company has constructed and owns some sixty buildings, including offices, boarding-houses, and residences, for the accommodation of officers and employees. All of the buildings and improvements of the town of Hurley, excepting a few tent-houses, are owned by the company.

Since the first starting of the mill in November, no difficulties of importance have been encountered, either mechanical or otherwise, and it has been found that no alterations of any material consequence will be necessary, either as to design or methods of operation. The yield in pounds per ton of ore treated has been such that the commercial results have been very satisfactory under the circumstances. During the months of November and December, a comparatively small tonnage only was being treated in one section of the plant. This section started up in October on about 500 tons per day, and the usual adjustments, incident to starting such an institution, prevented the average treatment of more than about 700 tons per day in December. The yield for the entire period of copper contained in concentrate was a little over 24½ lb. The grade of concentrate was comparatively low, partly because it contained a considerable amount of carbonates, this resulting in correspondingly increased smelting costs; and operating costs, in general, were naturally high on account of irregularities of operation attending the starting up of a new plant, and, especially so, in connection with so small a percentage of its tonnage capacity. However, the total cost of producing copper for the full period the mill was in operation before the end of the year, was a little less than 10c. per pound. In January of the current year, on a yield of only a little over 22 lb. per ton and a tonnage rate of 800 tons per section for the two sections then in operation, the total cost per pound, including all expenses of every nature, was 8c. At the time of this writing, the final results are not available; but, during that month, the plant averaged in the neighborhood of 1100 tons per section for the actual running time of the two sections then in operation, and it is now estimated that the cost of producing copper for that month, on a yield per ton very similar to that for January, will not exceed 7½c. per pound. Approximately the same rate of tonnage, and conditions generally, are applying to March operations, and the costs stated will be improved as we can decrease milling and all other expenses through the treatment of larger tonnages and secure from the mine a better grade and quality of ore. Taken as a whole, the recoveries of the class of copper minerals reasonably amenable to concentration have been excellent, as high, in fact, as those of any other plant in the country with the operation of which I am familiar; and the design and arrangement of the plant, power-house, and all accessories are such that very cheap milling will be possible, and the results as to

milling costs, already achieved, indicate that our costs in this department will be considerably below our estimates.

The grade and quality of concentrate are proving to be what had been expected, and the smelting arrangement is, therefore, an economical one. The service of the Atchison, Topeka & Santa Fé railway in transporting ores from the mines to the mill and the concentrate from the concentrator to the smelter at El Paso, is proving entirely satisfactory. Power plant costs, even operating at small capacity, have already proved nearly as low as it was estimated they would be eventually at full capacity, and it therefore appears that this factor of cost will be substantially lower than had been expected. In fact, all elements in the situation warrant the assertion that, within the current year, the company will regularly produce copper at a cost substantially lower than has ever been stated in any official estimate or report.

Placer Mining in the Province of Quebec

By H. A. BALL

Placer gold was first found in the Province of Quebec 77 years ago, and mining has been carried on there in a desultory fashion ever since. The known area of gold-bearing gravel is small compared with the deposits of the Pacific Coast, although placer gold has been found in several counties of the province. These deposits have been examined, at various times, by men connected with the mining bureau of the Dominion, but they have had to work under great difficulties, chiefly owing to physical conditions resulting from glacial action, and no tenable theory concerning the origin of the placer gold found there has been advanced.

The principal district attracting attention at the present time is in the basin of the Chaudière river, where the mining rights to 70,000 acres of land in the seigniorie Regaud-Vaudreuil have been acquired by a Montreal company which has already done considerable prospecting and development work on the Gilbert, des Plantes, and Moulin rivers, the three principal gold-bearing tributaries of the Chaudière, in the seigniorie. The work of this company, the Champs d'Or Rigaud-Vaudreuil, has attracted considerable attention in eastern Canada, and has resulted in the locating, or blanketing, of all the available land in the neighboring Famine and du Loup rivers. The Quebec mining laws are very liberal, and for a fee of \$10 an individual may take out a miner's license entitling him to locate 200 acres of land, patented or otherwise. The surface of most of the land is patented, but, as a rule, the patents do not include the mineral rights, which are still retained by the Government.

According to government reports, more than half of the placer gold won in Quebec came from shafts and drifts in a pre-glacial channel in the Gilbert River valley. Royalty was paid on over \$1,000,000 in gold taken from a continuous strip of this channel, 1½ miles long. This strip escaped the destructive glacial movement which broke and displaced the rest of the gravel deposit in the Gilbert and elsewhere. Some of the mining companies working on the Gilbert paid small dividends, but owing to crude mining methods, poor labor, underground water and quicksand, irregularities of gold distribution, etc., reports show that the expenses generally exceeded the production, although some of the gravel was extremely rich. When the workings reached the point where the gravel was replaced by barren material, mining ceased on the Gilbert.

For eight months I directed the work of four drills in the Gilbert basin, searching for the continuation of the channel, but the pay-gravel seems to have been wiped out. At the upper end of the old workings I found a small block of virgin ground with four or five feet of rich bottom gravel capped by 40 ft. of clay, but persistent drilling upstream showed no further traces of this, although the val-

ley was closely drilled from rim to rim. Drilling downstream was also unsatisfactory. Early in 1910 I started the prospecting work on Ruisseau des Meules, a small tributary of the Moulin, with good results from the beginning, and by means of shafts and drifts blocked out a sufficient area of channel gravel to warrant the placing of the present plant. This gold-bearing gravel lies on a bench paralleling the supposedly original bed of the stream which is now filled with glacial débris. It consists of from 2 to 5 ft. of gravel lying on the bedrock. This gravel is peculiar, being composed mainly of clay-slate pebbles held in a mass of sticky yellow clay of the consistence of putty and rich in coarse, smooth, rounded gold. Over the gravel is a layer, several feet thick, of boulders and barren blue clay with a capping of boulders, loam, and sand, carrying a little gravel and fine flaky gold. The depth of this cap increased rapidly with the hill slope.

Ruisseau des Meules is flat and rather narrow, with steep hills on both sides. The bedrock grade is only 2.35%, which, with the limited supply of water, necessitates the elevating of the tailing. There is little water in the stream after the spring freshet, and in order to get water under sufficient head for hydraulicking it was necessary to tap Lake Fortin, nearly seven miles away. Across one end of the lake was built a plank-faced log-ribbed dam, 700 ft. long and 16 ft. high on the slope, making a splendid reservoir three miles long and one and one-half wide. From this the seven and one-half mile ditch delivers 1500 miner's inches of water to the penstock, 246 ft. above the bedrock at the mine.

The ditch digging was difficult and costly; nearly one-third of the line had to be blasted through tough slate bedrock; a large portion, passing through swamps and muck, had to be sheathed; over a mile of flume had to be built, the longest 700 ft. and the highest on a trestle 40 ft. high. For the work only 'jack-knife' carpenters were available, and labor new, even to the use of long-handled shovels. The ditch crossed dozens of the narrow little Quebec farms, and every foot, in fact every inch, of the right-of-way had to be bargained for and measured so closely that it was necessary to have a Government surveyor survey the ditch and the area to be paid for on each farm. All cuts over four feet deep had to be boxed, and the surface of the ground leveled; one to three bridges, of specified dimensions and material, had to be built on each farm; in many places the ditch had to be fenced on both sides; the slightest water seepage was sufficient to cause a claim for damages; even wheel tracks on frozen ground were made the basis of such claims. Many of these claims were so absurd that they would have been amusing if they had not been so annoying and expensive.

The pipe-line has a 42-in. intake at the penstock, tapering to 15 in. in 2000 ft., and it supplies water to two hydraulic giants working in the pit. It is tapped to furnish water-power for derricks, to prime the centrifugal pump of the elevator, and when the pump is not running, keeps a constant flow of water over the riffles in the sluice on the elevator. The sluice leading to the elevator sump is 3 by 3 ft., with a planed tongue-and-groove bottom. It is rifled longitudinally with second-hand steel—railroad rails laid bottom up and spaced with slip-blocks—thus making first-class riffles and an ideal surface for boulders to travel over.

The consulting engineer of the company and I planned the elevator to meet conditions existing on Ruisseau des Meules. It is really the digging end of a close-connected bucket dredge, with 3¼-in. ft. buckets. It has an hourly capacity of 180 cu. yd. of material raised 35 ft. above the bedrock, the buckets dumping into a rifled steel sluice which is lengthened as needed by wooden flume. The lower end of the ladder is in a bedrock sump at the end of the lower flume, which is fed by the hydraulic giants. The sump also accommodates the end of the suction pipe of the 12-in. centrifugal pump which supplies water to the upper sluice. The structural work of the elevator is of steel, built on an I-beam superstructure carried on four double-wheeled trucks. The wheels travel on heavy steel

rails, spaced 20 ft. apart. This arrangement was planned to facilitate the moving of the elevator, as the narrowness of the channel will necessitate at least one move in the middle of the water season, when time saved will be a great consideration. The elevator is run by electricity. Power is cheap, since coal is used for fuel and the powerhouse is on the railroad only $2\frac{1}{2}$ miles from the mine. It requires 30 hp. for the bucket-line and 110 hp. for the centrifugal pump. The mine is well lighted at night by arc lights, and the usual system of three shifts is used when there is water for hydraulicking.

With the exception of a few minor defects, and the mishaps usual when starting work with unskilled labor, which has to be trained to efficiency, the machine met all requirements in a satisfactory way. As the labor was ignorant of modern milling methods, and time was limited, it was necessary to send to California for three pipers so that work could start at the beginning of the water season. In opening the ground to the best advantage, the first season's work, 1911, had to be done in ground that had been worked in the best part of the channel by pick-and-shovel methods. This strip of partly worked ground, however, yielded an average of 36c. per cubic yard, and this season the work will be done in rich virgin ground which I tested thoroughly and for which the equipment was planned.

It would be difficult to predict the future development of placer mining in Quebec. Prospecting, as known in the West, cannot be carried on in a thickly settled country where the surface is jealously held by individuals, even if the prospector is licensed by the Government. Surface indications do not aid the prospector. He is hampered by the thick blanket of boulder clay which covers most of the country. This clay would render dredging unprofitable if otherwise possible, and shaft mining is expensive, owing to the large beds of quicksand and the great amount of underground water. Frequently this clay cap rests on the bedrock and replaces the gravel in the channels, and being barren it is a great obstacle to profitable mining in any case.

The climate is extremely severe, and surface mining cannot be profitably carried on during the long winters. The summers are short, and water fails early in spite of the abundant rains. Labor, while willing and cheerful, is untrained and very unreliable. This would be changed in time, but it is a serious drawback at present. On the other hand, some very rich beds of gravel have been found, and, with the expenditure of sufficient money, water can be obtained for working them, as there are many large lakes available for reservoirs. Canadian capital is generally willing to back Canadian enterprise and take a chance. The Champs d'Or Rignad-Vandreuil Co. is a good example of this spirit, and it certainly deserves success. Outside of the work in the seignior, little actual work or prospecting has been done. The locators of surrounding properties seem to be waiting to see if the one company succeeds in its venture, and I believe that the immediate future of placer mining in Quebec will be greatly influenced by this success or failure.

Precipitation of Gold by Colloid Gels

An interesting paper by E. Hatehek and A. L. Simon was read at the last meeting of the Institution of Mining and Metallurgy, describing experiments by Mr. Hatehek in the domain of colloidal chemistry. The object of the experiments was to explain the presence of gold in the middle of solid quartz, and also the banded form of quartz structure. Thomas Graham in 1861 discovered the difference between aqueous solutions of crystalline and colloidal substances, and the fact that the former would diffuse into and out of the latter. Subsequently R. E. Liesegang applied the principle in photographic work with the gelatine gel. He discovered that if a drop of an aqueous solution of silver nitrate was placed upon a film of gelatine containing bichromate of potash, the nitrate would diffuse

and react to form bichromate of silver; and that the reaction would not spread as a uniform halo, but as a series of concentric rings. Beechhold, Ziegler, and Hatehek have continued investigations into this phenomenon by means of test-tubes, the gel containing one of the reacting components being placed in the lower part, and the other component in aqueous solution being poured on the top of the gel. Hatehek especially investigated the possibility of reducing gold salts contained in a gel of silicic acid. He half filled the test-tube with silicic acid to which 1 to 2 c.c. of 1% gold chloride solution was added, and allowed the mixture to set. In one set of experiments the reducing agent was then added in the form of aqueous solution such as oxalic acid or ferrous sulphate, and in another set the tube was introduced into an atmosphere of reducing gas such as sulphur dioxide, hydrogen, or carbon monoxide. The authors described the results obtained and showed how the gold is precipitated generally in layers in the gel, occasionally being deposited in crystalline form. They found that the best crystals were obtained with reagents not readily soluble in water. In some cases a black substance, probably carbon, was also precipitated. The authors discuss in detail the application of their researches to the formation of gold-bearing quartz veins. The reception was decidedly mixed and the comments were keen. The general opinion was that a watery gel had not the power to exert dynamic force, and that the loss of the water subsequently was a difficult point to explain.

Laramie Tunnel Record

In a recent paper in the *Bulletin* of the American Institute of Mining Engineers, D. W. Brunton gives the following details regarding the record work done in driving the Laramie Poudre drainage tunnel in Colorado.

During March, April, and May 1911 the record for distance driven, drilling, powder consumed, and cars of waste sent out was:

	1911		
	March.	April.	May.
Feet of completed tunnel	653	588	635
Number of holes drilled.....	1,965	1,759	1,985
Linear feet of holes drilled.....	14,330	12,510	15,263
Average linear feet of holes drilled daily	154	139	164
Sticks of powder used.....	14,808	16,171	18,311
Cars of waste sent out.....	4,983	4,765	5,156

Considering the hardness of the rock, the speed attained in drilling, as shown by the figures above, was exceptionally good; but even these averages fall considerably below what was possible with the equipment used. For instance, a number of the best drill-runners were able to average over 60 ft. of holes per shift, one of them making a monthly shift-average of 61.68 ft., another of 61.75 ft., and a third of 61.86 feet.

Siberian Gold Deposits

Siberian gold deposits are attracting the attention of capital, and two Russian engineers have received permission to form a company with \$1,030,000 capital to operate in the Amur territory. Several French companies have been formed; the Compagnie des Mines d'Or Sayansk will invest large sums in Siberia; another company is prospecting on the shores of Lake Baikal, 40 miles from Irkutsk, an Australian dredge being already at work in this field; and large French investments have been made in the south Transbaikalian goldfields, on the frontier of Mongolia. During the summer the Orsk Goldfields, Ltd., will begin production near Bolba on the Amur, in addition to its present output. The Imperial Geological Survey has sent two men to Yakutsk to investigate the discoveries near there. The Russian ministry has submitted to the Council a draft of a new mining law which provides that lands which are "manifestly gold bearing" shall no longer be open for prospecting, but shall be investigated by the Government and afterward sold at auction.

Metal Production in the Central States

Final figures covering production of lead, zinc, copper, and silver in Michigan, Wisconsin, Kansas, Arkansas, and Oklahoma in the year 1911 have been compiled by the United States Geological Survey and were distributed this week. The figures for Michigan were collected by B. S. Butler, and those for the other states by J. P. Dunlop. Summaries are presented below.

Michigan mines in 1911 produced 219,840,102 lb. of copper, valued at \$27,480,013, and 497,281 fine ounces of silver, valued at \$263,559, a total value for both metals of \$27,743,572. This is a decrease in value of \$715,698, or about 2.5%, from the 1910 production, due to a slightly smaller output of copper and a little lower average price for the metal. Owing to this slight decrease in the price of copper there was a decline from \$2.54 in 1910 to \$2.50 in 1911 in the average value per ton of ore treated. The recovery of refined copper per ton of rock milled in 1911 was 20 lb., compared with 20.5 in 1910. The quantity of silver recovered was 497,281 fine ounces, an increase of 166,781 oz. over that of 1910. Of the silver, 513 oz. was obtained as pickings and 496,768 oz. was derived from the electrolytic treatment of 43,755,777 pounds of copper. The mines of Houghton county produced 83.9% of the copper and 92.4% of the silver output in 1911. The value per ton of ore or 'rock,' according to Michigan usage, was \$2.54 in 1910 and \$2.50 in 1911. Further details are given in the table below.

4359 tons in 1911. The sphalerite concentrates sold increased from 89,232 tons to 93,963 tons, and the zinc carbonate concentrates declined from 5269 tons to 5035 tons. The metal content of the lead concentrates was 1060 tons less than in 1910. The recoverable zinc content of the sphalerite and carbonate of zinc concentrates increased 284 tons over that of 1910 and the value was \$480,120 greater. Benton, the largest producing distret, had an increased output of both lead and zinc concentrates. The value of the output from the Hazel Green district doubled that of 1910 and placed that district ahead of Platteville. The production of lead and zinc and the tenor of the ore and concentrates in Wisconsin in 1911 are shown in the following tables:

TENOR OF WISCONSIN CONCENTRATES, 1910 AND 1911.			
	1910.	1911.	
Total crude ore, short tons.....	1,032,052	1,123,040	
Total concentrates in crude ore, %:			
Lead	0.5	0.4	
Zinc	9.2	8.8	
Metal content, %:			
Lead	0.4	0.3	
Zinc	3.2	3.1	
Lead content, %	78.7	76.9	
Zinc content of:			
Sphalerite concentrates, %.....	34.8	34.6	
Zinc carbonate concentrates, %.....	29.9	33.1	
Value per ton of:			
Lead concentrates	\$51.09	\$52.41	
Sphalerite concentrates	\$19.62	\$20.53	
Zinc carbonate concentrates.....	\$13.21	\$14.72	

From Kentucky no galena concentrates were shipped to the smelters from the fluorspar district, and in consequence no production of lead and silver was reported. The production of zinc carbonate concentrates in the state amounted to 467 tons, valued at \$10,604. The average zinc assay was 40%, and the recoverable spelter content of the concentrates was 158 tons. As only 30 tons of zinc concen-

In Wisconsin the value of the mine output of lead and zinc was \$3,582,006. The value of the production in 1910 was \$3,188,460, so that the increase was \$393,546. The lead concentrates sold declined from 5608 tons in 1910 to 4359 tons in 1911. The sphalerite concentrates sold increased from 89,232 tons to 93,963 tons, and the zinc carbonate concentrates declined from 5269 tons to 5035 tons. The metal content of the lead concentrates was 1060 tons less than in 1910. The recoverable zinc content of the sphalerite and carbonate of zinc concentrates increased 284 tons over that of 1910 and the value was \$480,120 greater. Benton, the largest producing distret, had an increased output of both lead and zinc concentrates. The value of the output from the Hazel Green district doubled that of 1910 and placed that district ahead of Platteville. The production of lead and zinc and the tenor of the ore and concentrates in Wisconsin in 1911 are shown in the following tables:

In Kansas the value of the mine production of lead and zinc was \$1,428,318, which is \$212,670 less than the value

of the production in 1910. The production of lead concentrates in the Galena district was 3487 tons, compared with 2508 tons in 1910. The shipment of zinc concentrates (all of which was sphalerite except 122 tons) was 17,892 tons, a decrease of 3062 tons. The lessened value of the output of zinc in the Galena district should not be construed as an indication of a declining field, for the development of new mines and opening of old properties was more general than for several years. The decrease rather marks the transition stage of the field from one of many small operators to one having the active development

shipped an increased tonnage of zinc carbonate and silicate, the high price paid having stimulated the production during the last few months of 1911. The production of lead concentrates in the Quapaw district increased slightly, but the shipments of blende concentrates declined 1676 tons, or over 40%. In the Miami district the production was less than in 1910, but development was very active. A lower run of ore was proved by systematic drilling on the land of the Miami Royalty Co. and the Emma Gordon Mining Co. New shafts were sunk to the orebody and some ore was hoisted from the lower levels. Work in the

centralized in individuals and companies financially able to mine on a more extended scale.
In Oklahoma the value of the mine production of lead and zinc was \$812,190, a decrease of \$132,506 compared with the production of 1910. The shipments of both lead and zinc concentrates were less than in 1910. The mines of Murray county, in the Arbuckle Mountain region, produced 25 tons of sphalerite and 195 tons of zinc carbonate,

mines was hampered by water, which made it necessary to install pumps of large capacity. Several new concentrating plants were erected and others contracted for, so that operators predict a very much larger output from this district in 1912.
The Arkansas mine output of lead and zinc was worth \$81,456, compared with \$112,896 in 1910. While there was a decreased production of zinc, development was active and

only a few tons more than in 1910. The rest of the year's production came from Ottawa county, in the extreme north-eastern part of the state. The mines of the Peoria district

new milling plants were constructed, which are now in operation. The galena concentrates sold in 1911 amounted to 80 tons, containing 64 tons of recoverable lead, valued at \$5760. The sphalerite concentrates sold in 1911 amounted to 1407 tons, and the zinc carbonate and silicate concentrates to 183 tons. The total recoverable zinc content (allowing for smelting losses) was 664 tons, valued at \$75,696.

Dividends

The TONOPAH EXTENSION MINING Co. has declared a dividend of 2½ per cent.
April dividend upon the shares of the MINES COMPANY OF AMERICA has been postponed.
The SEVEN TROUGHS COALITION MINES Co. has declared dividend No. 1, of 2½c. per share, payable July 1.
The AMERICAN SMELTING & REFINING Co. has declared a dividend of 1¾¢ on preferred shares and 1% on common shares.

Discussion

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Insertion of any contribution is determined by its probable interest to the readers of this journal.

Australian Mining Laws

The Editor:

Sir—I notice some discussion in the San Francisco section of the Mining & Metallurgical Society of America with regard to Australian mining law. In a general way, the Australian law has one great advantage, and that one is the vertical side-lines. In America, 99% of the litigation has arisen over the extralateral right, and, with this one element eliminated, mining law becomes simplicity itself. On the other hand, the Australian form of claim, which is that of a lease contingent upon the continuous performance of labor requirements, is open to very deep-seated economic criticism. I have not the time to go into the matter thoroughly, but in a general way I may point out the main objection.

It fundamentally works to the disadvantage of the individual prospector and of the industry, because unless the prospector can get his claim on an immediately self-supporting basis, he is sooner or later compelled to abandon it. But of wider importance than this is the fact that it to a great extent bars the common miner in the district from becoming a prospector, for he must employ a large part of his time earning wages and, as the law requires continuous work on leases, obviously he could take no interest in prospecting. There are cases where a few working miners subsidized one of their number to do the prospecting, but this in turn works to their ultimate disadvantage as it makes for divided ownership and divided counsels and uncertain support. Given that a vein has been found which does not at once show up an ore-shoot, and as long as a vein has an owner he will, nine times out of ten, return to do more work. More especially is this the case among the miners who, as I have said above, can only devote a limited portion of their time to such effort.

It compels the capitalist, in the shape of the exploration company, to continue to spend money on development which may be perfectly useless and often at times which may impose particular hardship from a financial point of view. The result of this has been to drive the exploration companies practically out of the business of preliminary development, and such companies in West Australia are not now prepared to undertake anything that is not developed to a considerable extent by prospectors. On the other hand, as the prospectors must live, their tendency is to root out the ore as fast as possible, and they therefore have but a poor showing to make to the exploration company.

The result of this, to my mind, has been to greatly retard the development of such mining regions as Western Australia. Some years ago I had occasion to look into the matter, and at that time, so far as I recollect, over 12,000 claims had been pegged out and some 3000 of these had actually produced ore of payable grade, and at the present moment I doubt where, eliminating claims taken up merely to protect the large mines, there are more than 1500 leases to which the legal title is still sound. In other words, a large majority of the claims taken up have been absolutely abandoned and practically forgotten.

There is another point, the bearing of which is rather difficult to state, and that is that companies operating valuable mines, in case of strikes, for instance, might be unable to man their leases and therefore undue pressure could be brought to bear by the Government upon them. I do not know that this has ever occurred in Australia, but the possibility of such pressure might very well lead to injustice.

Altogether, with a considerable amount of experience in both America and Australia, my emphatic view is that the American system of giving a title in fee simple after a certain amount of limited work over a short period, is one of the best for the ultimate development of the industry, and the one in the best interest of the population as a whole, and especially of the working miner, who thus has an opportunity to improve his position from that of a wage-earner. It has to be borne in mind that the development of mines in the early stages, particularly over the first three years of their history by and large, is a losing business, and I imagine one in which actually 90% of the value of the labor and money expended is lost. Given that we have got such a state of things, from the very nature of our industry, if we are to get three years of preliminary work done, it has got to be in effect subsidized from some quarter, and this subsidy lies in the fact that the wage-earning miner will devote his own labor and some of his accumulated savings to this work. If, on the other hand, any form of law is put in force which discourages him from this, it means the ultimate curtailment of mining development at its very root, and to my mind that is the evil from which Australia is suffering today. That country is potentially one of the greatest mining countries in the world, and yet the proportion of new mines which have come forward during the past ten years has been ridiculously small. In other words, the population is not engaged in sowing the seeds of mining development which ultimately result in a certain definite new crop of substantial mines, such as in the United States.

It may be said in opposition to the above that under the Australian form of law, exemption is given sometimes from this continuous employment of labor, in order to encourage men or to meet their necessities. This, however, is a matter of favor; it is not a matter of right, and the exemptions are zealously guarded. In any event, although the actual administration of the law might be very liberal, the fear of its conditions has been sufficient to stifle the industry.

London, April 25.

H. C. HOOVER.

Government Bureaus and Potash

The Editor:

Sir—In your issue of May 11, J. D. Kennedy of Manhattan, Nevada, makes some allusions to the potash prospecting enterprise in Railroad valley, Nevada, which, whether intentional or not, are unfair and based upon error as to facts, and as president of the Railroad Valley Saline Co. I desire to state the facts. This company is now drilling a test-hole in the salt marsh of Railroad valley with the hope of discovering a valuable buried deposit of soluble potash salts. This hole is now about 600 ft. deep. This enterprise was started nearly a year ago as a result of the general potash agitation; but this location was decided upon partly because it was a matter of public record well known for the past thirty years, that the surface salts of Railroad valley carried a remarkable amount of potash, and partly because the examination of various engineers determined that the geological surroundings and drainage conditions of the Railroad valley marsh were at least as favorable as any other locality for a possible concentration of potash salts during former lake periods. It is only since last October that representatives of the U. S. Geological Survey and the Bureau of Soils have at different times examined Railroad valley as part of the general field of research of these bureaus. They have spent an aggregate of nearly three weeks in Railroad valley and taken over 200 samples of waters and soils, with results, so far as published, confirmatory of the earlier private reports. It still remains to be proved that there is any extensive deposit of potash salts in Railroad valley, or if there is, that these could be manufactured to commercial form and marketed at a profit.

The Railroad Valley Saline Co. is a Nevada corporation, a mutual association of many of the leading mining men of Nevada and their personal friends in San Francisco and the East, all of whom fully understand the nature of the

gamble taken, and at the very start marked off as a loss all moneys risked in the enterprise. The company's capitalization is 100,000 shares of assessable stock, and it publicly invited the support of "only those who would cheerfully lose if final results were adverse." Its weekly reports of progress and results are officially published in the *Tonopah Miner*, and all interested parties as well as the government bureaus have been invited to examine the drilling and its log samples, in the hope that scientific and other public benefits might be secured from the undertaking, even if no valuable deposit of potash was found. In the incidental results to date of starting a 'good roads' campaign and providing artesian conditions in a great valley, the enterprise has already justified itself even in a commercial sense.

We do not know of any parties in Manhattan or elsewhere who have invested money in Railroad valley in potash locations or otherwise without a full knowledge of the exact conditions and willingness to take a long chance as much for the spirit of public enterprise as for possible profit.

San Francisco, May 22.

VICTOR BARNDT.

Experimental Work on Manganese Silver Ore

The Editor:

Sir—In testing some manganese silver ores in 1910 I had an experience similar to that of E. M. Hamilton published in the *Mining and Scientific Press* of December 4, 1909. From his results he summarizes the following in addition to a chloridizing roast as giving good cyanide extractions: (A) preliminary to roasting with sulphur in the absence of air, (B) preliminary treatment with alkaline sulphides, (C) preliminary treatment with hydrochloric acid, (D) preliminary treatment with sulphurous acid.

In the tests on the ore that came under my observation, it was discovered that the ore in place would give about 65% extraction, while the fillings with about the same manganese content yielded 85%. These fillings had been standing approximately 25 years and contained considerable organic matter. Calcium carbonate was the principal constituent of the gangue of both ores and fillings, but some small amounts of ore from near the surface contained no carbonate and were distinctly acid in character. In the chemical examination of the ore and filling it was found that in the ore the manganese existed principally as MnO₂, while in the fill it was mostly in some lower form of oxidation, possibly as MnO. With this as a basis I carried out the following experiments:

About 10 kg. of ore was crushed to 1/4-in. mesh, half mixed with a little manure and 1/4 kg. of sawdust dampened and allowed to stand with occasional dampening and stirring for 30 days. The organic matter was carefully screened and washed out, the sample crushed to 150-mesh and cyanided. This gave 75% extraction as against 67% for the untreated half of the sample. Reduction tests were tried with the following reagents:

FeSO₄. Liberated Fe₂O₃, coloring the yellow ore. The possible reaction being as follows:

3MnO₂ + 6FeSO₄ = 2Fe₂(SO₄)₃ + Fe₂O₃ + 3MnO

FeCl₂. Action similar. With NH₄Cl added, the reaction is apparently more complete, as MnO is soluble to some extent in NH₄Cl. (Corney's Dictionary of Chemical Solubilities.)

Sulphites gave no reaction.

Na₂S in 20% solution bleached the ore almost white. Treatment with a 1% solution showed a very small increase in extraction.

Alkaline oxalates gave no reaction.

Oxalic acid in presence of sulphuric acid on acid ore gave 90% extraction.

Hydrochloric acid gave (1) 71% extraction, (2) over 90% extraction.

FeSO₄ experiments: The FeSO₄ was allowed to act for 6 hours; 250 gm. ore used to 1000 c.c. of each strength

solution. Ore ground to pass 150-mesh. This ore contained over 20% CaCO₃.

Number	Strength FeSO ₄ Wt. (%)	Value Ore gm. Ag	Value Tailing gm. Ag	Extraction, %	KCN cons'd kg.
1	3	418	101	75.8	3.75
2	2 1/4	418	105	74.8	3.45
3	1 1/2	418	122	70.8	2.35
4	1/4	418	132	68.8	2.23
5	3/8	418	123	70.5	2.04
6	untreated	418	146	65.0	2.06

TEST ON ACID ORE					
Number		Ore, gm. Ag	Tailing, gm. Ag	Extraction, %	
1.	Untreated	1211	673	44.4	
2.	Reduction with oxalic acid in presence of H ₂ SO ₄	1211	117	90.3	
3.	HCl treatment	1211	350	71.0	

In the above tests the ore was ground to pass 150-mesh. For No. 2 test 18 gm. oxalic acid was used with 500 c.c. of 1% solution of H₂SO₄. For No. 3, 500 c.c. of 1% solution of HCl was allowed to act 1 1/2 hours.

I am inclined to think that the low extraction of No. 3 was due to an insufficient quantity of hydrochloric acid, as a test on another sample with a larger quantity of HCl gave an extraction of over 90%. In the untreated ores, the extraction of the gold varied between 65 and 84% without any apparent relation to the behavior of the silver. I hope others who have had more experience than myself will come forward with their results, and I would like to advance the following suggestion for discussion. That it is the state of oxidation of the manganese that is at least partly responsible for the poor results on these ores. That as the cyanide penetrates the manganese dioxide to the enclosed silver particle it is slowly oxidized to cyanate, carbamide, or perhaps carbonate (which have no action on silver sulphide) according to the well known equation representing the ultimate decomposition of cyanide exposed to air and moisture. At all events, it seems probable that, whatever the relation between the manganese and the silver, the addition of some suitable reducing agent would have a beneficial result on the silver extraction of these ores.

BYRON JACKSON.

San Francisco, April 8.

Copper Smelting in Siberia

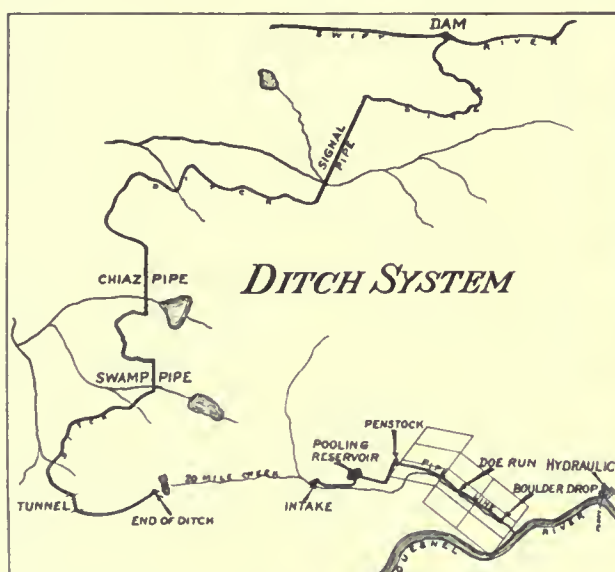

On September 10, 1911, a new copper smelting works was started in Siberia on the River Ulen in the district of Minusinsk of the Yenissei government. This business owes its existence to the energy of a young mining engineer, M. Ph. Delaru, who at his own risk began investigations in the year 1905. When, in 1907, he had acquired sufficiently encouraging results, some Moscow capitalists joined him and a modest plant was started. At present the smelter produces matte only; for, in consequence of the great difficulties in delivering the machinery, the plant is not yet quite finished. The correspondent of the *Gorny Journal* who makes this report says that he was particularly struck with the completeness and efficiency of the arrangements and plant as far as it was constructed and working in 1911. The great interest of the plant is because it is one of the first in Siberia.

Special Correspondence

BRITISH COLUMBIA

NEW COMPANIES IN THE FIELD.—PLANT OF THE QUESNELLE COMPANY.—MOTHERLODE BEGINS WORK.

The outlook for mining in British Columbia for the current year is more promising than at the corresponding period of recent years, as the following brief summary will indicate. Hydraulicking operations will be larger on the whole than for some years, for in addition to those in the Atlin division of the Cassiar district and the Cariboo division of the Cariboo district, there are those of the Quesnelle Hydraulic Gold Mining Co. in Quesnel division, Cariboo, which has not previously produced. Lode gold mining has had the addition of the operations of the Motherlode Sheep Creek Mining Co., which commenced crushing early in May, besides which the Hedley Gold Mining Co. may be expected to increase its output this year. Silver and lead also will probably show an appreciably large increase, for the Sullivan mine in East Kootenay promises in a large measure to compensate for the loss of output caused by the closing of the St. Eugene; while in Ainsworth di-

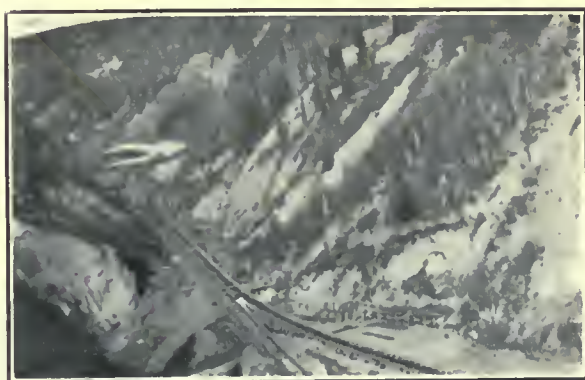

DITCH SYSTEM, QUESNELLE HYDRAULIC G. M. CO.

vision the Blue Bell and several smaller mines, non-productive in 1911, are on this year's list of producers; and Sloean will have the Rambler-Cariboo, Rio, Sloean Star, Standard, and several others to increase its production of these metals. Then the large copper mines—Granby, British Columbia, and Britannia—give promise of making an increased output, and will also add their quota of silver and gold. The Centre Star group and Le Roi No. 2, in Rossland district, are maintaining their production of gold-copper ores; indeed the former, now that the Le Roi has been added to it, is increasing its output. In the Coast district the Marble Bay mine, on Texada island, is the only noticeable producer in addition to the Britannia; its ore yields gold, silver, and copper, and its production continues to be satisfactory. Zinc is the only other metal produced in commercial quantity in the province. The provision of railway transportation facilities for the Lucky Jim mine, Sloean, which has been without them since July 1910, will allow of shipment of crude zinc ore from that property, while silver-zinc concentrate will continue to be shipped from two or three Sloean concentrating plants. Coal mining appears to have improved prospects, for working conditions are normal in the Crow's Nest district, southeast Kootenay, after the long strike of last year, and Vancouver Island collieries find the demand for coal active.

Mention has already been made of two new companies, the operations of which are expected to add to the mineral production of 1912. Further brief notices of these may be

of interest. The Quesnelle Hydraulic Gold Mining Co. is financed chiefly by New York and Philadelphia capitalists. Its water-supply system, completed last summer, covers a distance of approximately 25 miles from the dam on Swift river to the dump on Quesnel river. An important feature is that it includes three inverted siphons of wood-stave pipe, 5 ft. diameter and aggregating 9000 ft. in length and having a capacity of 60,000,000 gal. of water every 24 hours. Another noteworthy fact is that high-carbon steel plates and manganese-steel rails have been placed in the sluiceways. Last winter 85 tons of plates and 25 tons of rails were hauled more than 200 miles, from the Canadian Pacific railway at Ashcroft to the mine. The 40-lb. steel rails have been put in along 200 ft. of the sluiceways; eventually there will be a length of 300 ft. The steel plates are 58 in. square, and their carbon content varies from 0.80 to 1.20%. They are spaced 2 in. apart in the sluiceway and each plate is placed half an inch lower than the preceding one. The company's 10 hydraulic leases cover approximately 800 acres of gravel beds. It is estimated that there is, along a well-defined old river channel, a body of auriferous gravel approximating 100,000,000 cu. yd. in quantity. A preliminary run late last season allowed progress toward opening the pits; this season's operations were

SLUICEWAYS, QUESNELLE HYDRAULIC G. M. CO.

commenced on April 15, which is about a month earlier than is usual in Cariboo district.

The Motherlode Sheep Creek Mining Co., which commenced crushing ore early in May, is a Maine corporation, in which the principal shareholder is John McMartin, well known in connection with the Nipissing, La Rose, and Hollinger mines in northern Ontario. William Watson, of New York, is vice-president and general manager, and under his direction the mine has been developed to a depth of 500 ft. below the outcrop and a 3-years supply of gold-bearing ore for the 10-stamp mill blocked out. The mill and cyanide plant include a Blake crusher, ten 1250-lb. stamps, Merrill sizing cones, tube-mill, amalgamating plates, Dorr thickeners, Aldrich slime pumps, four 8 by 25-ft. Paehuea tanks, cyanide vats, Merrill clarifying and precipitation presses, etc. Water is brought in first by two red-fir continuous-stave pipe-lines, 2100 and 4500 ft. long, respectively, and then by 7000 ft. of steel pipe, grade 6 to 14 in., delivering water at the mill at 600 ft. effective head. Power is obtained from six specially designed Pelton water-wheels, which will drive all mill machinery and a compressor having a capacity of 1440 cu. ft. of free air per minute. The aerial tramway from mine to mill is 3600 ft. long, with about 1000 ft. difference in elevation of terminals.

LONDON

NICKEL IN EAST GRICQUALAND.—MODE OF OCCURRENCE.—THE STORY OF BROKEN HILL.

Attention has recently been drawn in London to the copper-nickel deposits in East Griqualand, South Africa. This district is part of the Cape Province and adjoins Natal and Basutoland, and the tract of country where the deposits are found is on the outlying spurs of the Drakensberg mountains. To be precise, the ore is found at Mount

Ayliff in the Insizwa range, 100 miles southwest of Pietermaritzburg in Natal, and 50 miles from the east coast of the Cape Province. The occurrence of copper ore in this district has been known for twenty years, and a limited amount of prospecting has been done, but without any satisfactory results. The examination of the district by the Cape Geological Survey has given a new impetus. The strata are bluish shales, flagstones, and thin sandstones, belonging to the Beaufort series of the Karroo system, and lying nearly horizontal. These beds have been penetrated by numerous intrusions of igneous rocks in the shape of sheets and dikes. Most of the igneous rocks may be classed as dolerite, but the great sheet of the Insizwa range and of the adjoining peaks and ridges partakes more of the nature of gabbro. The metamorphism of the strata caused by the igneous rocks is more pronounced than in the Karroo and Stormberg districts farther west. The copper-nickel ores are chiefly found at the contact of the gabbro and the altered sedimentaries. They are also found to a small extent as impregnations of the sedimentaries, but are more abundant in, and sometimes restricted to, the igneous rocks, of which they appear to have been an original constituent. The mode of occurrence is somewhat similar to that of the copper-nickel deposits at Sudbury, Ontario, and in Norway. Owing to the poor exposure of the base of the gabbro, the evidence of the presence of ore can only be obtained by sinking, and this has been undertaken where the rocks are stained with carbonate of copper or with silicate of nickel, in the presence of limonite, chalcopyrite, and pentlandite. The ores can be generally separated into two groups, one consisting chiefly of chalcopyrite, and the other richer in pyrrhotite and pentlandite, but the character of the ore varies so much and the minerals are so finely divided, that it is doubtful whether the nickel and copper minerals could be separated by ordinary ore-dressing methods. Bornite is also found in thin layers along joints in altered sandstone close to the contact. Niccolite, the arsenide of nickel, has been found in thin veins in the foot-wall in one of the workings. Platinum has been detected in varying amounts, and is considered to be in the form of sperrylite, the arsenide of platinum. In one case it has been found in a sample of ilmenite. The assays of a large number of samples have shown the copper to average 4%, the nickel 3.8%, and the platinum $2\frac{1}{2}$ dwt. per ton. The Cape government is affording every facility for further prospecting of this deposit.

The story of the British Broken Hill mine constitutes one of those romances that touch the imagination of the adventurous. Eighteen years ago the mine appeared to be on its last legs; the shares stood at half a crown, and there was talk of selling all available assets for 5s. per share, the capital consisting of 300,000 shares. Since then dividends to the amount of £412,500 have been paid, and the shares are now quoted at 60 shillings. At the time of reorganization, in 1894, the working capital had been reduced to £40,000 and the mine was only opened to the second level. After the oxidized orebody had been exhausted, the prosperity of the mine seemed at an end. The metals that rendered the ore valuable had fallen in price, the treatment of the complex sulphide ores was a problem then unsolved and apparently unsolvable, a drought was impending, and the labor position was unfavorable. A turn for the better came with higher metal prices in 1905, the production being greatly increased by solving the zinc problem and the consequent sale of tailing to the Zinc Corporation. This interval of prosperity proved brief. In 1907 the base metals declined in price, the grade of the ore was low, and the mill extraction was disappointing. The next two years were gloomy. It is true that in 1909 a new orebody was cut at the No. 8 level on Block 16, but further exploration appeared to indicate that it was unimportant. Conditions were so hopeless that the mine was then shut down. In June 1910 mining and milling were resumed, and early in 1911 exploratory operations were again started. This was rendered possible

by the issue of £30,000 in debentures. Good fortune waited on technical skill, backed by financial courage. A magnificent orebody was found by cross-cutting and diamond-drilling. Bore-holes on the No. 6 level first cut into the ore, the maximum width being 153 ft. Since then it has been proved from the No. 3 to the No. 9 levels. Not less than 2,000,000 tons of ore, calculated to yield a profit of £1 per ton, is said now to be available. At the annual meeting it was proposed that a bonus be given to the mine officials, and that the directors be invited to resume the receipt of the full fees authorized. No man is more deserving of thanks from the shareholders than W. H. Woodhead, the managing director of the British Broken Hill.

BLACK HILLS, SOUTH DAKOTA

AUTOMATIC ELECTRIC PUMPS AT THE HOMESTAKE.—RICH ORE IN THE WASP.—PROGRESS NOTES.

Installation of electric pumps to handle the underground water at the Homestake will be the next matter taken up in the electrification of the plant. Under the plan as outlined, water from all the levels will be drained to the Old Abe shaft, and in the stations of this shaft at the 500', 800', 1100', and 1400-ft. levels electric-driven pumps will be placed, with a capacity of 1000 gal. per minute each. These will hoist the water to the 200-ft. level, from which point it will be conveyed in a flume, by gravity, to the surface. Should it be needed in the mills, a pump installed at this point will raise it to the mill tanks. Eight pumps in all will be placed on the lower levels, as at each of the four levels they will be in duplicate. Worthington pumps, driven by Westinghouse motors, will be used. The switch controlling the motors will be operated by a float resting upon the surface of the water in the sump; the raising or lowering of the water-level thus starting or stopping the pump. The sumps are of a uniform size, 23 by 23 ft., roofed over with steel I-beams and reinforced concrete. Upon these roofs will be placed the pumps and motors. This electrically-operated pumping equipment will make it possible to dispense with a Cornish pump at this shaft that has operated efficiently for a third of a century. The Old Abe shaft is being deepened, sinking having been in progress for nearly a year, and it is now the intention to keep it always a little deeper than the Ellison, which is the principal hoisting shaft of the Homestake.

Although considerable secrecy was maintained in connection with the arrangements, it is now definitely stated that it was J. T. Milliken, president of the Golden Cycle Mining Co., of Cripple Creek, who furnished the money for liquidating certain obligations of the Columbus Consolidated company. The obligations were for delinquent taxes in Lawrence county, \$16,235; judgment to Fred Rossiter, \$10,032; judgment to C. D. Taggart, \$5018. The time for redemption of these judgments expires on October 5, 1912, and unless they are cancelled, Mr. Milliken will secure the property. The tax certificates have a longer time for redemption. The property covers over 600 acres, adjoining the Homestake on the north.

A recent discovery of high-grade ore has been made at the Wasp No. 2, where, under the quartzite, a 2-ft. vein that assays \$21 to \$417 per ton in gold has been found. The management is confident that the ore will average above \$200 per ton. From appearances it is a segregated shoot, and may or may not continue for any great distance. The ore is being sacked for shipment to a smelter. The mill is running steadily at a capacity of nearly 500 tons per day, on ore that goes a little better than \$2 per ton. At the director's meeting held on April 15 a dividend of 2c. per share was declared.

Mining men of this section were gratified to hear of the action of the House of Representatives in appropriating funds for the maintenance of the United States assay office at Deadwood. This office is doing valuable work for the local miners, and they would regret to see it closed. Some very rich ore, some of it liberally sprinkled with free gold, has lately been found on the Evans Consolidated property.

where development is under way in charge of C. C. Forster. The ore comes from a vein in the porphyry, and has every indication of permanency. Del Canfield is running the Golden Summit mill, at Hill City, on ore that will average \$25 per ton, free milling. This is taken from the vein containing the phenomenally rich streak, 2 in. wide, which was sacked for shipment. Returns from this shipment have not been received, but it is believed that the ore was worth a dollar a pound.

TORONTO, CANADA

GOLD PRODUCTION OF PORCUPINE.—SHORTAGE OF WATER AND COAL.—NEW DISTRICTS ATTRACT ATTENTION.

The estimated gold production of Porcupine to May 13 is as follows: Dome, \$58,568; Vipond, \$6000; Hollinger, \$46,082; McIntyre, \$30,000; total, \$140,650. The Dome mill is still operating under difficulties as regards the supply of water, and has been working at less than half its capacity. The hummock of quartz from which the mine takes its name has practically disappeared, having been leveled down in the course of mining operations. Work on the Vipond and Hollinger mills, both of which were expected to open about the first of June, has been delayed by the breaking of the railway bridge over the Boston river, delaying the delivery of material. The plans of the Hollinger have been changed in consequence, and instead of waiting for the big crushers, the mill will be started with a small crusher now on hand, as soon as the tube-mills and cyanide plant are ready. The West Dome has laid off part of its day shifts only, owing to the shortage of its fuel supply. The company will be compelled to ship in coal at great expense in order to carry on the work. The Dome Lake will construct a mill of 10 stamps to be operated with tube-mills which will give a capacity of 100 tons per day. One shaft is down below the 100-ft. level, and another nearly to that depth. Driving has been done for several hundred feet, the vein showing a width of 4 ft., and sufficient ore to supply the mill for a year has been blocked out. At the McIntyre a quartz vein has been found in drilling at the west end of Pearl Lake on the strike of the extension of the Hollinger vein system. Shafts No. 1 and 4 are both down below the 200-ft. level in good ore, and stoping operations have been begun. The new orebody at the Davidson, operated by the Crown Chartered, is showing up well. It has been driven upon for 30 ft. with good ore in both faces and cross-cut for 20 ft. in ore. The Hughes will shortly install a compressor. Driving is being done at the 50 and 100-ft. levels, and the shaft will be sunk to 200 ft. Work at the Rea is to be resumed; a number of the shareholders also recently visited the mine and are satisfied that under proper management it will 'make good.' In case the necessary funds for development cannot be raised by a loan or a re-issue of stock, the property will be leased.

Many prospectors and mining men are going into the Kienawisik lake district, about 160 miles east of Cochrane, in Quebec province, and some 45 miles south of the new town of Hurricana on the Grand Trunk Pacific railway. It is reached from Hurricana by water, and a number of gasoline launches have been put on the route. A rush is anticipated as soon as the season is a little farther advanced. It is stated that good free gold discoveries have been made, and many well known mining men have acquired interests in the new camp. The extent and value of the deposits are so far largely conjectural. Another new field in which considerable staking has been done and which is attracting many Porcupine prospectors is Turnbull, some 15 miles to the southwest of Porcupine.

Bullion shipments from Cobalt for the current year to May 12 total 2,937,913 oz., valued at \$1,698,820, of which the Nipissing mine furnished 1,376,939 oz. The yield of the Meyer shaft during April was valued at \$184,271, and work at the third level shows that at places in the vein there are 10 to 12 ft. of milling ore. The adit at 60 ft. in shaft 122 is in 6-in. of ore almost half silver. Hydraulic

prospecting has been begun on the big Nipissing hill with a pump throwing a stream of 4800 gallons per minute, with the object of discovering veins which may have been missed in trenching. As soon as the water in Cobalt lake has sufficiently subsided, the Right of Way will begin work in its No. 2 shaft near the La Rose. A concrete bulkhead will be put in to keep the mine dry. Good ore is being taken from No. 4 shaft. The Nova Scotia will be offered for sale by auction on May 20. The controlling directors, J. A. Jacobs, D. N. Steindler, and M. B. Davis, endeavored to effect a compromise with the creditors, offering to advance \$60,000 to alter the mill and meet running expenses, but the creditors forced a sale.

SALT LAKE CITY, UTAH

OHIO COPPER AND THE WALL ROLLS.—EXPANSION AT PARK CITY.—END OF THE CONSOLIDATED MERCUR.

The Ohio Copper company is being watched with a great deal of interest in Utah, but just when it seems about to solve satisfactorily all its metallurgical and financial problems, something invariably happens to set it back. A short time ago glowing reports were being given out about the wonderful success of the Wall rolls, portraying remarkable economies and picturing immense profits in the future through their general adoption throughout the mill. Later came rumors that the corrugated rolls were a complete failure and that the Ohio Copper would sue E. A. Wall, the inventor, for damages. The truth lies between the two extremes. Those who have been watching closely the performance of the

OHIO COPPER CO. MILL

rolls say that they have many strong points, but they are far from perfect. The inventor has not been inclined to act on suggestions of other millmen as to possible improvements, and for some time he has been under treatment for his eyes and unable to give personal attention to the experiments. As a result, little has been accomplished toward perfecting the rolls and bringing them nearer the standard hoped for. Meanwhile the mill is doing fair work, handling close to 2000 tons daily, and the property is making money each month.

The Dern interests, previously identified with numerous large mining ventures, are turning their attention toward the old Ontario at Park City. The property has been under lease for some time to Henry W. Crowther and associates, and now the Derns have joined Mr. Crowther in the Mines Operating Co. to handle the property on a larger scale. George H. Dern, manager of the Consolidated Mercur, is in charge of the property. The capacity will be increased to 150 tons at once, and later to 300 tons. It is estimated by the engineers of the Mines Operating Co. that there are 700,000 tons of ore, worth \$6,000,000, available for treatment by concentration and cyanidation. This is ore which was left years ago because it was unprofitable under the old metallurgical methods.

The Consolidated Mercur has been dying a slow death for years. A year ago the directors warned the stockholders that if there were not more favorable developments, it would be necessary to abandon the property. After a

year of effort to develop new and profitable orebodies, the management now recommends the sale of the equipment and the abandonment of the mine. This will probably be done. The Consolidated Mercur was one of the pioneers in America in the adoption of the cyanide process, and was highly profitable for years. It has been kept in operation so long as it paid expenses out of consideration for the employees and the town of Mercur, but the management objects to running at an actual loss, without visible encouragement for the future. Lead producers are somewhat handicapped by the strike at the American Smelting & Refining Co.'s plant at Murray. Pending a settlement of this difficulty, the company is holding back lead ore shipments. The Daly-Judge at Park City is steadily improving its earnings. The report for the first quarter of 1912 showed net earnings averaging \$27,700 per month, or \$12,700 above the regular dividends. The cash surplus on April 1, was \$469,700.

NEW YORK

MINING COMPANIES AND THE INCOME TAX.—NEVADA HILLS REPORT.—HEINZE SUEB.—MEXICAN MINES STILL WORKING.—ZINC MINES PROSPEROUS.—GUGGENHEIMS AT MIAMI.

The matter of greatest interest to mining operators generally throughout the country transpiring during the past week in the East was the decision of Judge Lacombe in the United States Circuit Court in the matter of the United States Government v. The Nipissing Mines Co. The suit was based on the refusal of the Nipissing Mines Co. to pay \$8000 which the Government claimed to be due for 1909 under the corporation tax law. This tax is levied as 1% on the net income, and is computed by taking the gross income—in the case of a mining company being the value of the ore taken from the ground—and deducting items of expense and depreciation, and also deducting \$5000 which is exempt, only those incomes which are in excess of \$5000 being taxable. In the year 1909 the Nipissing company paid \$5000 under protest and refused to pay the additional \$8000 which the Government demanded. The matter was not of supreme importance to the Nipissing company except in so far as it was a test case, the effort being to establish, one way or the other, whether all mining companies must stand taxation on the present estimate of income. The point raised by the mining company was that its dividends are, as a matter of fact, a partial liquidation of assets and that the net income cannot be computed without allowing for depreciation an amount equal to the ore taken from the ground. One of the arguments of the Government, in the particular case under discussion, was that this contention could not be set up because the Nipissing company is a holding company. Judge Lacombe, however, accepted the theory that, for all purposes involved in the case, the two concerns are identical. Richard T. Green, the secretary of and general counsel for the Nipissing Mines Co., said in a recent interview regarding the case: "If we were to pay the tax on the dividends, it would be a double tax, a tax on principal as well as income, since the dividends—ore turned into money—are part of a constantly lessening principal." Judge Lacombe held that it was obvious that there was a depreciation as the ore was taken out. Some of the best posted mining men in New York claim that the Government will lose between fifteen and twenty million dollars of revenue if the position of Judge Lacombe is sustained by the United States Supreme Court. Officers of the Internal Revenue Bureau in Washington decline to make any estimate of the amount which would be lost in this way, but pointed out the fact that mining companies are one of the smallest branches of industry listed among those corporations which contribute in this manner. The point which is raised by the mining companies does not apply to the other industries—steel and cotton mills and similar industrial plants—and the mining industry pays but a small percentage of the total revenue so raised.

The Eastern share markets have been irregular, and there

has been an entire lack of anything approaching cohesion in the list. This holds true in large part as to copper shares as well as the various precious metal mines. Pittsburg Silver Peak has re-enlisted a part of the public following it once had, on the news that the long litigation—begun some 12 years ago—has been decided in favor of the present company by the Supreme Court of Nevada. If there is further litigation, the suit, as it now stands, must be taken to the United States Supreme Court. There has been quite a little activity in the various Tonopah issues. The leader in this market for some weeks has been the Tonopah Belmont, this issue having usurped the place so long occupied by Tonopah Mining of Nevada. The declaration of a dividend of 2½% by the Tonopah Extension Mining Co. is glad news to the many holders who long ago despaired of ever realizing anything on their investment. Tonopah Extension was much skyrocketed at one time, and through its connection with Mr. Schwab—the steel magnate of South Bethlehem, Pa.—gained a great deal of notoriety and a very large market following. It is stated, on apparently good authority, that Mr. Schwab still holds the greater part of his stock, not having liquidated it when he again turned his attention to the manufacture of steel products. Mr. Schwab is a striking example of the captain of industry who can step out of the harness, and later, on occasion, show ability to 'come back.'

It is a sign of general mining progress when a property such as Tonopah Mining, instead of working out its property and then going into final liquidation, takes up the examination of a further mining ground with the intention of continuing profitable operations for its shareholders. This has long been the idea carried out by English companies, and if it can be done on this side of the water without arousing criticism such as followed the purchase of the North Dome by the Temiskaming, or the purchase of the Santa Gertrudis by the Camp Bird, it will do much to increase interest in mining investments on the part of the general public. It rarely transpires that final liquidation of a mining property is carried out in a way that satisfies the stockholders. The Tonopah M. Co. management is making every effort to purchase a promising mining property which can be put in process of development while the present property is still a profitable producer.

The annual report of the Nevada Hills had a distinctly adverse effect upon the market, inasmuch as the depreciation, which was figured at \$42.67 per ton for the ore taken out, made a showing of a net loss of \$458,000. Nevada Hills has a large Eastern following, and if conditions are bettered, as the president, Mr. Wingfield, promises, it will be a great relief to those who have held the shares for several years without return or market action.

The Heinze troubles multiply. Recently F. Augustus Heinze made a determined effort to regain possession of a large amount of securities which he pledged as collateral with one A. D. F. Adams of Boston, attempting to reach by legal proceedings brokers who disposed of the securities for Adams to innocent holders. In this Heinze was unsuccessful, there being an entire failure of proof of any conspiracy to defraud on the part of the brokers who so acted for Adams. The loss so sustained by Heinze is said to amount to something more than a quarter of a million dollars. In addition to this loss, Edward J. Carter, director of the Stewart Mining Co., has brought suit against F. A. Heinze charging that Heinze has transferred 225,000 shares of the stock of the Stewart Mining Co. out of the treasury of the company without reimbursing the company, and that Heinze has appropriated \$40,000 of the company's funds without proper accounting. It appears that Heinze has difficulty in distinguishing between doing business and laying up a lot of trouble. Spectacular as his career has been, and profitable as it has been at times to himself, it appears now to be difficult to point to a single success that has not been snarled up beyond hope of disentanglement.

The old La Rose crowd have recently brought to the New York market the promotion of a mining enterprise from the Kootenai country in the southern part of British

Columbia. The new promotion is known as the Motherlode Sheep Creek Mining Co. The properties are about 12 miles from the village of Salmo on the Spokane & Nelson, a branch of the Great Northern railroad. The property has a 10-stamp mill, is equipped with tube-mills, steel tanks, and a hydro-electric plant owned by the company. It is a gold producer, the process consisting of fine grinding and cyaniding.

Not all of the Mexican properties are greatly disturbed by the revolution. The Amparo reports for the period from January 1 to March 25 a crushing of 21,343 tons and a profit of \$82,614. The Greene-Cananea is breaking its best previous records. In April it turned out 4,654,000 lb. copper, with 154,597 oz. silver, and 627 oz. gold, and is expected to turn out an additional 1,000,000 lb. of copper in May. The Batopilas property has operated without interruption and produced for the first two weeks in April 14,600 oz. of silver. The various properties at El Oro have suffered no interruption by reason of the disturbed conditions. El Oro Mining & Railway Co., Ltd., reports a profit of \$62,510 from its operations in the month of April. It is announced that the Shattuck Arizona people have so far progressed with their plans for the erection of a smelter as to purchase some 250 acres of land at Douglas, adjoining the lands occupied by the Copper Queen and Calumet & Arizona smelters, for the erection of their new plant.

The zinc mines in and about Joplin and Webb City, Missouri, and in the Quapaw reservation in Oklahoma, are experiencing a hitherto unknown degree of prosperity. Zinc ores are selling in the neighborhood of \$60, which is about the best previous record.

The copper situation shows no new development beyond a further fractional advance in price to around 16½¢, some sellers of copper even quoting above this figure. It is quite apparent that the producers feel that they have the situation entirely in hand and propose as far as possible to make up for some of the 'hard sledding' which they have had since 1907. Increased dividends are looked for in many instances. Calumet & Hecla, North Butte, Quincy Mining, Old Dominion, Tennessee Copper, and others are expected to increase disbursements. It may be considered certain that dividends will be increased where it can be done. There is much accumulated stock to be distributed to the public, and dividends constitute one of the best inducements to bring the general public into the market.

The Guggenheim interests are said to have taken an option on the Needles group and thirteen adjoining claims in the Miami district, near Globe, Arizona. The New York and London markets are both much interested in the rumored possibilities of the dissolution of Amalgamated Copper and the absorption of its assets by the Anaconda. There has been a great deal of interest in the recent silver market, the price on April 30 being higher than at any time since 1907.

GLOBE, ARIZONA

MIAMI APRIL RECORD.—RECONSTRUCTION OF OLD DOMINION SMELTER.—DEVELOPMENT NOTES.—PROGRESS AT INSPIRATION.

The Miami Copper Co. produced during April, 2,688,790 lb. of copper concentrate. There were mined 83,465 tons of ore, of which about 29,000 tons came from development work, 32,000 from square-setting next to the capping, 14,000 tons from the shrinkage stopes, and 8000 tons from the old dump at No. 2 shaft. Development work for the month amounted to 6602 ft., comprising 4492 ft. of driving and 2110 ft. of raising, virtually all in ore. One churn-drill was in continuous operation exploring the north-eastern part of the property. The erection of the steel tailing-tower is finished and it is being equipped with four 60-ft. bucket-elevators, all of different make, it being intended to make a test of their wearing qualities. In the concentrator, the 100-hp. motors that drive the intermediate

crushing machinery are being replaced by 150-hp. motors, and a small experimental section is being run in connection with the sixth unit. Another water-tube boiler will be added to the power-house equipment, after which both compressors can be run to capacity and furnish air for hoisting, that work being now done by steam generated in the hoist-building. A diamond-drill will soon be rigged up on the 570-ft. level and the ground below that level explored. J. Parke Channing was at the mine recently and has gone to New York by way of Nevada.

The smelter production of the Old Dominion for April was 2,150,000 lb. of copper. The management does not expect to materially increase the production until the milling capacity has been increased. Appropriations have been made for construction work that will involve the expenditure of \$600,000 during the next two years. The work includes the improvement and enlargement of the concentrator to increase its capacity from 500 tons to 1000 tons per day, and the construction of a new crushing and sampling mill, all to be of steel and concrete. H. Kenyon Burch, designer of the Miami, and other large concentrators, will have charge of the work. Changes will also be made whereby ore will be hoisted in skips instead of cages, thereby increasing hoisting capacity. The erection of the new flue and dust-chamber for the converter plant will be started in about ten days. The shaft is being sunk from the 16th to the 18th level. About 1150 men are employed.

The Superior & Boston is shipping ore to the Old Dominion smelter at Globe, but has difficulty in getting enough cars. The ore is all coming from the stope below the sixth level on the Great Eastern vein and local officials say that a carload per day could be shipped if the cars could be obtained. Shipments were started on April 22, and four cars were shipped during that month, the first three averaging 91½% copper and the fourth 71½%. Six cars were shipped during the first two weeks of May upon which smelter returns have not been received. Development continues on the 12th level, where the southeast cross-cut is being advanced, but nothing new of importance is reported.

About 20 men are employed at the Gibson mine, nine miles west of Miami, and ore is being hauled regularly to Miami and shipped to the Old Dominion smelter at Globe. Work is confined to the fourth and fifth levels on the Pasquale vein and all ore mined at present is coming from the fourth level, where five stopes are being worked. Cross-cuts driven a few feet into the hanging wall have disclosed shoots of ore as wide and of as high a copper content as those now being stoped, and stoping will be started on these. The south drift on the fourth level is being advanced and drifts are being driven north and south on the fifth level. Shipments assay from 16 to 18% copper.

High-grade gold-lead ore is being hauled from the Duquesne mine, seven miles northwest of Miami, to the town of Miami, preparatory to shipping to the El Paso smelter. Four men are now employed at the mine and are reported to be mining about ten tons of ore per day. The last shipment assayed about 15% lead and over an ounce per ton in gold, and the present shipment is expected to run even better. The development of the New State mine, seven miles northwest of Miami, is under the supervision of John Shaw. Five men are employed and work is at present confined to sinking the shaft, in which 4 ft. of lead-molybdenum ore was recently found. The shaft is 45 ft. deep, and while the vein is of varying width, the ore is reported to be of better grade as depth is gained.

The development of the Inspiration Consolidated mines is proceeding steadily and the number of men employed is being gradually increased. Shafts No. 1 and 2 at the Live Oak mine are being sunk and preparations are being made to resume sinking at the Scorpion shaft. Ore from development is being extracted through the Joe Bush shaft. The tests on the concentration of the ores, that J. M. Callow has been conducting in the experimental mill for the past five months, are completed and some of the results will probably be made public soon. The survey of the Black Warrior ground for a possible millsite continues.

General Mining News

ALASKA

CORDOVA

The Alaska Consolidated Copper Co., owning the McCarthy properties at the foot of Kuskulana glacier, has sent in A. D. Iles to build a wagon-road from Mile 158 on the C. R. & N. W. railroad.

FAIRBANKS

The Fairbanks Mining & Reduction Co. has been organized to furnish facilities for custom milling on the various creeks near Fairbanks. Batteries of five stamps of standard make will be purchased this season. W. B. Vanderlip is manager. Strong efforts are being made to interest Congress in the building of an automobile road from Chitina to Fairbanks, so as to provide adequately for mail service the year around.

KETCHIKAN

Fourteen additional lights, numerous buoys, and several wireless stations have been authorized, and most of them will be erected in Alaskan waters this summer. Martin Bugge is working eight men at Smugglers Cove and has driven an adit 100 ft. on his property. B. A. Earledey is erecting a 10-stamp mill at the Dolomi.

KOYUKUK

A stampede is on to Hammond creek, a tributary of Koyukuk, a short distance above Coldfoot. It is said that \$30,000 in nuggets was taken from one thawing of three feet on the Hastings ground.

SEWARD

Repairs along the line of the Alaska Northern are being made. The motor car has been running as far as Mile 49 since May 8.

VALDEZ

Members of the Valdez chapter of the American Mining Congress have addressed a letter to the secretary, J. F. Callbreath, at Washington, expressing opposition to leasing Government coal lands. Much satisfaction is taken in the fact that the current appropriation bill at Washington provides for the building of a dike to protect Valdez from floods from the glacier.

ARIZONA

GILA COUNTY

(Special Correspondence.)—The Southwestern Miami has three churn-drills in continuous operation, but none of the holes are yet deep enough to reach the orebody. One churn-drill is working on the Barney group, on hole No. 3, which is 485 ft. deep and in dacite. The large churn-drill on the Schultze group, under option to the South Live Oak Development Co., is running steadily and is drilling a 17½-in. hole, which is now over 100 ft. deep and in the granite porphyry. Lessees at the Black Warrior mine, near Miami, are still shipping copper silicate ore to the El Paso smelter. The shipments have been averaging about 9% copper.

Globe, May 15.

GREENLEE COUNTY

The Kinney bill, providing that only English-speaking workmen may be employed in mines and smelters in Arizona has passed the Senate. The Twin Peaks M. Co. has bought the 10-stamp mill of the North American Copper Co., formerly operating near Lordsburg.

MOHAVE COUNTY

The Frisco Mines & Power Co. is shipping about \$15,000 in bullion each month, working seven men underground. The George Washington mine, at Mineral Park, is putting in machinery and will soon have forty or fifty men at work. Good orebodies running as high as \$80 per ton in gold and silver are being found. Rich ore has been found in the adit of the Nevada-Arizona Mines Co.'s property, at Music Mountain.

PINAL COUNTY

Milling costs for the first quarter of the year at the Ray Consolidated were 56c. per ton, while mining costs were 85c. per ton. During the quarter 301,000 tons was milled, producing 7,125,000 lb. of copper in concentrate. Four units of the mill are now in operation, treating 4100 tons per day, and the fifth unit is expected to start by July 1. Of the shares of the Ray Central M. Co., nearly 97% have been exchanged for Ray Consolidated shares. The smelter at Hayden was blown in last week, but no reports have been given out as yet.

CALIFORNIA

AMADOR COUNTY

(Special Correspondence.)—Sinking on the 1400-ft. shaft of the Keystone has been resumed. It is said it will be sunk 500 to 600 ft. more, in the hope of finding the downward extension of the veins. This property recently passed under the control of the New Keystone Mines Co., composed largely of local and San Francisco people. The new vein recently found in the Central Eureka is said to be nearly 10 ft. wide at the 2800-ft. point. All the ore is of milling grade. The 40-stamp mill is running steadily, and the April clean-up is reported to have yielded about

KEYSTONE MINE.

\$13,000. This leaves net profits of about \$5000. Ore is coming from the 2700 and upper workings. The Bunker Hill paid its regular monthly dividend of 7½c. per share May 15. Conditions at the mine are reported particularly satisfactory, with a large percentage of the tonnage coming from the 1950-ft. level. E. Hampton is superintendent. San Francisco people have resumed work at the Defender. The 300-ft. shaft will be deepened and efforts made to economically treat the large veins of low-grade ore. The property is equipped with a 10-stamp mill. The company plans to employ electric power. It is reported that J. J. McSorley and associates contemplate reopening the Alma mine, within the city limits of Jackson, if sufficient funds can be obtained. The California Exploration Co. has arranged to install two electric pumps at the 1040-ft. point in the shaft of the Plymouth Con. mine at Plymouth. The mine has been unwatered to the 1000-ft. level and the 1040-ft. point will soon be clear. Motors and other equipment have arrived.

Jackson, May 20.

NEVADA COUNTY

It is reported that the Kenosha mine will be reopened by July 15. R. E. Sutherland, the secretary of the company, will move to Grass Valley soon. G. W. Roote will be in charge. J. C. Low and William Gregory have found rich ore in a raise on the Black Bear group, near Moores Flat, some of which assays \$40 per pound.

SIERRA COUNTY

A 3-ft. vein of good ore has been opened in the Bonanza Queen, according to press reports. Rich ore is also being found at the Sixteen-to-One. All the buildings on the North Fork mine near Forest City, were destroyed by fire recently; the loss is estimated at \$3000. C. W. Morse and J. W. Greenbank have taken an option on the Oxford mine, 1½ miles north of Downieville. The directors of the Rio Antigua mine visited the property this week with a view to planning further development. The Kate Hardy

mine has been sold under a deed of trust, and it develops that when J. W. Morrell and W. M. Biggs bought the mine three years ago they borrowed the money to make the purchase and failed to repay it.

TRINITY COUNTY

(Special Correspondence.)—The Craig Mining Co. has purchased 30 stamps from the old Fairview mill and is arranging for their installation at the Mason & Thayer quartz mine near Dedrick. Vigorous development of the Mason & Thayer and Globe properties is projected. An electric-power plant will be erected at Canyon creek. R. K. Clancey is manager. The Trinity River M. Co. has arranged for increased activities at its gravel deposits near Lewiston. The new 11-in. ft. dredge has been practically completed and will go into commission early in June. The electric-power plant is rapidly nearing completion, and an excellent water-supply system has been provided. Eastern people are heavily interested. N. L. Smith is president. The Trinity Hydraulic M. Co. is arranging for resumption of operations. The property has been idle several months, owing, it is said, to the death of a leading stockholder. The holdings embrace 200 acres near Minersville. The property was worked about forty years ago by French capitalists, but recently passed under the control of M. V. Whipple and associates of Minneapolis. M. A. Singer is general manager. Lack of early snow will probably result in shortening the placer season in this county. The late storms have temporarily relieved the situation, but the snows came too late for a long season. La Grange and other large companies have fairly dependable water supplies, but smaller operators are less fortunate. It is reported the Trinity Mining & Reduction Co. is arranging for an increased production at the Headlight mine.

Weaverville, May 19.

TUOLUMNE COUNTY

The mill at the Providence has begun work, and operations have been resumed at the Springfield Tunnel & Development gravel mine. Ten stamps are dropping at the Mammoth mine, Jacksonville. The Van de Weerd mine, near Columbia, has been bonded to Freeman & Watson. Forty stamps are dropping at the Dutch mine, of which C. H. Segerstrom is manager. New compressors and transformers have been installed and 60 men are employed. B. T. Heckman has been arrested for failure to pay the miners in his employ and is endeavoring to effect settlement by offering them oil stock.

W. N. Sledge and others will explore by drilling the old river channel $2\frac{1}{2}$ miles east of Sugar Pine, with a hope of finding rich gravel.

COLORADO

CLEAR CREEK COUNTY

(Special Correspondence.)—Work will be resumed on the Morning Star property on Saxon mountain during the next few days. A 2-ft. body of ore is exposed that mills 55% zinc and 50 oz. silver per ton. E. J. Butts is constructing a cabin and blacksmith shop on a property near Clear lake, on Alpine mountain. An adit is to be driven to intersect a series of veins lately found. Chicago capitalists are interested.

Georgetown, May 17.

(Special Correspondence.)—The shaft-house at the Gem mine on Seaton mountain was destroyed by fire on Saturday, May 11. The loss amounts to \$30,000, with insurance of \$12,000. Lessees at the Gem mine are maintaining heavy shipments. Varney & Co. are sending out four to five carloads of milling ore per month. Von Tilborg & Co. are stoping on a body of \$18 ore that is 11 ft. wide. Shipments are being made to the Newton mill.

Idaho Springs, May 17.

GUNNISON COUNTY

The Blaine M. Co. will resume operation in its mine this summer, and the mill will be repaired. The Hard Cash has been leased and bonded to Denver people. Work will be resumed soon upon the Mountain King properties in Rustler gulch and on the Galena Mountain adit, as well as

at the Doctor mine on Spring creek. The snow still lies heavy in many places, but is rapidly going off.

OURAY COUNTY

An electric zinc concentrator will be built on the site of the Beaumont sampler during the coming summer, according to David Foerster of the American Zinc Ore Separation Co. The Brown Mountain company's smelter is progressing rapidly. T. B. Crawford is general manager and George Lowe will be smelter superintendent. The Senorita at Camp Paquin is shipping ore that runs as high as 100 oz. silver. H. A. Lee is negotiating for the sale of the Slide-Newsboy group of mines at Camp Paquin. Lessees at the Newsboy have been shipping silver ore which runs as high as \$50 per ton. Ed. Arps and others of Ouray have taken a lease on the Frank Hough mine, above Animas Forks. The Boston people, who last year bought the Emma mine in Lee Lake basin, will resume work soon. Ten stamps are at work at the Atlas on ore from development work, and ten more will be started as soon as water enough is available.

TELLER COUNTY (CRIPPLE CREEK)

The Abe Lincoln shaft, in Poverty gulch, has been leased by the Stratton estate to A. Hahnwald. J. L. Nichols has been elected to fill the vacancy on the directorate of the Mary McKinney, left vacant by the death of his father. It is reported that E. A. Colburn has an option on the Mary McKinney and that if it is taken a mill will be constructed embodying the Warwick-Clancy process. The ore-body has been proved on the 1500-ft. level of the Vindicator. A new ore-shoot has been found on the 600-ft. level of the Ajax, south of the shaft. It is $2\frac{1}{2}$ to 3 ft. wide and assays \$30 per ton. The Colburn mill is treating 140 tons per day. The site has been selected for the Gaylord mill and work has started.

IDAHO

IDAHO COUNTY

The 2-stamp mill in the Last Chance, near Elk City, was started last week. The mill is now running on ore taken from development work in the adit in the north vein. The adit is in 260 ft. on the south vein, which is 30 in. wide and yields \$30 per ton. The mine is owned by J. P. Larsen of Elk City and Wilson brothers of Spokane. The Golden Rule placer mine started work early in May; the Golden Seal is already at work. At both properties good clean-ups are expected this season.

SHOSHONE COUNTY

The option on the Idora Hill M. Co. property for \$225,000, held by J. F. Howarth has been allowed to lapse and the owners are planning to work it themselves. The Bunker Hill & Sullivan has ordered a number of first-aid kits, and the miners are being drilled in first-aid work. This company has paid its 176th dividend, a total of \$13,453,950 to date. At the Black Horse mine the winze has reached a depth of 30 ft. and has 3 ft. of ore in the bottom. The Caledonia has purchased new equipment. This company has blocked out a large supply of ore and the stopes and dump are asserted to carry 15 to 40% lead and 40 oz. silver per ton. Charles McKinnis is manager.

A new pump has been put in place at the Nellie, and one shift is at work under Jack Alger and Cap Horton, the owners. The Jack Waite lower adit has reached a point within 100 ft. of the vein. The Kniekerbocker is about to commence regular shipments. Work has begun on the project for hydro-electric development at Thompson's falls, and the auxiliary plant at Prospect creek is already under construction.

MONTANA

SILVERBOW COUNTY

The Tuolumne company will double its output this month, and next month will do even better than that. For several months past the company has been shipping 150 tons per day, but during the first week of this month the output was increased and is now averaging 300 tons per day. The new Gagnon four-compartment shaft has been completed to a depth of 2200 ft. When shaft-sinking was going on, sta-

tions were not cut on the various levels. This work is now in progress and will require two months. As all the ore of the Gagnon mine is hoisted through the Original shaft, this new shaft will be maintained only for ventilating purposes. Shaft sinking in the Pilot Butte is going on at the rate of 85 ft. per month, and a depth of 1080 ft. has now been reached. The mines of the Anaconda Copper Mining Co. produced 384,070.20 tons of ore and 4602.61 tons of concentrate during the past year, making a total of 3,848,672.81 tons.

LINCOLN COUNTY

At the Shaughnessy group of claims it is reported that 10 ft. of clean shipping ore has been found.

NEVADA

HUMBOLDT COUNTY

(Special Correspondence.)—The Seven Troughs Coalition Co. is developing several small shoots of quartz. A 12-in. shoot of \$60 ore is reported in the west drift. It is understood the company has earned good profits for the first four months of 1912. D. R. Dwyer, of Seattle, has purchased the Hanks lease on Charleston Hill estate, National district. Twenty-five tons of concentrate from the National Mines plant was recently shipped to Winnemucca. The product came from the old Stahl lease dump, estimated to contain 3000 tons of ore averaging \$80 per ton. This is at present being crushed by the National mill. The National mines have paid dividends of \$570,000 to date. R. M. Edmonds has purchased the holdings of W. Critchfield, and states active work will soon start.

Winnemucca, May 18.

LYON COUNTY

It is reported that the second furnace at the smelter at Thompson will have a length of 30 ft. The furnace now in operation has a length of 25 ft. and is smelting about 700 tons per day. Receipts of ore at the smelter for the week ended May 9 were 2662 tons from the Nevada Douglas, 1954 tons from the Mason Valley, and 562 tons of custom ore. The Yerington Malachite is shipping 30 tons of ore daily to the furnace. The annual meeting of the Nevada Douglas was held at Salt Lake City May 15. During the year ended April 1 the company was producing only part of the time, but yielded 2,385,000 lb. of copper, the net earnings being \$79,930.

The average of the ores shipped from the Ludwig property was 5.62% copper; from the Douglas Hill, 5.24%, and from the Copper Basin, 5.06%. The ore reserves of the property, as reported at the meeting, now total 869,000 tons, divided as follows: Ludwig, 469,000 tons; Douglas Hill, 350,000; Copper Basin, 50,000 tons. The gypsum deposit is valued at \$750,000, while the half interest in the Nevada Copper Belt Railroad Co. is valued at \$500,000. The auditor's report shows a first mortgage bonded indebtedness of \$600,000, \$100,000 in convertible notes and \$93,530 in current items, to offset which are due on settlements for ore \$61,001 and notes receivable for \$40,342.

An interesting development at the meeting was the appointment of a special committee of directors to investigate the feasibility of the Nevada Douglas company erecting its own smelting plant at the expiration of the present contract with the Mason Valley company. Another committee of directors was appointed to investigate the question of erecting a milling plant to treat the gypsum deposit of the property.

WHITE PINE COUNTY

(Special Correspondence.)—A record run was recently made from the steam-shovel pits of the Nevada Consolidated mines, when 14,168 tons of ore was taken out in a single day; 253 cars transported the ore to the smelter at McGill. A daily average production of over 10,000 tons is being maintained, and the plant is running at full capacity. The Veteran mine is contributing 1100 tons per day to the total output. On the 400-ft. level workings the ore recently uncovered is said to average 4 to 10% copper. A small flow of water has developed near this point, and a pump has been installed. Five steam-shovels are work-

ing. The Coppermines company reports the discovery of a new body of ore, samples assaying about 10% copper. It is reported the Nevada Northern railway may build a spur track from its road to the mines to facilitate shipments. Shipments of lead ore from the Lead King and Ely Gibraltar mines have commenced. The product is going forward to Salt Lake smelting plants. The ore is estimated to average nearly 70% lead, with some silver. It is rumored the Ely Central has found sulphide ore of workable grade in a churn-drill hole on its Chispy claim.

COPPER FLAT, ELY.

The claim lies south of Copper Flat, but is largely in the rhyolite.

Ely, May 17.

The Nevada Copper Co. produced 6,116,000 lb. of copper during April. The company has made arrangements to pump water from the Zack shaft of the Ely Central for the steam-shovels and locomotives and 250,000 gal. per day will be secured.

OREGON

BAKER COUNTY

The new electrically-operated mill at the Highland gold mine, near Haines, is treating 50 tons per day. The Three Links group on Trail creek has been bonded for \$20,000 to a group of mining men. H. R. Barr has sold his one-fourth interest in the Eureka Dei Gratia group on Granite Boulder creek, near Greenhorn, to S. F. Brauson.

JOSEPHINE COUNTY

John Carlson, George Colvin, and Oscar Shattuck have found rich free-milling quartz on the old Victor mine, which was formerly owned by Sanders Brothers, having taken out about \$900 in five days. The Minnehaha Gold Hydraulic & Dredge Co. has sold its first issue of shares and will install a \$50,000 dredge on its property at Tyhee bar, on Rogue river, a mile below Whiskey creek. Erection of a 500-ton mill at the Alameda copper mine, on Elk creek, is contemplated. A 100-ton concentrator will be erected by the Three Lodes, which has taken in the Golden Pheasant property on Galice creek. The concentrates, which assay as high as 12% copper, \$5 to \$28 in gold, and 11 oz. platinum per ton, will be shipped to Sweden for treatment.

TEXAS

BREWSTER COUNTY

(Special Correspondence.)—Two of the recent discoveries of gold and silver in the vicinity of Alpine are within the town limits. One outcrop of silver and gold ore that was found at the edge of the city is being explored with splendid results. An assay of the ore shows 1101 oz. of silver and 3.52 oz. of gold per ton. This is causing much prospecting to be done upon other properties near the town. On the opposite side of town from this discovery, another vein is being exploited. In the mountains about four miles from Alpine a recently located claim is being developed with good results.

Alpine, May 15.

UTAH

TOOELE COUNTY

Work will soon be under way for the construction of a

third blast-furnace at the Tooele plant of the International S. & R. Co. A subsidiary company known as the International Lead Refining Co. and capitalized at \$500,000, will be organized to take over the lead refinery now under construction in Indiana. The shares of the Utah Metal Mining Co., which is tunneling the divide between Bingham and Tooele, were listed on the Boston Curb recently. The tunnel is 11,000 ft. long, and 2400 ft. still remains to be driven.

WASHINGTON

SPOKANE COUNTY

Graham B. Dennis, chairman of the Spokane section of the American Mining Congress, has appointed W. J. Nichols, J. H. Tilsley, and W. J. Harris as a committee to raise \$10,000 for the convention of the American Mining Congress in Spokane next November. The Spokane Chamber of Commerce guaranteed \$5000 to the congress, and it is the intention of the local section to use any funds in excess of that amount in providing excursions to adjacent mining districts. One of the jaunts will be to the Coeur d'Alene. From there the special train will run to Republic by way of Spokane.

CANADA

BRITISH COLUMBIA

(Special Correspondence.)—Railway building in British Columbia is active. On Tuesday, May 14, Louis W. Hill, president of the Great Northern railway, with C. R. Grave (who soon is to succeed to the presidency), H. J. Jackson, general passenger department, and M. J. Cortello, railway contractor of St. Paul, drove into Merritt from Penticton by automobile in ten hours, the total distance of 155 miles of British Columbia mountain roads. The party left the next day for Vancouver, where work will be commenced immediately on the construction of the V. V. & E. railway terminal. The Great Northern railway is now pushing construction over the Hope mountains from the Tulameen valley to the coast. The Kettle Valley railway (C. P. R.) is also racing with the Great Northern in building into the Similkameen for a share of tonnage from this rich mineral district. Mining is being stimulated by this railway building. The B. C. Copper Co. has taken up the bond on the Voight group of 62 claims on Copper mountain, having opened up a large deposit of self-fluxing ore. Mr. Campbell, of the Granby company, is in the Similkameen examining copper properties with a view to bonding. J. R. Leekie has taken a working option on the United Empire group of claims near Princeton for the Crown Reserve company of Cobalt. Mr. Turnbull is examining properties in the Similkameen with a view to bonding for the Consolidated M. & S. Co. of Trail, B. C. A number of properties in Camp Hedley are being developed by American capital. The Hedley M. Co. continues to pay regular quarterly dividends of 25% on a capitalization of \$1,200,000. M. K. Rodgers is developing the Oregon group. A rich gypsum deposit is being developed near Granite creek. The platinum gravels of the Tulameen river will be developed this summer by four different companies. Coal mining in the Nicola valley is picking up again and coke-ovens are to be erected by the Nicola Valley Coal & Coke Co. The Diamond Vale collieries have not been opened since the big gas explosion and disaster in which five men lost their lives on March 7. Merritt, May 15.

The Standard Silver-Lead Mining Co. of Spokane, operating a shipping property in the Slocan district, has just paid its second dividend, the amount disbursed being \$50,000. Dividend No. 1, of \$25,000, was paid April 10. Charles Hussey, secretary-treasurer, announces that the company expects to pay regular monthly dividends from now on. These officers were elected at the annual meeting: president, W. J. C. Wakefield; vice-president, John A. Finch; general manager, George H. Aylard; secretary-treasurer, Charles Hussey. Patrick Clark and the officers constitute the board of directors. It is announced there will be no change in the company's general policy. The mine is in

excellent condition, and development is to continue as during the last several months.

WHITE HORSE

The railway spur to the copper mines near here is being repaired and 45 men are at work at the mines.

YUKON

A pay-streak 200 to 300 ft. wide, 1 to 5 ft. deep, and averaging \$1 per yard, is reported on the Harry Iseman property at the mouth of Hunker creek. The Canadian-Klondyke Company expected to start its big dredge about May 1, on which date also the Klondike Mines Railway was planning to resume service. The first train should run through to Dome by May 20. The Northern Navigation Co. has arranged to dispatch five more boats from Dawson this season than last. The first boat of the season scheduled to leave St. Michaels is the *M. L. Washburn*, which is to sail June 18. Plans are being made for a Yukon Exposition at Dawson August 14 to 17.

COLOMBIA

The department of public works has issued a circular calling attention to the fact that foreigners have the same right to acquire mines as Colombians, and that all that is necessary is to comply with the provisions of the mining code. Free instruction in mining is provided at the school of mines at Medellin.

MEXICO

SONORA

April shipments of ore and bullion, by properties in this state, passing through Agua Prieta, were as follows, as shown by the report of the Collector of Customs at that place.

Property.	Cars.	Tons.
Moetzuma Consolidated	250	10,696
El Tigre	8	359
Churunibabi	30	966
San Pablo	1	19
Good Enough	1	33
Tijera	1	30
La Fortuna	1	29
Bellota	1	31
Caridad	1	22
Los Metates	1	8
Vaquero	2	15
Noria	1	15
La Piedad	1	5
Totals	299	12,264

High-grade and bullion: Gueriguito, 28 sacks, 2081 lb.; Los Tajos, 2 bars bullion, 85 lb., 14 sacks ore, 1386 lb.; Batue, 2 sacks ore, 238 lb.; Luz Roja, 40 sacks, 3916 lb.; El Tigre, 56 bars, 5005 pounds.

The total value of all shipments of ore is as follows:

Copper	\$741,900
Silver	369,200
Gold	127,700

\$1,238,800

NICARAGUA

(Special Correspondence.)—In the Matagalpa district, F. W. Nols, formerly manager of the Babilonia mines of the Arroya Limited, has been appointed general manager of all the Arroya properties in Nicaragua, with headquarters at Matagalpa. George Fairbairn, manager of the Santa Francisca mine, has resigned and accepted the position of superintendent of the Babilonia mine of the Arroya Limited, of which H. W. Coe is manager. Considerable activity in this district may be expected once the financial tangle is settled. The first loan of \$1,500,000 to reform the currency has been authorized in the *Asamblea*, and the national bank will now be established. The new monetary unit will probably be the 'cordoba', equivalent to \$1 U. S. currency, but this has not been definitely settled as yet.

Personal

Professional men are invited to send news of their engagements and travels. Such news is interesting to friends.

J. W. ABBOTT is here.

A. C. VEATCH is at the Palace.

EDMUND JUESSEN is in Nevada.

P. BOUERY is at the St. Francis.

T. H. LEGGETT is in San Francisco.

JAMES T. WALL is in San Francisco.

JOHN B. FARISH is in San Francisco.

LOUIS A. WRIGHT was here during the week.

J. E. SPURR visited the Mother Lode recently.

CHARLES JANIN will leave for Nome, June 1.

F. C. NEWTON will go to New York next week.

FREDERICK G. CLAPP has gone to western Canada.

J. F. NEWSOM will leave for Alaska during the week.

VICTOR BARNDT was in San Francisco during the week.

H. F. LEFEVRE has gone to Honduras, returning in July.

THOMAS T. READ has gone to Jackson and Amador City.

H. S. CHAPMAN is now at Arroroy, Masbate, Philippine Islands.

E. H. SIMONDS has gone to Alaska on professional business.

R. B. STANFORD has gone to Honduras, to be absent for six weeks.

R. P. McLAUGHLIN has returned from Plumas county, Nevada.

A. W. ALLEN has joined FRANCIS DRAKE at Bulawayo, Rhodesia.

F. C. DEVEREUX has returned to Minneapolis from Durango, Mexico.

W. H. LANDERS has gone to Inyo and Mono counties on professional business.

J. J. STEVENSON's address will hereafter be 215 West 101st street, New York.

C. T. NICHOLSON has returned from Burma and will go to Dawson in a few days.

A. P. FLAGLER was at Nevada City recently, and has gone to Palm Beach, Florida.

GELASIO CAETANI will go to the Bunker Hill & Sullivan mine at Kellogg, Idaho, next Wednesday.

J. P. CHANNING was in San Francisco during the week and has gone to Oroville, on his way to New York.

D. M. FOLSOM has accepted a position on the editorial staff of the *Mining and Scientific Press* for the summer.

ARTHUR FEUST has resigned as superintendent of the Esmeralda mine and is now in general consulting practice in Nicaragua.

ROSS B. HOFFMANN is in charge of field operations for the Pioneer Company of Siberia, Ltd., and left London for Nikolaievsk this week.

Obituary

O. H. PACKER died at his home in Berkeley, California, on May 14. He had long been engaged in mining in California and was well known on the Pacific Coast.

DONALD M. SCOTT died at Laurium, Michigan, April 29. He was born in England, went to the Lake Superior country some fifteen years ago, and was employed by several of the large copper mines.

Market Reports

LOCAL METAL PRICES

San Francisco May 23.

Antimony	11-11½c	Quicksilver (flask)	42
Electrolytic Copper	16½-16¾c	Tin	50-51½c
Pig Lead	4.15-5.40c	Spelter	7½-7¾c
Zinc dust, 1400 lb. casks, per 100 lb., small lots \$9.50-9.75; large \$7.50-8.50			

METAL PRICES

(By wire from New York.)

NEW YORK, May 23.—Attention of metal dealers has been mainly centred this week on copper, which was in strong demand. A large business was done both for the home trade and for export. Lead was quiet this week. The demand for spelter has lessened and the market was lifeless. Average daily prices for the past week, in cents per pound, based on wholesale transactions, standard brands, are given below.

Date.	Electrolytic Copper.	Lead.	Spelter.	Silver, per oz.
May 16.....	16.03	4.20	6.70	61½

Company Reports

NEVADA HILLS MINING COMPANY

This company, operating at Fairview, Nevada, has an authorized capital of 1,250,000 shares of \$5 each, of which 1,065,051 shares have been issued. Construction of the company mill was started in the autumn of 1910, was completed and operation of the mill started September 12, 1911, and closed down on January 13, 1912, on account of lack of hydro-electric power. The operations for the year ended March 31, 1912, during which the mill ran four months, are summarized below. The mill resumed operation April 15, 1912. During the four months of operation, ore from cleaning out old stopes was used, of a character unsuitable for the highest recovery, with the result that the operating cost was abnormally high and the recovery abnormally low. The earnings for the year were \$249,873, and the operating expenses \$184,235, leaving an operating profit of \$65,638. The sum of \$48,000 was charged off as depreciation on plant and property, and depreciation was charged off upon the mine at the rate of \$42.67 per ton of ore extracted in order to make the accounts comply with the requirements of the Federal income tax assessors. It should be noted that the ore treated during the year averaged \$27 per ton, and the unit \$42.67 represents the estimated cost per ton to the company of its whole estimated tonnage. An indebtedness of \$495,000 was incurred, but it is hoped to repay this quickly from the profits accruing from regular operation.

LA ROSE CONSOLIDATED MINES CO.

This company, organized under the laws of the state of Maine, has an authorized capital of 1,500,000 shares of \$5 each, of which 1,498,627 have been issued. The assets of the company consist of the entire capital stock of the La Rose Mines, Ltd., the Lawson Mines, Ltd., and the Violet Mining Co., valued at \$7,474,990, and 7262 shares of Uni-

versity Mines, Ltd., valued at \$18,145. The income of the company for the year ended December 31, 1911, was \$627,000 received as dividends on 6,000,000 shares of La Rose Mines, Ltd. Of this \$599,450 was paid out in dividends of the La Rose Con. Mines Co. and \$33,319 expended on administration, thus cutting down the surplus of the holding company to \$7591. This company is merely a holding company and has no physical assets. Of the companies of which the shares are held, only the La Rose Mines, Ltd., is a source of profit. No work was done on the University Mines during the year, and in the Violet mine only a small amount of exploratory work was done, without finding ore. The Lawson mine produced 1,221,000 oz. of silver during the year, but the profit from this mine is not separated from that of the La Rose in the accounts. Some details of operation follow. Shipments during the year amounted to 3561.4 tons, containing 4,092,709 oz. of silver, of a net value of \$2,014,391, or \$441 per ton. The average price received for silver was 53.55c. per ounce. The freight charges amounted to 2% of the gross content of the ore, treatment 1.32%, and smelter deduction on silver 5.14%, sampling, assaying, and other charges 1.04%, a total of 9.5%. In the concentrating plant a recovery of 75.4% is made on a concentration of 32 tons into 1; 36,264 tons having been milled. The cost of milling is given as \$3.02 per ton of ore milled.

DOBIE MINES, LIMITED

This company has an authorized capital of 300,600 shares of \$5 each, of which 240,000 have been issued, and owns three patented claims, purchased from the Tisdale Mining Co. The report of George E. Farish, the general manager, for the year ended March 31, 1912, concludes as follows:

"It will be noted that upon the 60-ft. level, as shown in the incline raise, the vein has an average width of 2.5 ft., with an average value of \$3.94 over a length of 33 ft. On the 90-ft. level, while the hanging wall is well defined, the vein is narrow, and at no point over a length of 151 ft. does the most careful sampling and panning disclose profitable ore. * * * Though this vein may widen, forming mineralized lenses both along the strike and dip, and though it is also true that other lenses may occur along possible fracture planes in the more schisted area encountered in the north cross-cut at the 90-ft. level, there is nothing to indicate that they will be of commercial size or value. From the development done and a careful consideration of the conditions here presented, I consider that the prospects of finding ore-shoots of sufficient size and value to make this a paying property are not encouraging enough to warrant further expenditures, and I have therefore recommended that the property be closed down. While it is possible that development upon the adjoining properties may at some future date make it advisable to further prospect the ground, there is nothing at this time to warrant further expenditure upon the property."

The balance sheet of the mine office books is as follows:

ASSETS AND EXPENDITURES

Properties	\$1,073,500.18
Buildings	4,153.97
Plant and equipment	9,619.83
Fuel	1,920.04
General supplies	938.49
Boarding-house supplies	594.45
Accounts receivable	25.25
Cash in bank	2,424.59
Development	46,130.59
Roads	723.17
Expense accounts	12,069.44
	\$1,152,100.00

LIABILITIES AND RECEIPTS

Montreal Office—Current acct. (remittances to mine office)	\$ 52,100.00
Montreal Office—Special acct. (property account)	1,100,000.00
	\$1,152,100.00

Book Reviews

Any of the books noticed in these columns are for sale by, or can be procured from, the MINING AND SCIENTIFIC PRESS.

TREATISE ON HYDRAULICS. By Mansfield Merriman. Pp. 565. John Wiley & Sons, New York, 1912. For sale by the *Mining and Scientific Press*. Price \$4.

This is the ninth edition of a standard work, revised and reset with the assistance of Thaddeus Merriman. The eighth edition was published in May 1903. Much new matter will be found on hydraulic instruments, methods of measuring water, oblique weirs, submerged tubes, regulating devices for pipes, conduits, dams, backwater, rainfall, evaporation, and run-off, bringing the subject matter up to present-day practice in hydraulics. The tables of coefficients for orifices, weirs, pipes, conduits, and channels have been revised and extended to embody the results of recent experiments. A new and simplified method of designating numerals has been employed, facilitating ready reference to formulæ discussed in the subject matter. A thorough subject index has been included, and the book is in every way up to the standard that has made nine editions and many reprints necessary since its first appearance in February 1899.

CENTRIFUGAL PUMPING MACHINERY. By Carl George de Laval. Pp. 180, index. McGraw-Hill Book Co., New York, 1912. For sale by the *Mining and Scientific Press*. Price \$3.

The author's preface remarks that "A writer upon centrifugal pumps has said that they defy the mathematician and possess more tricks than a circus mule." The reference to the mule is a particularly apt simile as applied to a centrifugal pump, as, with all its idiosyncrasies and occasional defiance of all known rules, it fills a function in the world's work for which there is no adequate substitute. Mr. de Laval is general manager for the Henry R. Worthington Co., and as such has had an exceptional opportunity for the compilation of a vast amount of data taken from the actual performance of centrifugal pumps under all sorts of conditions, and, aided by a trained mind and a thorough grasp of the subject, he has brought together the result of many years' experience for the benefit of investigators in the same field. Design, operation, and the factors bearing upon them, as well as the limitation of the adaptability of this style of pump, have been treated exhaustively. In fact, the thoroughness and practicability of this book make it infinitely more valuable than any mere discussion of abstract theory, however learned. In addition, Mr. de Laval has exhaustively discussed, analyzed, and correlated the theory and practice in such a way as to clear away much of the fog that hangs over this subject, and proves that, after all, it is indeed an obstinate pump that can long continue to "defy the mathematician."

TEXT BOOK OF CYANIDE PRACTICE. By H. W. MacFarren. Pp. 291. Ill., index. McGraw-Hill Book Co., New York, 1912. For sale by the *Mining and Scientific Press*. Price \$3.

This book covers both the principles and practice of cyanidation, though no attempt is made to describe the treatment at individual mills. It is an excellent general statement; simple, accurate, and well written. Following chapters devoted to history and chemistry of the process, the usual steps in practice, including percolation, agitation, decantation, filtration, precipitation, cleaning-up, etc., are described in detail. The information is fresh and generally accurate, though we do not believe that investigation of the relative efficiencies of various machines has been thorough enough to warrant some of the statements made. Many excellent devices have been perfected and patented for use in cyanidation, but the range of use for most of them is still largely undetermined and their relative value is a factor for determination in each particular situation.

Mr. MacFarren is sound in his discrimination between slime and sand, reserving the latter for crystalline particles no matter how fine, and his discussion of slime treatment is one of the best things in the book. Another excellent feature is a bibliography of cyanidation, much the most complete that we have seen. The book closes with a series of conversion and mensuration tables that adds greatly to its usefulness. Several chapters will warrant expansion when a second edition of the book becomes necessary, but Mr. MacFarren has given an excellent epitome of cyanidation as it now is.

THE ELEMENTS OF STRUCTURES. By George A. Hool. Pp. 182, index. McGraw-Hill Book Co., New York, 1912. For sale by the *Mining and Scientific Press*. Price \$1.75.

This is the first of a series of books on engineering subjects prepared for students in the University Extension correspondence courses conducted by the University of Wisconsin, at which the author is assistant professor of structural engineering, and deals with the fundamentals of structural engineering in a clear and lucid manner that bespeaks a comprehensive grasp of the subject as well as the ability to impart knowledge to others. The book is prepared for those men who, having an ordinary knowledge of arithmetic, algebra, plane and solid geometry, logarithms, trigonometry, mechanical drawing, and strength of materials, are desirous of continuing their studies on engineering construction. Until the advent of the various excellent correspondence schools, the young man who was ambitious to obtain an education along engineering lines, and was unable to avail himself of a regular university training, had no means of study available other than such books as were prepared for engineers and advanced students. These were so technical as to do little more than confuse and discourage the seeker after knowledge and make his ambition to better his condition seem impossible of accomplishment. Such books as Mr. Hool has given us afford an opportunity for any man possessing a rudimentary education plus a goodly amount of application and ambition, to overcome the lack of a university training and qualify himself to enter the engineering profession.

POWER HOUSE DESIGN. By John F. C. Snell. Longmans, Green & Co., London. Pp. 448, index. For sale by the *Mining and Scientific Press*. Price \$6.

The title to this book is somewhat misleading, from an American standpoint, as the proper assembling of apparatus, and the factors governing its selection, installation, and use, form the dominating feature of the subject matter rather than the buildings in which they are enclosed. Practice in many localities is covered thoroughly and comprehensively. Systems, preliminary notes on the choice of site and type of plant, buildings, steam-raising plant, steam and feed-pipe systems, steam generators, various types of condensers, cooling towers, and auxiliaries, internal combustion engines, gas and oil engines, producers, waste-heat stations, hydro-electric power-houses, power-house switchgear, practical notes on electrical plants, small power-houses and substations, form the titles of the chapters into which the book is subdivided, and there are appendices covering water-tube boilers, velocities in circulating water-pipes, British electricity regulations for factories, chimney cooling towers, and tests of feed pumps. These show the comprehensiveness of the text and the variety of types of power-plant installations covered. Seventeen plates illustrating typical power-plants in various parts of the world afford an excellent opportunity for the engineer to study the characteristics in practice both at home and abroad. Many formulae and much statistical data on performance and operation are presented; in fact, the book is practically an encyclopedia on power-plant design and construction, and the absence of superfluous padding greatly enhances its value as a book of reference and facilitates ready reference to the subject upon which information is desired.

Concentrates

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

RELOCATION by the original locator of a claim or any part of it within three years of his failure to perform development work as required by United States statutes, is forbidden by the California statute.

CHEMICAL mixtures—the so-called ‘unknowns’ of the teachers of chemistry—of predetermined composition can now be obtained from some of the principal dealers in chemicals, accompanied by an accurate analysis, and the labor of preparing and analyzing such mixtures is thereby saved.

RIPARIAN rights exist in Montana and are recognized. An appropriation is made by posting a notice in writing at a conspicuous place at the intended point of diversion, stating amount claimed, purpose of appropriation, place of intended use, means of diversion, date of appropriation, and name of appropriator. Within twenty days file with the county clerk a notice of appropriation containing in addition the name or a description of the stream, description of the point of diversion, and reference to a natural object or permanent monument. Notice must be verified as an affidavit. Work must be commenced within forty days of posting notice and must be conducted with reasonable diligence to completion.

BONUS systems of payment are of great advantage where speed is important. At the Laramie tunnel in Colorado the system finally adopted was as follows: When the rate of driving for any calendar month exceeded 400 ft. and was less than 500 ft., each underground employee was paid \$10 extra; between 500 and 600 ft., the bonus was \$15; and between 600 and 700 ft., \$20. This bonus should have been paid to the men in currency, so as to distinguish it from the earnings under the wage schedule, but as this was impracticable, money earned under the bonus was paid with a separate check, thus giving the men a better opportunity to realize what speed meant to them as well as to the contractor.

MONAZITE and zircon are minerals containing rare-earth metals, whose property of becoming incandescent when heated render them valuable in certain forms of gas and electric lights. Monazite is employed in the manufacture of incandescent gas-light mantles of the Welsbach type, and the oxide obtained from zircon enters into the composition of the glow of the Nernst electric light. Both minerals are found in the United States and have been produced to a considerable extent. During 1911, according to the U. S. Geological Survey, no monazite was marketed, although 13,132 lb. of crude sand or ‘ore’ is reported as mined in North Carolina and South Carolina. Zircon was produced in 1911 to the amount of 3208 lb., valued at \$802.

WISCONSIN, New Jersey, and Nevada are the only states in which a heating value requirement for gas has been made by the state authorities. By the ruling of the state commissions, the monthly average ‘gross’ heating value demanded in the first two is 600 b.t.u. per cubic foot of gas, with a minimum value of 550 b.t.u. allowed; in the last named the values specified are 550 and 500, respectively. The public-service commission of the second district of New York has urged such amendments to the state law as will allow the desired thermal requirements to be made by the commission. They are already making extended tests in co-operation with the companies of their district to determine the desirable standards to establish. The public-service commission of Maryland is not yet prepared to establish a requirement as to heating value for the entire state.

Commercial Paragraphs

EDGAR ALLEN & CO., LIMITED, manufacturers of tool steel have moved their Chicago office to 718 West Lake street.

BUCYRUS COMPANY announces the opening of an office at No. 1250 Brown-Marx building, Birmingham, Alabama, under the management of E. L. Byron.

THE ROBINS CONVEYING BELT CO. has secured a contract for the installation of its ore-handling system at the plants of the C. & A. Co. and the Arizona Copper Co. at Clifton, Arizona.

The Smuggler-Union Mining Co., of Telluride, Colorado, has lately installed two 6-ft. HARDINGE pebble mills. The Tomboy Gold Mines, Ltd., of Telluride, Colorado, will also install two 6-ft. HARDINGE pebble mills.

J. T. B. BOGARDUS, president of the ABENDROTH & ROOT MANUFACTURING CO., builders of Root water-tube boilers and Root spiral riveted pipe, has returned from an extended trip abroad in the interests of the export business of his company.

J. W. STONEHOUSE, Victor, Colorado, has placed on the market an indestructible enameled-steel mine bell signal, which has considerable merit. These signals consist of white letters on a blue background and are enameled on both sides, so that they will not rust or be affected by mine waters.

THE SAMSON MANUFACTURING CO., of Denver, Colorado, wish to announce that it has sold to P. E. GARRETSON and associates, the Samson Manufacturing Co., together with the good will, all rights, title, interest, and patents in the Samson rock-crusher. The business under the new management will be carried on under the same name. The new owners have for some time been manufacturing the National pulverizer and are now extending their business in the mining field.

WILLIAM L. RICKARD and CLIFFORD A. SLOAN announce the organization of an advertising company which will conduct its business under the corporation name of RICKARD & SLOAN. The offices of the company are in the Evening Post building, 20 Vesey street, New York. Particular attention will be given to the planning and management of advertising campaigns for concerns engaged in the manufacture of mechanical and electrical apparatus and accessories. The service of the company will include the writing and placing of advertising in trade and other periodicals, and the production and distribution of bulletins, catalogues, and circulars.

After a careful study of the possibility of cyaniding the refractory ores of the Republic district, the OLIVER CONTINUOUS FILTER CO. made an initial installation, under a positive guarantee of successful work. The work done has exceeded the expectations both of the engineers of the operating companies and of the Oliver Continuous Filter Co. Recent sales in this district include the following: Rathfon Reduction Works, North Washington Power & Reduction Co., San Poil Mining Co., and the British Columbia Copper Co. It is claimed that all the filters in the states of Washington, Oregon, and California are Oliver's and that 90% of the filters in Nevada are of the same make.

The executive offices and New York showrooms of the H. W. JOHNS-MANVILLE CO., manufacturers of asbestos, magnesia, and electrical supplies, were moved on April 20 to the new 12-story H. W. Johns-Manville building, Madison avenue and Forty-first street, New York City, from the old quarters at 100 William street, where the company has been for the past fifteen years. Increased business interests in this and other parts of the country have necessitated the move. The large floor area and spacious rooms in the new building will enable a much larger and more complete stock of goods being carried on hand than heretofore, and will also permit of a better supervision over the company's long chain of branch offices, warehouses, stores, and factories scattered throughout the United States

and Canada. This change marks the fifty-fourth anniversary of the company.

What is claimed as the largest order for motor trucks placed with one organization has just been given the INTERNATIONAL MOTOR CO., manufacturers of the Mack, Saurer, and Hewitt trucks, by the Star Motor Delivery Co. and the City Fuel Co. of Chicago. The Star Motor Delivery Co. of Chicago, which is perhaps the largest organization yet formed for general public trucking and transportation service in this country, has just placed an order with the International Motor Co. for 50 Mack trucks of various sizes which are to be put in service within the next few months for handling urban and suburban delivery service of Chicago merchants. This order was placed after months of the most searching investigation and rigid tests of practically every American make of motor truck, and the fact that the Mack was finally selected as the machine best adapted for the severity of the conditions is a distinct triumph for the manufacturers of this oldest of American-made trucks.

The order of the City Fuel Co. for 25 Saurer trucks is the largest single order ever placed by a coal merchant for motor transportation, and comes as a flattering endorsement of the motor truck by an industry which has been, perhaps, one of the most reluctant to be converted to the advantage of motor transportation up to the present time. The first 15 of the Saurer trucks to go into service for the City Fuel Co. will displace 70 double teams, and it is said that before deciding to motorize the delivery department, the City Fuel Co. investigated, tested, and had demonstrated every motor truck of any consequence on the market. In making a test and study of motor trucks for over two years and putting in an investment that means the scrapping of many thousands of dollars worth of existing horse-truck equipment, the City Fuel Co. has pointed the way for hundreds of coal dealers to solve one of their most growing problems—the expeditious, economical, and efficient delivery of coal over a rapidly increasing area which the growth of all large centres has brought about. The City Fuel Co. will use its Saurer trucks in the 'Loop' district of Chicago. The 25 Saurers will displace 100 horses and 25 wagons.

Securing Good Castings for Dodge Products

The Dodge Manufacturing Co., Mishawaka, Indiana, recognizing the fact that the utmost care should be taken in securing the strength of its transmission appliances, maintains a well equipped chemical laboratory. In this laboratory all the various raw materials are analyzed, particularly the pig iron used in the foundry. The composition of the iron is carefully ascertained before it goes into the cupola, and none but the best procurable is used. Although the purchases are made on a guarantee of chemical constituents, each car on being unloaded is sampled for analysis, and the iron remains unused until the report from the company's own chemist shows the exact elements of which it is composed. Some mixtures are high in silicon for soft special castings; some are low in silicon and high in manganese for harder castings. Each mixture, however, is properly proportioned for the work it eventually has to perform.

In charging the cupola, the iron is carefully weighed in the yard, a scale car with a box on it passing from pile to pile of pig iron and getting portions from one pile or another, as the case may demand, to make the proper mixture. These boxes are then hoisted to the charging-floor by an electric crane and are stacked ready for use in the charging-room.

To insure the results in Dodge products, after all care is taken with the composition of raw materials going into the cupola, test bars are taken from the metal coming out, and the final answer to these elaborate preparations is secured. Bars testing 1800 lb. tensile strength to the square inch are considered good by the average foundry, but no metal is considered right for Dodge products unless the test bars show 2200 pounds.

EDITORIAL

MEXICAN conditions have greatly improved in the last two weeks, and there is now a general feeling that the worst is over. Re-establishment of order throughout the country will necessarily be slow, but defeat of the rebels by the Federal forces in Chihuahua is a long step toward peace.

MANGANESE silver ores have given cyanide experts much trouble and they have but rarely been treated with any degree of satisfaction. We are therefore especially glad to print the full details of a study of these ores, made by Mr. Will H. Coghill in the metallurgical laboratory of Northwestern University. The first of the series of articles appears this week.

PHYSIOGRAPHY is a fascinating science. It was a surprisingly long time before geologists turned their attention from the study of sediments to the question of what was happening on the land while various beds were being laid down in the sea. Just how practical such studies may become is excellently illustrated in Mr. J. B. Tyrrell's study of pay-streaks in placers, noted elsewhere.

CAPITALISTS in search of a large and profitable business have recently been offered the opportunity to join a large international limited liability undertaking for the purpose of working various precious ores. The success of the enterprise, which is Russian in inception, is "guaranteed" by "new methods of extraction without losses." The receiver of the enticing literature circulated by the promoters is informed that such losses "till now amount to 100 per cent or more of the precious metal obtained." We presume this excess loss refers to promotion profits.

DECISION of a case by the United States Supreme Court would seem to settle matters, but does not always do so. In 1908 the Court affirmed a decision of the New York courts in the Old Dominion litigation, and seemed to make it impossible for the company to recover the promotion profits for which suit had been brought against Mr. Albert Bigelow and the estate of Leonard Lewisohn. The case came up again through the Massachusetts courts, and the Supreme Court has just found in favor of the company. The judgment is for \$2,100,000 and interest, and is one of the largest ever decreed by the Court against an individual.

MANIPULATION is charged in connection with recent fluctuations in the price of Pittsburg Silver Peak stock. The mine is an excellent one, operated with conspicuous ability. Full details as to methods and costs have been available to readers of the *Mining and Scientific Press* for months, and no one who wished to know had any reason to be deceived as to the value of the shares. The serious phase of the matter is that the decision in the recent litigation was "tipped off" in San Francisco a day or more in advance of official announcement. However the circumstance occurred, it is such things that make people friendly to the proposal for recall of the judiciary.

NEW DECISIONS are constantly changing the interpretation of the mining law, and readers of our department 'Decisions Relating to Mining' will find themselves amply repaid. The department is edited by an excellent attorney who enjoys unusual facilities for keeping track of changes, and in it will be found announcements of the more important decisions in advance of their general publication.

WE print this week the first part of an elaborate study of the genesis of the lead-silver ores of the Coeur d'Alene district, written by Mr. Oscar H. Hershey. His discrimination of very ancient low-grade lead-zinc deposits that may well have been the parents of the orebodies now being worked, is an especially interesting point. In the continuation of this article Mr. Hershey will describe these mineral bodies more in detail and will discuss the relations of the ores to the faulting in the district.

SHAREHOLDERS in the Han-Yeh-P'ing Iron & Coal Company, which operates blast-furnaces and a steel plant at Hanyang, Hupei province, China, producing 140,000 tons of pig annually, have unanimously refused to sanction an agreement made by the managing director to convert the company into a joint enterprise with Japanese capitalists. The supply of ore for the Japanese Government iron works near Wakamatsu has been largely drawn, under a fifteen-year contract, from mines owned by the Chinese, and the proposed arrangement, which would have been advantageous to the Japanese, who have loaned \$4,500,000 to the Chinese company, which is capitalized for \$18,000,000, did not meet the approval of either the Chinese shareholders or China's authorities.

WASHINGTON despatches announce the defeat in the Senate of the Cummins substitute for the metal schedule for the tariff bill recently passed by the House of Representatives. There had been some expectation that a combination of Democrats and Progressive Republicans would carry this substitute through the Senate. Mr. F. G. Newlands has now offered an amendment to the House bill proposing a 10 per cent reduction from certain duties the first of next January and a further 5 per cent reduction at the beginning of each succeeding January for four years. A non-partisan tariff commission of five members, appointed by the President, is to be authorized to determine to what products the reductions should apply. In the absence of details it is difficult to say how this would work, but the recognition of the fact that reductions should be made gradually and the effort to lift the matter out of politics is commendable.

DISCUSSION of the need of revision of the American mining and land laws continues actively in the West, but unfortunately little impression is being made upon Congress. Even in so acute a matter as that of the Alaska coal lands, popular interest having been diverted, Congress seems disposed to let matters stand as they are. When an election is impending most congressmen and senators dodge responsibility for any legislation to which there is any opposition; and nothing can be done in regard to Alaska and the coal lands to which someone will not object. This situation is rapidly making converts to the theory that it would be better to pass over to the state and territories, all the remaining public lands as a free gift. There would undoubtedly be much fraud and graft as a result, but the people of the region concerned hold to the right to develop as fundamental. They are willing to make all reasonable concessions, and some which they consider unreasonable, to Eastern sentiment as to the public lands, but some way should be opened through which development

can proceed. It is evidently a choice of evils. The Salt Lake Chamber of Commerce has recently adopted strong resolutions urging that some change be made promptly, and the sentiment for similar resolutions elsewhere is strong and growing. It is asked that, pending readjustment, the Secretary of Interior interpret the law and regulations as liberally as is allowable and as much as possible in accordance with established customs. The Mining and Metallurgical Society has a committee at work studying the changes that have been proposed and the San Francisco section has been attempting to formulate the principles that should govern legislation regarding oil lands. Neither report is yet complete and in the meantime discussion of the mining law, especially by those familiar with the codes of other countries, is distinctly helpful. We call especial attention to the article in this issue by Mr. F. J. H. Merrill who brings up the peculiarities of the New York state code, and the workings of the Mexican law. The committee from the American Mining Congress, of which Mr. E. B. Kirby is chairman, has asked Congress to appoint a commission or to authorize one of its own committees, to hold sessions and hear complaints and suggestions regarding the mining law. Nothing has been done with this very sensible and practical suggestion, though a bill for a commission requested by the miners union, to investigate working conditions in mines has been introduced. A little legislation and a few less candidates for the presidency would be sincerely appreciated.

Alaskan Railway Building

Much the most sensible plan yet proposed for meeting the needs of Alaska in the matter of railway building is that embodied in what is known as the '1000-mile bill,' now before Congress. Briefly, this bill proposes: (1) to authorize the President to construct not more than 1000 miles of railroad in Alaska, the line or lines to be such as will, in his judgment, best develop the natural resources of the territory; (2) a commission of five is to be appointed, with an Army engineer as chairman and chief engineer, to have charge of the work; (3) bonds bearing 3 per cent interest and similar to the Panama Canal bonds are to be sold as needed to carry on the work, but money can only be paid out according to annual estimates and as appropriated by Congress; (4) the bonds are to be secured as to principal and sinking fund by a first mortgage on the lines built; (5) until Congress shall provide for operation by leasing or otherwise, the President is to operate the lines as military and postal routes and as common carriers, establishing public rates; (6) the commission may purchase, lease, or contract for haulage rights or transportation over any existing lines, and shall have full power to negotiate such contracts, but is not bound to either purchase or lease; (7) disagreements with existing lines as to rates are to be adjudicated by the Interstate Commerce Commission; (8) an appropriation of \$1,000,000 repayable out of bond sales, is to be made to begin the work; (9) in the work the commission may use any of the material belonging to the Government and no longer needed on the Canal Zone.

This bill has been carefully drawn, and embodies the best features of the laws under which the Isthmian Canal Commission and the Reclamation Service are working. Certain features have also been taken from the law under which railroads are being built in the Philippines. Action by the Government, sanctioned by public opinion it is true, has made it entirely impossible for private companies to raise the capital necessary to extend railroad lines through Alaska. It is equally clear that public opinion would not favor a bond grant or other public aid to a private company. Evidently, either the United States Government must

take up the work of railroad construction in the Far North or the country deliberately closed to development. The last is, we believe, far from being the purpose of any considerable part of the American people. Under the circumstances there can be no politics in such a bill as is proposed; in any event progress will be slow, and simple justice to Alaska demands that a start be made. Pass the bill and let the engineers get to work.

Tonopah Mines and Mining

It is just a round dozen years since Jim Butler made the discovery which brought Tonopah into being. While the claims now owned by the Tonopah Mining Company were not staked until August, it was in May that the outcrop of rich silver ore was found and the chain of events that led practically to the rediscovery of Nevada was begun. *The Tonopah Miner*, in an interesting special issue May 25, has summarized the history and present conditions at Tonopah succinctly, and from it the following figures are taken.

The total production of Tonopah can only be estimated, since the records of some of the companies do not include the gross production of some of the early shipments. Taking, however, exact figures so far as they are available, and estimates of company officials to cover the few gaps, the production to the close of April 30, 1912, may be stated as below:

Tonopah Mining	\$29,213,153
Tonopah Belmont	10,413,144
Montana-Tonopah	4,600,055
Tonopah Extension	1,022,950
West End Con.....	1,247,612
MacNamara	1,404,909
Tonopah Midway	1,273,626
Jim Butler	315,610
North Star	36,224
	<hr/>
	\$51,527,283

This is a large production for a district to make in twelve years, beginning in a desert and with railways, power lines, water, and all the necessities of life and work to be supplied. Even more interesting than the fact of the production, is the circumstance that the ore has been mined at a considerable profit. Tonopah is one of the districts in which there has been money made in mining and not alone in company promotion. At the time the Tonopah Mining Company was formed it was so difficult to raise the money needed, that 350,000 shares of preferred stock were sold at \$1 per share, two shares of common stock being given as a bonus with each share of preferred. The last of this preferred stock was retired with interest in February 1905. The outstanding stock of the company cost the original owners nothing. Each share has received \$8.85 in dividends and is still quoted at about \$7 per share. In all, the dividends paid have been as follows:

Tonopah Mining Company	\$8,850,000
Preferred stock retired.....	380,557
Tonopah Belmont	2,843,002
Montana-Tonopah	330,000
Tonopah Extension	300,000
Midway	250,000
MacNamara	50,000
	<hr/>
	\$13,003,559

Mr. T. A. Rickard has recently written illuminatingly in *The Mining Magazine* about 'phantom profits' and has called attention to the fact that only the money which finds its way into the shareholders' pockets in dividends, is really to be counted in measuring profits. On this basis Tonopah

has done well. Over the series of years, roughly 25 per cent of the gross return has gone to the stockholders in dividends. In addition, there has been an accumulation of surplus both as cash and in the form of ore reserves. To an extent, the surplus has been reinvested in plant or in securities of enterprises that would have but small value if the mines ceased to produce, but the Tonopah Mining Company carries a considerable sum in first-class securities and cash, and the other companies have similar, though not so large, resources. The Montana-Tonopah Company has recently purchased the Commonwealth mine in Arizona; the Tonopah Belmont Development Company is reported to have closed a deal for the App mine in California; and the Tonopah Mining Company is well known to be looking for a property in which to reinvest its surplus. It seems likely, therefore, that Tonopah will not only pay its own way, but will directly lead to active development in a number of other districts.

At present there are 260 stamps in operation in the district. The Montana-Tonopah has recently increased the capacity of its mill, the Tonopah Extension and West End Consolidated soon will do so, and the Tonopah Belmont is now building. A little less than a half million tons of ore per year will soon be treated. The practical question is how long this can be kept up.

It has always been difficult to estimate ore reserves at Tonopah. The ore, while rich, occurs in shoots that have been repeatedly faulted, and the rocks have been frequently intruded by later eruptives. The surface is covered by recent volcanics, and only most careful and systematic geologic work with core-drill and drift serves to piece together the mosaic. The district contained originally some of the great ore-shoots of the world; to the miner has fallen the problem of hunting out the scattered fragments, and doing it all at a profit. With the first rich discovery, and in the absence of exact knowledge of the faulting, there was a period of overestimation of the orebodies and underestimation of the difficulties. A good many wild-cat companies sprang up. At that time Mr. J. E. Spurr, then connected with the United States Geological Survey, studied the district and issued a report which, temporarily, made him exceedingly unpopular. Time, however, heals sores, and later Mr. Spurr, having retired from the government service, was invited to re-study the district at the expense of the companies, and they have all come to value his opinion highly. Since the Tonopah Midway Company developed an important orebody 700 feet north of its shaft in virgin ground that Mr. Spurr advised prospecting, the opinion of a geologist has come to have great weight. Many men, however, coöperated in the finding of the ore. The great shoot in the Belmont ground found in December 1909, did as much as any one thing to attract attention anew to the district and to stimulate the present revival of prosperity there. At present the Tonopah Mining Company is understood to have but a small ore reserve in the ground and to be relying mainly on dump ore and the chance of re-investing its surplus. The Belmont undoubtedly has a large reserve and the other companies are credited with ore sufficient to run two to two and one-half years without development. Beyond that it can only be said that a continuation of the present vigorous search may be expected to increase the reserve as needed for many years. Conditions in the district were never more hopeful and several new enterprises have recently been started. Tonopah is a district where the cost of finding ore is high, but where the ore is rich and the profits are large. Not every mine there is paying and not every one will pay when the whole course is run. Mistakes have been made in taking too large chances, but the mines are in good hands, excellent technical work is being done, and the community is prosperous and happy.

Genesis of Lead-Silver Ores in Wardner District, Idaho

By OSCAR H. HERSHEY

INTRODUCTION

The town of Wardner is situated in the deep narrow valley of Milo creek, on the south side of the South Fork of the Coeur d'Alene river, in Shoshone county, Idaho. The principal mines in the district are the property of the Bunker Hill & Sullivan Mining & Concentrating Co. Next in importance is the Last Chance mine, operated by the Federal Mining & Smelting Co. The Senator Stewart is at present the third in order of production, and the Caledonia and Ontario the only other producing mines. Formerly the Sierra Nevada and Crown Point mines were of some importance, but have not been operated for years.

My geological field work in the Wardner district was begun on October 10, 1908, and prosecuted continuously (except for several interruptions aggregating less than three months) to August 1910, and has continued at intervals since. Previous to this no detailed geological study of the mines had been made, although the areal geology of most of the district had been mapped in 1903 or 1904 by F. C. Calkins, assisted by W. A. Williams and D. F. MacDonald, and the mines visited by F. L. Ransome. The result of their work is included in 'The Geology and Ore Deposits of the Coeur d'Alene District, Idaho,'¹ by Ransome and Calkins, which is now the standard work of reference in the district. Mr. Calkins found that the structure in the Wardner district is too complex and obscure to enable him to do any but very generalized mapping in the time that he could give to the work. The reader is referred to his description of the formations as to their general megascopic and microscopic features. My work has been done for the Bunker Hill & Sullivan company, and its president, F. W. Bradley, and the manager, Stanly A. Easton, have kindly consented to the publication of this paper.

STRATIGRAPHY AND STRUCTURE

The Burke and Revett formations are thicker and more complex in the vicinity of Wardner than elsewhere in the Coeur d'Alene district, and I have found it practicable, in order to bring out the structure better, to divide the Burke into two members and the Revett into three members. I have also added another formation at the bottom of the series. The following table will sufficiently indicate the character of the sedimentary rocks for the purpose of this paper:

	Approx. thickness, feet.
<i>Wallace Formation</i> .—Thin-bedded, bluish and greenish, calcareous shales, calcareous quartzitic sandstone, and a thin bed of blue-gray limestone....	4,000
<i>St. Regis Formation</i> .—Purple, lavender, and green sericitic quartzite sandstone and indurated shales	1,000
<i>Upper Revett Member</i> .—Rather thin bedded, greenish sericitic quartzites and heavier-bedded white quartzites	900
<i>Middle Revett Member</i> .—Heavy-bedded, white, nearly pure quartzite	100
<i>Lower Revett Member</i> .—Thick-bedded white quartzites, alternating with thinner-bedded greenish sericitic quartzites	1,300
<i>Upper Burke Member</i> .—Thin-bedded greenish sericitic quartzites, alternating with heavy-bedded white quartzites	2,000
<i>Lower Burke Member</i> .—Thin-bedded greenish sericitic quartzites and layers of hard white quartzite; near the top is much purple-gray material indistinguishable from the St. Regis.....	1,500
<i>Prichard Formation</i> .—Gray to black shales in thin regular beds, with slaty cleavage common, and some beds of white quartzite.....	8,000
<i>Cataldo Formation</i> .—Heavy-bedded light lilac quartzites, alternating with dull greenish sericitic quartzites	1,000
	19,800

Igneous rocks are not abundant in the district. The Kellogg tunnel cuts a dark-green dike for 75 ft., 4400 ft. from the mouth. R. D. George, of the University of Colorado, from study of a thin section, reports the rock very much altered, the only recognizable primary minerals including a few altered biotite crystals and plagioclase grains. The secondary feldspar shows practically no plagioclase, and is partly interlocked with secondary quartz. Epidote, pennine, and chlorite occur. He thinks it possible that the rock may have been a hornblende-mica syenite. The gouge of the Osburn fault in the same tunnel has been partly produced by the grinding of a small basic dike. In the North Bunker Hill main tunnel a 3 to 4-ft. dark basic dike has been greatly crushed by the Osburn fault. Four fairly thick dikes of dark green basic rock, one of which I have traced continuously for 2250 ft., have been observed in the Wallace area in the Elk Creek basin. A large dike of a medium-grained gray crystalline whose appearance suggests diorite is exposed near the mouth of the Empire tunnel in Government gulch, and 2200 ft. west there is a similar dike in a greatly decomposed condition. A lamprophyre dike in which brown biotite is conspicuous appears in the Coeur d'Alene Central company's upper tunnel. A small dark-brown east-west dike near the south fork of Milo creek was pronounced by Mr. George as probably an altered basalt. Three narrow dikes of fine-grained black to dark greenish gray rock suggesting basalt occur in the Harrison cross-cut from the Silver King main tunnel and several similar dikes were seen in the Wyoming mine near Grouse creek. These are all the dikes that have been seen within the limits of any of my maps. They are never found in apparent genetic connection with any ore deposit and are probably much younger than most of the ore.

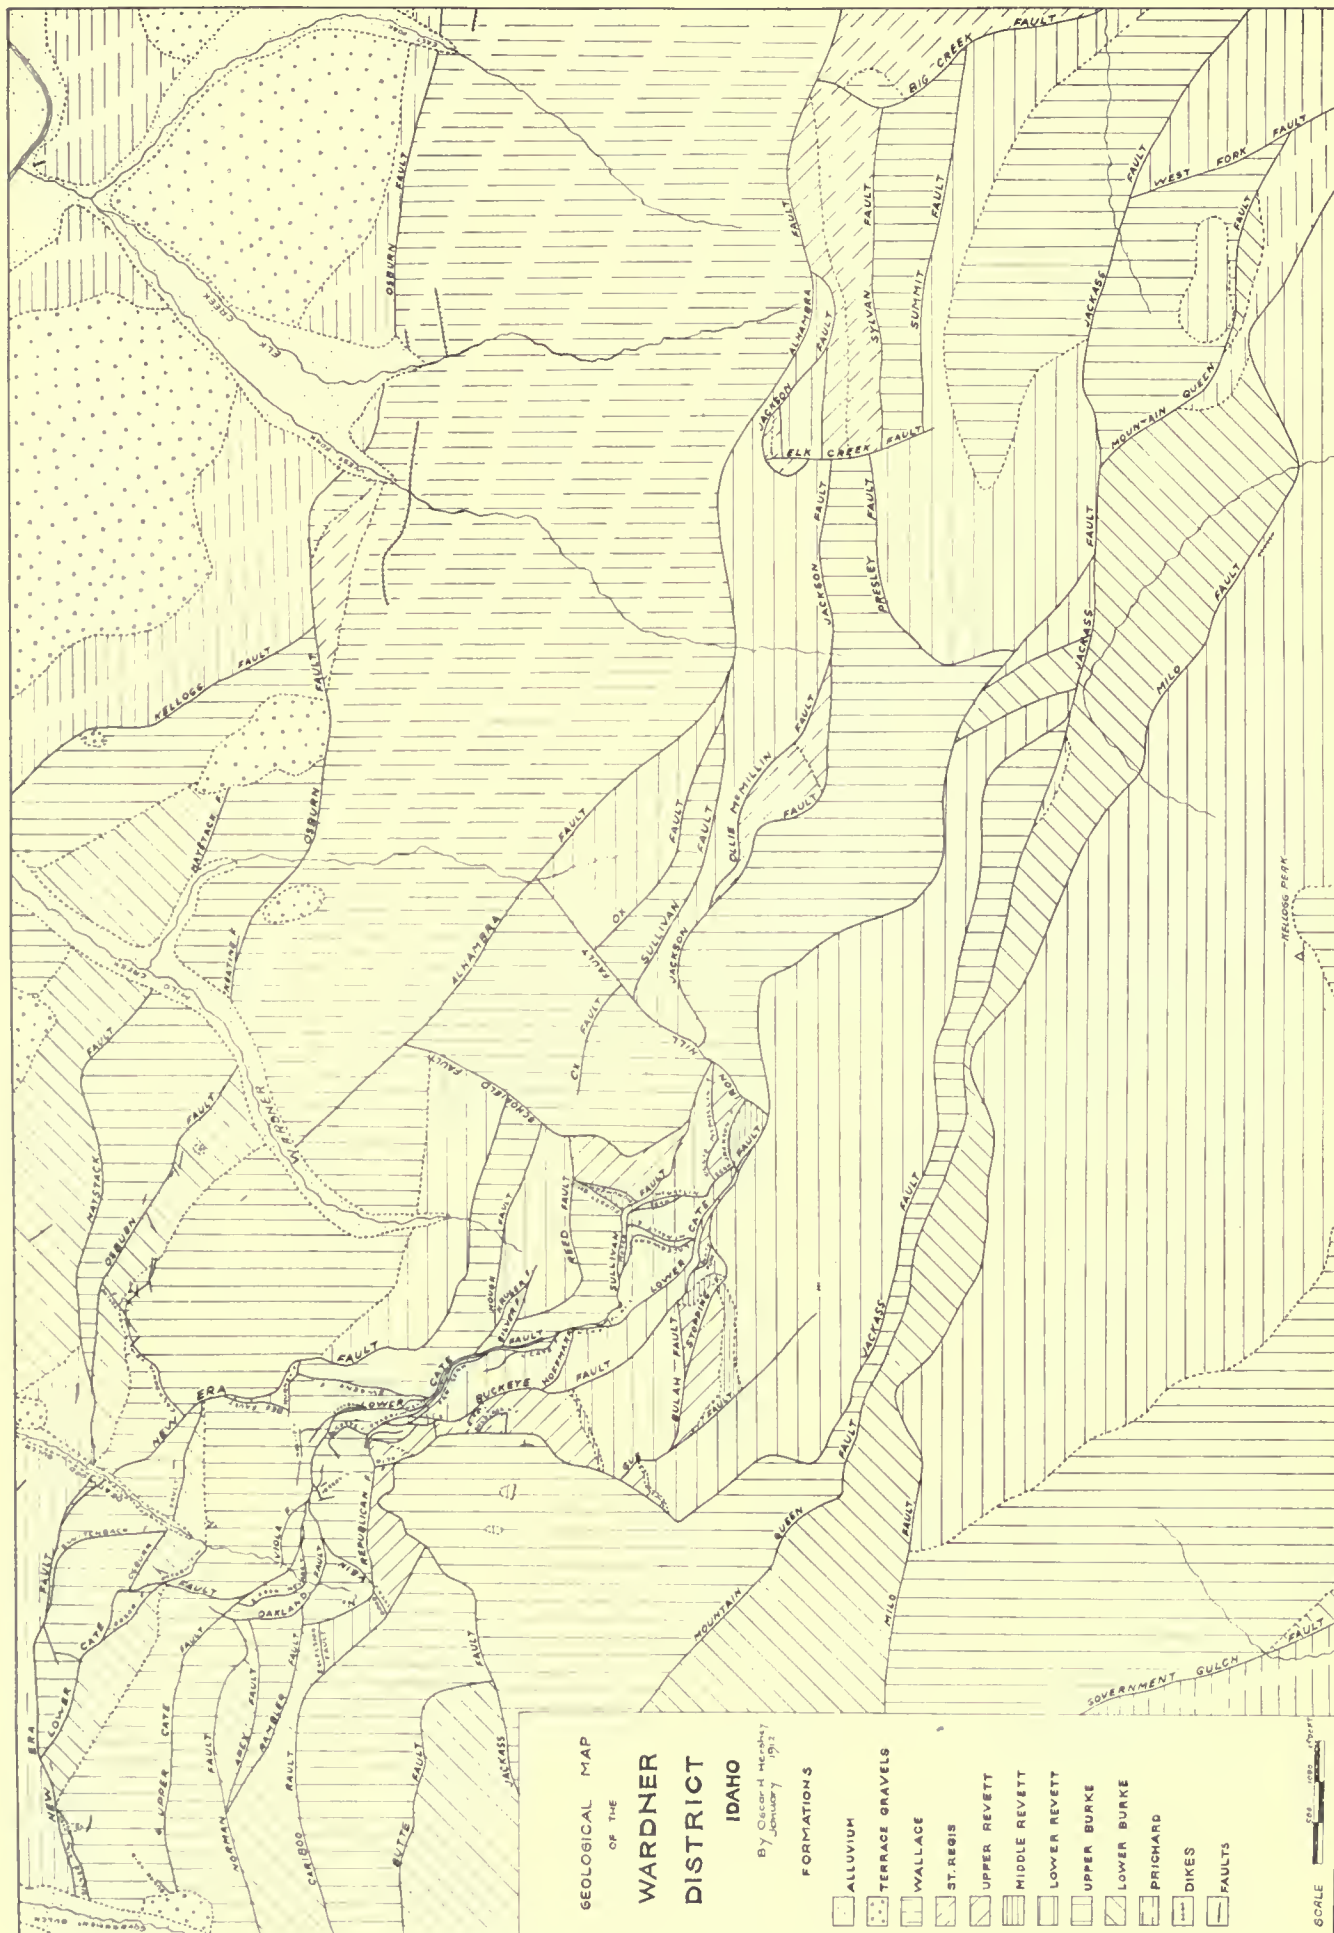

The Wardner district is one of the most excessively faulted areas of similar extent in the world. I have found it convenient to name 97 of these faults. They are divided into nine systems, each representing a distinct period and stress. The proper discussion of these faults would constitute a lengthy paper by itself, and cannot be undertaken here; but as some of the faults have preceded, some accompanied, and others succeeded the production of the lead-silver ores of the district, I will make brief references to them in alternation with the discussion of the mineralizations. The accompanying map shows the position of the traces of those faults that reach the surface of the bedrock.

STAGES OF MINERALIZATION

A notable feature of the mineralization of the Coeur d'Alene district is the presence of much siderite as a gangue mineral in the veins and as a wide dissemination in the country rock. Mr. Calkins describes² its occurrence in the latter form in the following words: "Siderite occurs in individuals of varying size; but probably the majority of them are larger than the elastic grains of the rock, the mineral being in places crystallographically continuous for a diameter of several millimetres. The form of the individuals varies much in regularity. The outlines of many of them, especially of the larger grains, appear ragged, but in such cases the boundaries are seen on close examination to be determined in large part by rhombohedral planes. In other individuals the rhombohedral form of the crystal is more marked, in some being perfect. It is an important fact that in any specimen the crystallographic boundaries can be seen cutting sharply across quartz grains, which proves that the siderite has been developed by molecular replacement of the quartz and not by filling in of cavities. The larger grains in the sandstones and quartzites frequently inclose grains of quartz and, much less commonly, scales of sericite. It is thus evident that the siderite re-

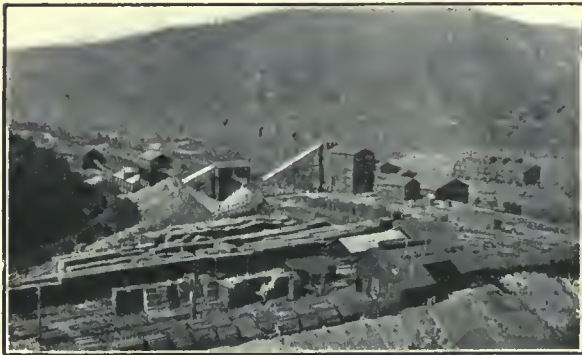

¹Professional Paper 62, U. S. Geol. Surv., 1908.

²*Op. cit.*, p. 97.

places the sericitic fine-grained cementing material more readily than the larger grains of quartz."

Certain stratigraphic horizons, one of which is near the division between the Revett and St. Regis formations and another includes the lower part of the Lower Burke and upper part of the Prichard formation, are widely characterized by disseminated siderite. In our district, southwest of the mines, it occurs in the thin beds of white quartzite interbedded with the Lower Burke greenish sericitic quartzites and in the upper part of the Prichard formation. The Upper Revett and St. Regis areas abound in it; unusually large siderite aggregates characterize a layer of lavender quartzite that is practically at the base of the St. Regis. In addition to this stratigraphic distribution, the disseminated siderite is also locally abnormally developed, particularly in a small area immediately above the Buckeye fault on the Phil Sheridan claim. The most notable occurrence of the latter form is in the vicinity of Burke, where the entire body of Burke strata at the surface in Custer mountain and on the south side of Canyon creek up to the Revett area is spotted and streaked with limonite from the decomposition of siderite; this is also the area that has produced the largest amount of lead ore in the Coeur d'Alene district. I am far from convinced that the

NEW MILL OF BUNKER HILL & SULLIVAN M. & C. COMPANY.

disseminated siderite is in any way related to the fissuring of the rock, as Ransome assumes. Mr. Ransome refers all the mineral deposits including the disseminated siderite of the Coeur d'Alene district to the action of a monzonitic batholith which he presumes to underlie the district and only to appear at the surface in the form of a few arms, the largest being the monzonite and syenite area near Gem. He explains the absence of siderite from the fairly well developed zone of contact metamorphism on the border of the Gem area on the supposition that the conditions of temperature and pressure were such as to carry the siderite beyond the zone in which the metamorphic silicates were forming. My impression, however, is that the dissemination of siderite antedated the monzonite intrusion and the mineral was, in fact, destroyed by the latter in the zone of contact metamorphism. Spotted rock from a patch of weak contact metamorphism near the Headlight mine was submitted to A. C. Lawson, of the University of California, for microscopic examination, with the suggestion that contact metamorphic minerals of green color had replaced the siderite aggregates of the original rock, and he conceded that metamorphic silicates had replaced a carbonate. The disseminated siderite under discussion, I consider the oldest type of mineralization in the Coeur d'Alene district. The carbonate of iron was probably originally present in the sediments. It may have been most abundant in the carbonaceous shales of the Prichard formation. The regional metamorphism caused more or less migration of the iron carbonate, for in its present form it is younger than the metamorphism properly so-called. The disseminated siderite may have afforded material for all subsequent siderite mineralizations in the district, so that it is not necessary to call on the solutions emanating from the monzonitic batholith to account for the presence of the iron carbonate in the ore deposits of the district.

CONTACT METAMORPHIC MINERAL DEPOSITS

Ordinary contact metamorphic deposits are not present in the Wardner district, but there are several small deposits that may be the product of waters emanating from a magma at a great depth. In the Upper Blue Bird and Phil Sheridan tunnels, there is pronounced pyrite dissemination in irregular bodies of dark gray rock in a zone 5 ft. wide, parallel to the bedding. The dark greenish gray color of the rock is due to chlorite whose unusual abundance and bunched distribution indicate a different genesis from that of most of the chlorite of the district. Pyrite is a constituent of the main contact zone near Gem, and chlorite occurs with garnet and a green mica in a small area near the summit of Custer peak, which Calkins says seems to be associated with a fissure which may have been an avenue for mineralizing vapors from the magma. Thus we have precedent for the suggestion that the chlorite-pyrite deposits in the Phil Sheridan claim, near where the Buckeye fault intersects the Middle Revett, are due to waters arising from an intrusive buried at great depth under the district southeast of Kellogg peak, a 2-in. seam in the McGatlin stope of the Sullivan mine, a piece of partly hydrated specularite found in Deadwood gulch, and irregular pockets of limonite, probably originally hematite, in the Lower Revett quartzite on the Matabeleland claim are evidently among the oldest types of mineralization in the district and may point faintly to deeply buried monzonite.

DISSEMINATED LEAD-ZINC MINERALIZATION

The earliest deposition of lead and zinc in the Wardner district was in the form of very fine ragged grains of zincblende and galena disseminated through certain bodies of the Revett quartzites in the same block as contains the chlorite-pyrite deposits. Mr. Lawson reported on two samples as follows: "No. 22 is a light gray fine-textured quartzite, mottled with darker areas of a bluish gray mineral of irregular form, with a tendency to disposition in streaks which are rudely parallel. A few crystals of pyrite ranging in size up to one millimetre are scattered through the rock. Under the microscope this rock appears as an aggregate of rather angular and interlocking quartz grains, with interstitial sericite in nests, a few crystals of pyrite, and an occasional crystal of tourmaline. Throughout this aggregate are scattered numerous irregular-shaped grains of zincblende. Associated with the zincblende is a small amount of a dark-colored opaque mineral, which may be galena. This is mostly on the periphery of the zincblende grains and thus appears to have been deposited later than that mineral. Occasionally it occurs alone. The bluish mineral observed in the hand specimen thus appears to be chiefly zincblende, with a much smaller amount of galena associated with it. A portion of this rock was analyzed by Mr. Blasdale, with the following results:

	Per cent.
Constituents insoluble in concentrated hydrochloric acid	96.42
Constituents insoluble in aqua regia.....	94.87
Lead	0.30
Iron	0.20
Copper	0.01
Zinc	1.52
Al ₂ O ₃	0.75
Sulphur	0.94
Sulphur corresponding to lead (assuming PbS).....	0.04
Sulphur corresponding to iron (assuming FeS).....	0.23
Sulphur corresponding to zinc (assuming ZnS).....	0.75

Stated in other terms, the analysis shows that the rock contains approximately:

	Per cent.
Galena	0.34
Pyrite	0.43
Zincblende	2.27

"The alumina (Al₂O₃) is probably derived from the sericite.

"No. 23 differs from No. 22 chiefly in the fact that it has a rudely schistose structure, which causes it to break

in slabs when struck with the hammer. On the parting surfaces of the rock there is an exceptionally large amount of the gray-blue mineral which occurs as a film or smear on these surfaces, and with this blue mineral there are numerous minute scales of white mica, sericite. The rock presents the appearance of having been sheared, with the development of the bluish mineral and scales of sericite along the shear planes. The rock under the microscope in its more massive parts between the parting planes does not differ essentially from No. 22, except that there is more sericite in the rock and more of the opaque mineral (galena) on the periphery of the zineblende."

These unique lead-zinc deposits are best exposed in the Smith cross-cut and Wormington drift on the Middle Blue Bird level of the Bunker Hill mine. They are in bands from 5 to 30 ft. wide, generally parallel to the bedding and in places limited by bedding planes, though there is much irregularity; also in patches which simply fade out in all directions in the solid Lower Revett quartzite. Samples have assayed, respectively, 2.51, 0.34, 0.125, 0.29, 0.09, 0.08, 0.45, 0.43, and 0.37% lead, the last three with traces of silver. The principal outcrop of these deposits in an oxidized condition is near the centre of the Blue Bird claim, near where the Buckeye fault intersects the Middle Revett band. It is a soft porous material stained by limonite and evidently leached, for the highest lead assay I could get from it was 0.09%. It largely occupies a band 25 to 30 ft. wide, bordered by hard barren quartzite, with, however, scattered bunches of it in the first 50 ft. of rock below. It is streaked, due to being controlled by lamination, and follows the stratification, dipping N.30°W. an average of 50°. Scattered bunches lead up to another band which occupies the Lower Revett immediately under the Middle Revett white quartzite. It seems to be continuous between the Buckeye and Jackass faults, becoming reduced to a regular band 4 to 6 ft. thick. It is exposed in the Hoffman raise. There is another horizon in the Upper Revett in the same locality. The mineral occurs, however, merely as scattered bunches in a zone rich in disseminated siderite which dips northerly with the bedding. The bunches are richer and the minerals are much coarser than is usual to this type; galena and zineblende can easily be distinguished with the unaided eye. Samples taken from the upper Blue Bird tunnel and the dump have assayed, respectively, as follows:

No.	Lead, per cent.	Silver, ounces.	Zinc, per cent.
1	0.97	0.4	...
2	0.13
3	0.54	0.2	...
4	0.43
5	0.68
6	0.12
7	0.13	0.2	0.60
8	0.95
9	0.74	..	1.95
10	1.07	..	2.20

In short, these deposits are hard quartzites partly replaced by fine-grained sulphides consisting chiefly of zineblende and galena, the zinc generally several times as abundant as the lead, and the silver ratio very low. The mineralization tends to follow the bedding mainly in an otherwise relatively barren block lying southwest of the disturbed belt containing the mines. There is evidence that on the dip the bands tend to jump from layer to layer, giving the mineralization in general a steeper dip than that of the bedding. It must have been deposited from very hot solutions that rose under great pressure, slowly permeating relatively porous layers of the Revett quartzites and molecularly replacing some of the rock. The character of the deposits suggests that they are another manifestation of contact metamorphic action in the district. Being apparently unconnected with faulting or other evidences of a compressive stress, a magmatic origin for the water seems far the most probable. It was expelled from the presumed monzonitic magma at great depth and forced up through the most

permeable strata. But the lead and zinc were not necessarily derived from the magma. The solutions may have dissolved them from the sediments at great depth and deposited them higher.

Certain faults, including the Forest Belle, Monument, Good Luck, Excelsior, South Fork, Stopping, Sold Again, and Pitt, that are evidently very old and fragmentary because of subsequent faulting, I place in the first system and consider them of about the age of the monzonite intrusion of the Coeur d'Alene district. The magma made its way up into the sediments by 'overhand stoping'; instead of being arched over the known batholiths, the strata tend to be depressed. Some of these early faults may be due to unequal sinking over the monzonite. The faults of the second system, including the Milo, Mountain Queen, Summit, Sylvan, Ollie McMillin, Sullivan, Ox Reed, Hough, Kruger, the eastern portion of the New Era fault as mapped, Butte, Cariboo, Rambler, Apex, and Republican faults, with displacements generally varying from 2000 to 10,000 ft., cut the district into a series of long narrow blocks trending in a west-northwest direction. They were probably the result of a strong thrust from the north. After these southward-dipping faults, particularly the Ollie McMillin and the Sullivan, were found, it would seem difficult for mineral deposits parallel to the bedding to form in such a block as that above the Buckeye fault on the Phil Sheridan and Blue Bird claims. This argument places the disseminated siderite, the pyrite-chlorite, and the disseminated lead and zinc deposits in a period preceding the second system faulting. It also constitutes the chief evidence that the presumed underlying monzonite is older than the faults of the second system. It is to be noted that subsequent mineralizations were controlled by fault fissures and present no clear evidence of genetic connection with the monzonite.

Solutions ascending along fractured zones cutting the disseminated lead and zinc deposits would be pretty certain to dissolve some of the minerals and deposit them higher in connection with the fissures and fault seams. In the Middle Blue Bird and Phil Sheridan tunnels, seams representing the oldest type of commercial ore mineralization in the district have been deposited in cracks in the quartzite containing the disseminated lead and zinc in a manner to leave no doubt that they are later. There is so much of this evidence, and it is of so clear a nature that there cannot remain any doubt that the disseminated lead and zinc mineralization is older than any of the types of mineralization that have produced orebodies in the district. There is not enough of the metals in sight in the bands as we see them to account for all of these metals in the mines, but if the disseminated deposits are a product of contact metamorphism they may increase in size and content with depth so that there may be millions of tons that, before leaching, carried 1% lead and 2% zinc. Even near the surface the disseminated deposits may be very much more numerous than we suspect. Recently the Hite drift in the Bunker Hill mine cut a bluish gray stratum near the top of the Lower Burke. It contained fine-grained sulphides and yielded by assay 0.24% lead and 0.12% zinc, though there are no ordinary lead or zinc veins near. The Keating tunnel in Deadwood gulch cut a zone near its mouth in which fine-grained sulphides are disseminated through Prichard strata belonging near the top of the formation; an assay yielded 0.10% lead, although several veins cutting the zone have no lead. Deposits of this class are generally overlooked because the miners do not see the lead and zinc minerals and attribute the dark stain of the rocks to iron minerals. I consider their possibilities adequate as a source of lead and zinc in the later deposits of the district.

(To Be Continued.)

LEAD recovered from secondary sources in 1911 amounted to 54,254 tons, or about 1000 tons less than in 1910, although the lead contained in alloys showed an increase of 856 tons. The total output of secondary lead was equal to 11.1% of the refined lead produced in the United States in 1911, compared with 11.5% in 1910.

Refractory Manganese-Silver Ores—I

By WILL H. COGHILL

In the month of January 1910 an ore sample was brought to my laboratory for treatment to determine the amount of silver amenable to cyanidation. I noted that it contained a small amount of MnO_2 , but gave no thought to this feature and put the ore through the ordinary routine tests, finding that the cyanide process could not be successfully applied on a commercial basis, and a report was made stating the refractory nature of the ore. It then occurred to me that something had been written about refractory manganese-silver ores in Mexico, and that this sample might belong to that class, so at my request the sample was left for further investigation. The client also submitted a report made by a metallurgist in Mexico, who stated that this ore belonged to a class known as refractory manganese-silver ores; that there were a great many orebodies of that nature in Mexico; that the silver seemed to be associated with MnO_2 in a way that had never been identified; that wet concentration processes failed to segregate the silver with the heavy grains; and that contrary to the rule, these ores were refractory at the surface and became more amenable to treatment upon depth. The metallurgist further stated that he knew of several mines which were idle because there was no process known by which the silver could be extracted economically and that it was yet a mystery why some ores contained manganese dioxide and were amenable to cyanidation, the dioxide even aiding by acting as an oxidizer, while others contained dioxide, which seemed to be the cause of the refractoriness. Here, indeed, is an eccentric ore, for, though the silver seems to be in the dioxide, a wet concentration of the dioxide fails to reveal a corresponding concentration of the silver. It is also a rule generally supposed to be without exception that gold and silver orebodies are more amenable at the surface than at depth, but here the conditions are reversed. Again, MnO_2 does not aid cyanidation, as is popularly supposed.¹

With this information at hand, rather elaborate experiments were made to determine the properties and possibly identify a new mineral, as well as others of a commercial nature. Samples from three localities were investigated. The first is that designated as the Arizona ore, and two samples sent from Mexico at my request are designated as the Durango ore and the Jalisco ore.

TABLE I.

SIZING TEST—ARIZONA ORE

Mesh.	Grams.	Total sample, per cent.	Ag per ton, ounces.	Total Ag, per cent.
On 80.....	15.2	25.7	13.80	18.6
80-150.....	13.2	22.3	15.60	18.4
150-200.....	6.8	11.5	17.15	10.4
Through 200.....	23.9	40.5	24.20	52.6
	59.1	100.0		100.0

(1) A sizing test on the Arizona ore (see Table I) resulted in a concentration of silver with the smallest grains, 52.6% passing 200 mesh with 40.5% of the ore, while only 18.6% remained on 80 mesh with 25.7% of the ore. The method of crushing cannot be stated, as the ore was received in a powdered condition. (2) In another sizing test, 56% of the ore remained on 200 mesh and after cyanidation assayed 12.40 oz. silver per ton (calculated from the assay of the classified products shown in Table II), and was treated in Thoulet solution (KI and HgI_2) to separate the mineral grains according to their specific gravity. Three

were secured, namely, grains with a specific gravity greater than 3.10, with specific gravity greater than 2.69 and less than 3.10, and grains with specific gravity less than 2.69. (See Table II.)

TABLE II.

SPECIFIC GRAVITY TEST—ARIZONA CYANIDE TAILING

Specific gravity.	Grams.	Total sample, per cent.	Ag per ton, ounces.	Total Ag, per cent.
+ 3.10.....	10.30	26.7	29.00	63.2
2.69-3.10.....	9.90	25.6	7.50	15.7
— 2.69.....	18.40	47.7	5.40	21.1
	38.60	100.0		100.0

It is quite apparent that the refractory silver is not enclosed in quartz grains, because inspection of the table reveals that the products consisting principally of quartz assay only 5.40 oz. per ton, while the heavy grains are high in silver. Table I shows a concentration of the silver with the smallest grains, and Table II shows a concentration with the heaviest grains. This proves conclusively that at least a great percentage of the refractory silver is in a soft heavy mineral. (3) Persistent grinding and agitating in cyanide extracted only 34% of the silver. (4) Only 32% of the silver yielded to hot strong HNO_3 upon a ten minute treatment of the original sample. (5) A similar treatment with dilute HCl with subsequent ammonia treatment extracted 69%. (6) A like treatment with strong HCl recovered 85% of the silver. Thus far it is indicated by (6) and Tables I and II that the refractory silver is chemically combined with or incorporated in an oxide which is heavy and soft. Now hydrochloric acid is the common solvent for oxidized, and nitric the common solvent for unoxidized minerals. I cannot quote this from an authority, but it is only natural that if nature had made a mineral insoluble by oxidizing it, it can be put into solution with a reducing agent— HCl . If it becomes insoluble through reducing conditions, it should be treated with an oxidizing agent— HNO_3 —to put it into solution. It is not known how many oxides were dissolved by the HCl , though it was indicated by the color reaction that MnO_2 was decomposed. So it seems that the silver was exposed to the decomposition of an oxide. Suspicion rested upon the MnO_2 . An attack was made upon it with a dilute solution of H_2SO_4 and salt. (7) It dissolved quickly, and tailing from a previous cyanide test yielded 82% of the refractory silver. The action of the sulphuric acid and salt is two-fold: it dissolves the manganese dioxide and in so doing liberates chlorine which chloridizes the silver. The consumption of sulphuric acid proved to be excessive, because it attacked the calcite in the ore. Treatment under pressure in a stoppered bottle prevented the sulphuric acid from attacking the calcite, but the pressure also prevented the evolution of chlorine, which was an essential part of the reaction; therefore the dioxide remained undissolved. (8) Now, H_2SO_4 is a good solvent for chlorine and was added with the H_2SO_4 and salt in the next test in which the charge was agitated under pressure. The reaction was complete in a few seconds, the dioxide color being replaced by the color of the iron oxide. (9) Further tests proved that H_2SO_4 attacks MnO_2 with such avidity that the other reagents had no opportunity to participate. E. M. Hamilton has stated² that he used H_2SO_4 as a reducing agent, but I was hunting for a solvent and did not have the results of his investigation in mind at that time. Though very few textbooks mention the fact, it has been known for a long while that MnO_2 is soluble in H_2SO_4 and these reagents have been used to make manganous dithionate (MnS_2O_6), some $MnSO_4$ being formed. There is probably no other case in which a mineral is as soluble in a cold dilute acid: a 1% solution being sufficient to dissolve powdered MnO_2 in a few seconds. (10) It was surprising to find that after dissolving the di-

¹A private communication from J. B. Empson in reply to an inquiry made nearly two years after this investigation was begun, reads in part: "As you rightly conclude in your letter, there are several properties in Mexico that are unable to treat these ores profitably by cyanide owing to the amount of manganese present. So far as I am aware at the present moment, nobody has been able to shed any light on this matter."

²Mining and Scientific Press, December 4, 1909, p. 156.

oxide in H_2SO_4 such a large percentage of silver was amenable to amalgamation. A sample which passed 200 mesh and assayed 24.20 oz. gave 63% extraction by amalgamation when treated in the jar mill for twelve hours. (11) A sample of cyanide tailing yielded 45% of the otherwise refractory silver during a two-hour treatment. (12) Also cyanidation of the original sample gave an 85% extraction, but this method is out of the question on account of the soluble salts formed by the acid treatment. The conduct of the dithionate toward the potassium cyanide was not investigated, but the MnSO_4 consumes cyanide and must be entirely neutralized by an alkali. This cannot be accomplished economically on account of the great amount of solution required. As the sample was used up, the investigation was reluctantly discontinued. It seemed quite possible to work out an amalgamation process in which amalgamation would proceed under pressure in a closed barrel with fine grinding and acid treatment. A pressure of about 10 lb. per square inch would be necessary to prevent the H_2SO_4 from spending its strength on the calcite, a little salt would quicken the mercury, and copper sulphate in the presence of salt would aid in dissolving the silver. As the ore contained only about 2% manganese, the consumption of sulphur on the basis of manganous dithionate being formed would be 47 lb. per ton of ore. (13) Attention was then directed to a sample from Durango, Mexico, which had been classed with the refractory manganese-silver ores. It contained 10% MnO_2 and assayed 21.85 oz. silver and 0.16 oz. gold per ton. It was stated by the superintendent of the mine from which this sample came that the ore yielded from 40 to 60% of the silver by cyanidation and that the amount of refractory silver varied directly as the amount of MnO_2 in the ore. (14) A sizing test gave a decided concentration of the silver with the smaller grains. (15) The silver displayed the same refractory disposition toward HNO_3 as did the Arizona sample, and (16) a large percentage was dissolved by HCl treatment. (17) Tests by amalgamation, hyposulphite lixiviation, and cyanidation proved the utter futility of attempting to extract the silver without fine grinding. Even MnO_2 , though it dissolves in a few seconds in dilute H_2SO_4 when crushed to pass 200 mesh,

may resist the acid for an hour when coarser than 40 mesh. (18) After crushing in an Abbé pebble mill, a siding test gave 22% on 200 mesh, 78% through 200 mesh. It was upon this material that the following tests were made. (19) The amount of gold dissolved was not influenced by the presence or absence of MnO_2 .

Table III represents a good deal of work and does not indicate a commercial method of treating the ore, but when studied from a scientific standpoint becomes interesting. The tests, which were not made in the order shown, cover a period of several months' investigation, which was carried along with other work. It was a great satisfaction to see that these fit together with so much harmony. For instance, numbers (23) to (26), inclusive, show a steadily increasing percentage of extraction, depending on the time, and that more than 18 hours treatment would probably be useless.³ Note that the mercury failed to combine with the silver in (21) and collected more than one-half of the silver in (20). In (24) the superiority of potassium and ammonium hyposulphite over the soda salt should be noted. I am not aware that anything has been written on this, but tried them just to satisfy my curiosity, with no idea of using them commercially. Calcium thiosulphate was also tried, but results were low. Sodium thiosulphate is understood to be the hypo salt referred to in these tests unless otherwise specified.

When the strong reducing power of a thiosulphate solution is taken into account and the strong oxidizing power of MnO_2 , it would seem to be useless to expect the thiosulphate to last long enough to dissolve any silver, but tests show that neither thiosulphate nor sodium sulphate are decomposed by the MnO_2 . In the tests shown in Table III, 1 assay-ton of the sample was treated in a jar-mill. Thiosulphate, when used, was about 11½% of the solution and copper sulphate about ½%. The jar-mill was simply pint glass fruit jars with rubber stoppers and lids screwed on to hold the stoppers in place. For abrasive materials marbles and small flint pebbles were used. The jars were fastened with axes parallel to a rotating shaft when grinding in solu-

³It was revealed later that all the results in this column are low on account of the ore being a little too coarse for all MnO_2 to dissolve when given the acid treatment.

TABLE III

LIXIVIATION TESTS—DURANGO ORE				
Reagents.	No.	Per cent extracted.		Remarks.
		Without acid treatment.	After acid treatment.

tion was required and were fastened with axes at right angles to the shaft when merely agitation was desired, in which case they would be turned end-over-end. All the jar-mill tests were made by grinding in solution except number (43). The solution used in (29) did good work. It is the Russell 'extra solution' of cuprous-thiosulphate, and it is claimed by the inventor that it exerts a greater solvent action on the metal, the sulphide and the sulpharsenide and sulphantimonide, that is, all but the chloride, than does the ordinary thiosulphate solution. The late O. Hofmann, in his excellent work on hydrometallurgy of silver, speaks quite disparagingly of the Russell process, stating that it is superior to ordinary thiosulphating only in laboratory tests with very strong (32%) solutions. My solutions were fairly dilute (1½%), and the superiority of the extra solution is again noticed in (36) and (37) when compared with (24), (25), and (26). (31) and (34) contained salt in addition to the other reagents. Comparing them with (30) and (25), respectively, shows that salt was a detriment when used with the extra solution. This closely parallels the condition that the extra solution must contend with in practice, as the ores are generally given a chloridizing roast in which there is an excess of salt. However, much of the salt is leached out by the base-metal leaching which precedes the thiosulphating. It may be that salt simply reduces the activity of the reagents, as does sodium sulphate in ordinary thiosulphating, but it is more likely that salt reacts with the copper sulphate (these reagents were added in the solid state and at the same time), making cupric chloride and sodium sulphate, thus preventing the copper from combining with the hypo to make the double salt and introducing sodium sulphate, which is objectionable.

reader should bear in mind that grinding was continued throughout the lixiviation tests, and it would seem that the grains would all be crushed to an impalpable powder whether or not they were 200 mesh or -200 at the beginning. Subsequent experiments indicated that some of the MnO_2 remained undissolved in the 200-mesh material; this no doubt accounts for the inferior work in (32). The high extraction in (37) as compared with (28) and (29) is probably due to the united forces of the mercury and the solution, where the mercury at once takes up the larger metallics while the solution is dissolving the smaller and more refractory particles. (38) is an imitation of the patio process in which cupric chloride is formed, which is said to be an aid to amalgamation. (41) is just a chance shot taken on account of Thomas Crowe's statement,⁵ that "ammonium persulphate is a good solvent for silver," and shows that it is a solvent in this case at any rate.

The amount of sulphur required probably prohibits a preliminary treatment in sulphurous acid. Assuming the formation of manganous dithionate, the theoretical amount required is 151 pounds per ton of ore. (45) In a test on 5 gm., sulphur was consumed at the rate of 150 lb. The absence of calcite is a favorable feature which the Arizona ore did not possess.

Table IV shows results of a series of calcination and chloridizing roasting tests on the same ore. One assay-ton of the ore was taken, and when a chloride was used it was thoroughly mixed with the ore, making 9% of the charge. The temperature is uncertain. Accurate records of the temperature of the muffle were made with a Bristol thermoelectric pyrometer, but it cannot be stated how closely they correspond to the temperature in the scorifier. The jar-mill

In using mercury in these tests it was not the aim to develop a commercial process in which mercury would be used with these salts, but it was used as a collector to simplify laboratory work. Mercury collects silver completely from the thiosulphate, and can be assayed for silver by the crucible method, giving accurate results when a flux of low fusion temperature is used. If the fluxes are not of the right sort losses will occur. The use of the glass separating funnel⁴ makes the separation of the mercury from the tailing a simple matter.

It is a question whether (32) and (33) show the importance of excessively fine grinding or that there was more refractory silver in the harder and larger grains. The

was used in the lixiviation as in Table III.

Very little has been written on the chloridizing roasting of non-sulphide ores, and it would therefore make a good field for some energetic investigators. In all ordinary chloridizing roasting the ores contain sulphides, usually of iron and copper, which become oxidized to sulphates. These sulphates react with the salt making sodium sulphate, which is a stable compound under existing conditions, base metal oxides and nascent chloride, which combines with the silver. There being nothing in this ore from which to make a sulphate, $MnSO_4$ was added (the idea being that in commercial work a small part of this ore might be treated in H_2SO_4 , making a sulphate, then mixed with the untreated

⁴Will H. Coghill, *Mining and Scientific Press*, July 9, 1910, p. 53.

⁵Researches on Cripple Creek Tellurides. *Mining and Scientific Press*, Sept. 15, 1909, p. 427.

portion and roasted) in (50) and (54), but as (53) and (54) were treated side by side, there is pretty positive evidence that the sulphate was a detriment. In (52) there is positive proof that silver is chloridized by chloridizing roasting this non-sulphide ore, the temperature at which this reaction begins being about 617°. In attempting to account for the chlorination of the silver it may be assumed that there is a reaction between the salt and the nascent oxygen from the MnO_2 , resulting in the formation of free chlorine and sodium oxide, the former chloridizing the silver and the latter combining with the silica to make slag. That the ore was not sintered in several tests in which chlorination took place does not disprove this theory, because it is probable that a large portion of the salt was dissipated in the form of a vapor, leaving only a small portion to undergo such a decomposition. Vapor could be seen rising from the charge during some of the tests, but it was not determined whether it was free chlorine or sodium chloride. A. V. Bleining, in a private communication, is inclined to think that "silver would become chloridized at about 650°C., at which temperature clay dedhydrates and is capable of reacting with many chemical substances." In (55), (56), and (57) titration failed to reveal a loss of chlorine, and a low extraction followed, though some of the silver was probably chloridized. Test (58) indicates that calcium chloride is a chloridizing agent. This is extremely interesting, because it is generally supposed that calcium oxide will steal chlorine from silver during chloridizing roasting. Here it should be mentioned in connection with the Arizona ore that the calcite would be a factor to be reckoned with in ease chloridizing roasting were to be tried. The great loss of silver as shown by (48) is to be expected when chloridizing at a high temperature. In (49) 1 assay-ton of the cyanide tailing from (44) was mixed with the 40 gm. of flour and calcined in a covered crucible at about 900° for 1¼ hour, then a lixiviation test was made by grinding in extra solution plus mercury, resulting in an extraction of 58.4% of the refractory silver. There is no doubt that the MnO_2 was here reduced to Mn_2O_3 , or a lower stage of oxidation, and that a longer period of calcination or lixiviation, or both, would have resulted in a much higher percentage of extraction. Comparing this with (46) and (47),

in which there was calcination without flour, shows that the flour is a very active reagent during calcination, either by exerting a reducing effect or preventing sintering. I do not know of any published data on the dissociation temperature of the native oxides of manganese, but wish to note here that the dissociation temperatures of the artificial oxides have been determined,⁶ namely,

MnO_2 at 530°C. breaks down in air to Mn_2O_3 .

Mn_2O_3 at 940°C. breaks down in air to Mn_3O_4 .

I have some data on the dissociation temperature of the native MnO_2 which I will publish later.

The large amount of silver in the tailing in (51) is due to the ammonia being partly neutralized by the manganous sulphate. The mercury (½ assay-ton) in (59) was badly sickened, and in (60) was not as active as it should have been.

Let us now consider an ore from Jalisco, Mexico, which contained 18.70 oz. silver, 0.05 oz. gold, 10% manganese (15.8% MnO_2), and which in the preliminary tests conducted itself in such a way that it seemed justifiable to put it in the class with the Arizona and Durango samples. It is unlike the Arizona ore in that it did not contain calcite, but like the others in that it contained manganese as an MnO_2 , quartz, limonite, and refractory silver. Now these ores were all so stained and discolored that it was nearly impossible to distinguish between a piece of quartz and MnO_2 , but it was noted that if a sample was screened and that part remaining on 10 mesh given a wash in water, followed by a brief wash in very dilute H_2SO_4 , all stains would be removed and hand sorting become a simple matter. Table V shows results of such a test on a grab sample.

TABLE V
CLASSIFICATION BY HAND SORTING, JALISCO ORE

	No.	Gm.	% of Total	Oz. Ag per ton	% of Total Ag
Mainly dioxide..	61	4.90	19.3	25.06	36.6
Mainly quartz...	62	20.50	80.7	10.40	63.4
		25.40	100.0		100.0

Here it is noted that a product assaying 25.06 oz. silver is secured from a sample assaying 13.25 oz. silver. This certainly makes it desirable to repeat the test on a larger scale. (See Table VI.)

TABLE VI

CLASSIFICATION BY HAND SORTING, JALISCO ORE

		Total % determined.	Insoluble in aqua regia, %	Limonite (calculated), %	Fe, %	MnO ₂ (calculated), %	Mn, %	Ag, %	Per cent of total Ag.	Oz. Ag per ton.....	Per cent of total....	Gm. of each.....	Number
Concentrate	63	99.9	33.2	2.5	1.5	64.1	40.6	0.12	23.6	34.00	11.8	112.5	
Middling	64	98.8	65.0	4.0	2.4	29.7	18.8	0.12	16.2	33.50	8.2	78.0	
Tailing	65	97.0	90.9	2.5	1.5	3.6	2.3	0.04	60.2	12.80	80.0	760.0	
									100.0		100.0	950.5	

COPPER equal to 19% of the domestic output for 1911 was derived from secondary sources, according to J. P. Dunlap of the U. S. Geological Survey. The total amount of secondary copper recovered, on the assumption that the brass remelted had an average copper content of 70%, was 107,104 tons, of which 13,948 tons was recovered by regular refining plants and the remainder by plants treating only secondary materials. At least 31,000 tons was recovered from clean scrap made in the course of manufacture of copper and brass ware, so that only 76,104 tons was obtained from ashes, cinders, scrap, and other material that had actually been used and discarded. While many of the railways sell or turn in their brass and copper scrap to dealers in part payment for new material, the reports received show that the railways utilized in their own shops and foundries over 13,200 tons of brass in addition to copper in other alloys.

TIN from ore mined in the United States in 1911 was confined to a small amount of metal smelted in Texas and to the shipment of a small yield of tin concentrate from Alaska, the secondary recoveries of tin form the most important domestic source of supply, according to the U. S. Geological Survey. The secondary tin recovered in 1911 was equal to 32.6% of the tin imported into the United States during the year. The figures for secondary recoveries in 1911 show an increase of 803 tons in quantity and \$2,871,240 in value, compared with the recoveries of 1910. The alloys, consisting chiefly of babbit, bronze, and solder, contained 6957 tons. The 7749 tons of recovered tin includes the tin content of products made by several plants from tin scrap. These included some tin oxide, putty powders, etc., but were mainly tin chloride.

Revision of the Mining Laws

By F. J. H. MERRILL

The problem now before the country, of formulating appropriate mining laws suited to existing conditions and capable of enforcement, is very important and very complex. The questions to be considered are many, but four of the most important have been raised in a letter issued to the members of the Mining and Metallurgical Society of America, by the Committee on Mining Law of that body, as follows:

1. Classification of lands and segregation by the Government of all minerals from surface rights.

2. Nature of the possessory right. How shall mining rights be initiated? How shall they be perpetuated? and how terminated?

3. Shall mineral lands be permanently alienated or leased? Do you advocate different provisions for the precious metals, or shall coal, iron ore, petroleum, and other minerals be treated alike?

4. If the present system of alienation of title is retained, shall we still keep the extralateral right principle?

In considering these questions it will be of value to cite examples of successful legislation by which they have wholly or in part been solved. For some six years I have conducted mining operations in Mexico and have become familiar with the mining law of that Republic. In my judgment it has so many points of excellence that, in the following answers to the questions submitted, I will make detailed comparison with the Mexican law wherever such comparison is possible.

1. The classification of lands by the Government cannot be perfectly and completely made. This is partly on account of the great labor and expense involved, and partly because, in such a classification, it will be impossible to determine, by examination, at any particular time, the future status of all lands containing mineral not sufficiently rich to be worked with profit or entirely devoid of value. There will arise the question whether or not, at some later date, such land may become of commercial value for its mineral through changes in transportation or other commercial conditions; through new discoveries or inventions in metallurgy; or through the development of new uses for minerals hitherto useless. Further, land classified by the Government as mineral land, on the best obtainable evidence, may, after detailed exploration, prove valueless commercially. Therefore, such a classification must be tentative. Hitherto, under United States statutes, public lands have been regarded as mainly either mineral or agricultural, but under the statutes of Mexico a broader view is taken and the fact is recognized that some land may be valuable for agriculture and still available for certain kinds of mining. The adjustment of questions arising from the effort to carry on the two industries simultaneously is made either by the parties interested or, in case of disagreement, by a duly appointed commission. The law of Mexico, however, differs widely from that of the United States, in that regalian right is asserted, and in all lands, both public and private, deposits of gold and silver, and also of many other metals and minerals, are regarded as property under the direct ownership of the nation and subject to the provisions of the mining code, as stated in the following translation:

"Article I, Chapter I: The following belong directly to the nation and are subject to the provisions of this law. Bodies of all inorganic substances which, occurring either in veins or horizontal beds, or in masses of whatever form, make up deposits whose composition is distinct from that of the rocks of the earth, such as deposits of gold, platinum, silver, copper, iron, cobalt, nickel, manganese, lead, mercury, tin, chromium, antimony, zinc, and bismuth; those of sulphur, arsenic, and tellurium; those of rock salt, and those of precious stones. Also placers of gold and platinum."

The segregation, by our Government, of minerals from surface rights, in lands belonging to the nation, would be

a new departure, yet it seems feasible. On mature consideration, however, it becomes evident that some minerals may not easily be separated from surface ownership. In Mexico the following belong exclusively to the owner of the soil:

I. Bodies or deposits of combustible minerals in all their forms and varieties.

II. Bodies or deposits of bituminous materials.

III. Bodies or deposits of salts, which outcrop on the surface.

IV. Springs of surface and subterranean waters, subject to the provisions of the common law and those of special acts in regard to water, without conflict with Article IX [of this code].

V. The rocks of the earth and the minerals of the soil, such as slate, porphyry, basalt, and limestone, and soils, sands, and clays.

While, in the United States, public sentiment might accept legislation separating from surface ownership some mineral deposits in groups I and II, there would be a serious question as to the propriety and practicability of segregating from surface rights all those included under groups III, IV, and V. Under existing federal statutes this question of segregation of surface from mineral rights could arise only in relation to public lands, but in a recent publication of the U. S. Geological Survey, Bulletin 505, A. C. Veatch has expressed the view that the United States is in possession of regalian rights, that is to say, rights of ownership in all deposits of precious metal on lands at any time owned by the nation.

In his very important article on 'The Mining Law' in the *Mining and Scientific Press* of March 9, 1912, H. V. Winchell, in criticizing this view, quotes from 'Snyder on Mines,' Vol. I, p. 15, as follows:

"Neither regalian right nor anything similar has ever existed in or been asserted in the United States."

While our federal government has never asserted regalian right, this statement by Snyder is not wholly accurate, for such a right has been distinctly asserted by the State of New York, as will be seen in the following:

General Laws of New York, Public Lands Law, Section 80.

"The following mines are the property of this state in their right of sovereignty:

1. All mines of gold and silver discovered or hereafter to be discovered within this state.

2. All mines of other metals and of tale, mica, or graphite discovered or hereafter to be discovered, upon any lands owned by persons not being citizens of the United States.

3. All mines of other metals and of tale, mica or graphite discovered or hereafter to be discovered upon lands owned by a citizen of the United States, the ore of which, on an average, shall contain less than two equal parts in value of copper, tin, iron, and lead, or any of those metals.

4. All mines and all minerals and fossils, discovered or hereafter to be discovered, upon any lands belonging to the people of the state."

It is further provided that the discoverer of a mine on state lands, after filing notice of discovery, may work such mine, and his heirs and assigns shall have sole benefit, on payment of a royalty of 2% of the market value of all such products.

The first legislation in New York on this subject was enacted in 1789 and the underlying principle of these provisions seems both to include and to exceed that stated by A. C. Veatch*: "In all states where the federal government has never owned the land, and there are 19 such states, the ownership of the precious metals lies with the state government." In New York, as in Mexico, the Government has claimed not only 'royal mines' but certain deposits of base metals and of non-metallic minerals. Attention is called to this as a detail of history, and not because I regard such legislation as desirable. In fact, gold mines in New York have largely existed in the prospectuses of promoters who claim to have 'secret processes' of extraction.

*U. S. Geol. Surv. Bull. 505, p. 116.

Whether the federal government has hitherto been in possession of an unrecognized regal right, which it can assert by legislation, is a question which could only be decided by the courts. Thus far it has not been recognized in the federal statutes, and apparently the decisions of the United States Supreme Court have never discussed it. It can hardly be doubted, however, that authority on the part of the federal government to assert this right could have come to it from the same source as the authority which was early assumed by the state of New York. Probably the majority of thoughtful persons, experienced in mining, will agree that, at this late date, it is better that such a right should not be recognized even should it theoretically exist. Certainly it should not be asserted in a retroactive way.

2. In my judgment the general features of the Mexican mining law are essentially satisfactory in the details covered by this question. In Mexico mining titles are regarded and treated as real estate and are subject to the same conditions regarding ownership, contracts, and conveyances. The distinctions are that no surface rights are conveyed, and that the continuance of ownership depends on the payment of a yearly tax or rental of ₧6 per hectare. But the latter distinction is trivial, for improved real estate also is subject to a tax, in default of the payment of which the title may be lost.

The right is initiated by making formal application through the local agent of the Secretaria de Fomento, accompanied by a licensed engineer's survey of the desired property, made under prescribed rules, and depositing with the local agent of the Treasury a sum of money equal to ₧5 per hectare of surface area. This deposit is held until the title has been signed and issued by the President of the Republic, and should the title not be granted, the money is refunded to the locator, but the agent's fee, some ₧35, is not refunded. The title is perpetuated by paying the tax of ₧6 per hectare, and may be terminated by the Government at the end of three months of delinquency in any installment of the tax, which is payable at intervals of four months.

3. As indicated above, a leasing system may be virtually indistinguishable in practical results from one of permanent alienation; but in Mexico, as already stated, surface rights are not leased with the minerals. In California, when the suggestion was first made that public oil land should be leased by the Government, there was a strong expression of feeling on the part of many of the oil men. Their view was that if, in future, oil lands must be leased, the persons who secured their lands under the present law would have an advantage in obtaining their ground at less cost than those who came later. The justice of this objection would depend largely on the detail of the proposed legislation. Under the Mexican law no one regards the mining tax as a hardship. And here it must be made clear that there is a material difference between leasing on a rental per acre, as in Mexico, and leasing on a royalty involving supervision of business detail by a Government bureau. The latter might be open to serious objections. In addition to the mining tax, Mexico imposes an internal revenue tax on bullion and also a coinage tax.

In answer to the question whether coal, iron ore, petroleum, and other minerals shall be treated alike, it must be emphasized that, in one particular, petroleum should be differently treated, because a petroleum property cannot be protected from lateral encroachment. In other words, a tract of oil land lying idle and surrounded by producing wells may lose the larger part of its oil without one well being drilled upon it. This is evidenced in the Santa Maria field in California, where, on account of special local conditions, it has been found possible to operate with one well to each forty acres. Loss due to this condition can be prevented only by drilling and operating wells along the boundaries. In simultaneously operating adjoining properties, it is customary to sink wells at equal distances on either side of the intervening boundary line, so that the encroachment is mutual and equalized.

Possibly legislation could be enacted which would provide adequate compensation for lateral encroachment on public oil lands or on private oil properties lying idle, but this would not be an easy matter.

Whether coal and iron ore should be treated differently from gold, silver, copper, lead, and zinc is a question properly left to those specially experienced in the mining of coal and iron. Special provision will be needed for some of the minor minerals.

4. The principle of extralateral right is undesirable, but cannot immediately be taken from those who already possess it. The regulation of this matter may be difficult. Probably the only solution is by legislation providing for vertical plane boundaries in future locations and permitting those who now possess extralateral rights to use them only until the orebodies affected have been exhausted. This could be accomplished by providing that at the end of some reasonably long period, say 10 to 20 years, all such rights should terminate.

Zinc-Aluminum Alloys

Twenty years ago the Institution of Mechanical Engineers formed a committee to undertake researches into alloys. In those days Roberts-Austen was always to the fore in such work, and he was appointed to the chairmanship of the committee. His strong point was not steel or copper, but gold, and he caused dismay among the engineers and steel men by switching the inquiry along the lines of his favorite metal. When the first report was presented, J. O. Arnold, of Sheffield, indulged in unparliamentary language, publicly stating that the report was "not worth a rush." However, those times are now gone by, and nine other reports have since been issued. Nowadays the subject matter of the research is more in the line of the Institute of Metals, a society founded four years ago and showing wonderful vitality. The tenth report, recently issued, covers the alloys of aluminum and zinc. To the average reader the description of a new alloy of aluminum, zinc, and copper is probably the most interesting part. This alloy has given the most important results of all the light ternary alloys so far tried. The composition is 72% aluminum, 25% zinc, and 3% copper. In the cast state it exhibits little or no ductility, but with sand castings and chill castings the tensile strength is 18,25 and 20,22 tons per square inch, respectively. With the usual plant and methods employed with aluminum, the hot-rolling of this alloy is difficult, but as perfectly sound bars have been obtained, it is believed that with modifications it should be possible to roll it commercially. Great care is required as regards temperature regulation; if the alloy is too hot it breaks into powder, and if too cold it becomes excessively hard. The rolled alloy exhibits considerable ductility, but cannot be drawn into wire; the thinnest section obtained had a diameter of $\frac{3}{8}$ in. Remarkable results were obtained in the tensile test on $\frac{1}{2}$ -in. rolled bar. This showed a yield-stress of 27 tons per square inch, an ultimate stress of 31.7 tons per square inch, and an elongation of 21%. By cold-drawing down to $\frac{3}{4}$ -in. diameter, the yield-stress is further raised to 31.5 tons per square inch and the ultimate stress to 33.3 tons, while the elongation is reduced to 13%. The specific gravity in this condition is 3.29. A compression test gave 24.21 tons per square inch as the yield-point, and 29.02 tons as the collapsing stress. The general conclusion of these and other tests is that this alloy has the greatest strength in proportion to its weight of any yet discovered.

JUNK collectors and dealers pay low prices for small quantities of scrap metals, but the competition for the scrap, drosses, skimmings, and other waste products of large users of metals is very active. It is necessary for some uses to employ primary or virgin pig metal, but as a general rule secondary metals, in whole or in part, can be used by manufacturers. They are in active demand and displace an equivalent quantity of primary metal.

Law of the Pay-Streak in Placer Deposits

By J. B. TYRRELL

*The pay-streak is a feature in the structure and growth of the valley in which it occurs, its formation is governed by certain geological laws, and those laws should be recognizable without great difficulty if the growth of the valley can be traced with reasonable accuracy. In what is now known as the Klondike district, marine sediments were laid down at various periods up to the beginning of Tertiary times, and after their deposition they were raised, crushed, and bent into their present form and position. The country was then worn down to base level, and a peneplain, the remains of which can now be seen at an elevation of about 3300 ft. above the sea, was formed. This peneplain may be called the 'Dome peneplain,' as portions of it are distinctly recognizable in the vicinity of the mountain known as the Dome. The period of its formation may be designated as the first cycle of erosion, since the history of the gold-bearing gravels would appear to begin with it, and no gravel deposits have yet been recognized on it.

After the Dome peneplain was formed the first period of elevation began, and the country was raised to a considerable height above the sea. The Yukon river, which had probably been outlined at an earlier period, immediately began to erode its channel, while the water, which fell as rain on the elevated Klondike land, carved out smaller valleys to carry the drainage from it to the larger river. As the Yukon river was a powerful eroding agent, it deepened its valley rapidly, and at the same time the smaller streams radiating from the Dome, such as the Bonanza, Hunker, Dominion, and Sulphur creeks, kept excavating their channels to keep pace with the lowering of the bottom of the valley of the Yukon river, which was the master-stream into which they flowed.

During all this time the valleys of these smaller streams maintained the general character of gulches or young valleys, with V-shaped cross-sections. But little gravel or loose material remained on the rock which formed the bottoms of their channels, for it was being constantly moved downward by the current toward the Yukon river, and, on the way, was helping to cut deeper and deeper into the rock over which it traveled. While this process of deepening the valleys was in progress, detrital material was being constantly brought into them by wash from their sides and by smaller streams from the ridges between them, and, as the rocks from which this material was derived was gold bearing, the detritus contained a small quantity of gold. Thus gold and particles or masses of rock were fed gently into the main streams.

Now a stream with a given velocity is able to carry pebbles of a definite size and specific gravity. If the specific gravity is constant, the diameter of the pebbles which it can carry will vary according to the square of the velocity, and if the velocity remains constant, the size of the pebbles will vary according to the specific weight of the substance composing them weighed in water. For instance, if the velocity of a stream is doubled, it is able to carry pebbles of quartz four times the diameter, or 64 times the weight, of those which it could carry before. If, on the other hand, one pebble is of quartz and the other is of gold, which is 11 times as heavy as quartz weighed in water, the volume of a pebble of quartz which can be carried by the current will be 121 times (11.2) as great as that of a pebble of gold, or, in other words, the diameter of the pebble of quartz will be about five times the diameter of the pebble of gold. Again, if particles of quartz and gold of equal size are dropped into water the gold will sink to the bottom with more than three times the velocity of the quartz.

Where the fragments of rock, consisting of quartz, schist,

granite, and gold, are fed into the stream, they are caught by it and carried along the bottom until they lodge in some crevice or opening, from which they cannot be dislodged except by upward currents, and these upward currents will lift any pebbles of quartz or similar rock which are less than five times the diameter of nuggets, or grains of gold occurring with them, before they will lift the gold, even if the quartz and gold are equally accessible. This makes the removal of the gold exceedingly difficult as long as the crevice remains, for the upward currents will constantly carry away the finer and lighter rock, and undermine the grains of gold and allow them to sink. When the finer and lighter material is carried away, the coarser and lighter pebbles are exposed to the force of the current, and the smaller and heavier grains of gold are able to obtain lodgment beneath and between them so as to be almost inaccessible. In fact, under normal conditions, the spaces between the lighter pebbles are large enough to hold any grains of gold which could be carried by the current flowing over them. It is thus shown that gold will remain permanently in a fissure of the rock at the bottom of a stream as long as that fissure remains in existence, and also that it will remain between or beneath larger pebbles and boulders as long as these remain unmoved.

Now, the small streams of the first period of elevation, which developed into, or was succeeded by, the second cycle of erosion, continued to cut down their channels as long as the Yukon river continued to deepen its valley. During all this the bottoms of their valleys continued to act as sluices, which were more or less efficient agents in collecting and retaining gold according to the character of the rock of which they were formed. If the rock where the gold was discharged into the stream was a fissile schist standing on edge, the gold would be caught at once, while if it was a massive granite or other similar rock, without joints or fissures, or a smooth horizontal schist, the gold would be carried down-stream over it until it would be caught by some more favorable rock. In this way there would be rich places, poor places, and blanks in the streak of gold deposited in the bottom of the valley.

As the stream would continue to deepen its valley very gradually, almost imperceptibly, by downward erosion, those places which were underlain by schists standing in a vertical or highly inclined attitude would continue to hold the gold which they had already caught, and to accumulate more, for fissures would open as fast as the surface was worn away, and the gold would sink into them as they opened. On the other hand, those places which were underlain by a harder bedrock, and which had probably also a steeper grade, would remain barren. If, again, the character of the bedrock should change from 'open' to 'tight', the gold which it had held might be undermined by the continual downward erosion, and so be brought again within the influence of the transporting power of the running water, by which it would be carried along to find some new resting place farther down the stream.

When the Yukon river had eroded its valley down to base-level, the smaller inflowing streams were no longer obliged to continue to deepen their respective valleys to keep pace with it, but were able to cut them down to grade and then to widen and form flood-plains in them, thus changing the V-shaped valleys into U-shaped ones, floored by alluvial plains through which the rivers and brooks meandered from side to side. A normal stream decreases in velocity and gradient as it descends its valley and reaches grade near its mouth before it has cut down the rest of its valley to grade. So, when each of these streams had cut down the lower portion of its valley to correspond with the base-level established by the Yukon river, it would begin to meander and extend the width of its floor. At the same time, with the decrease

*A paper presented before the Institution of Mining and Metallurgy, May 16, 1912.

in gradient, the velocity of the current would decrease, and its transporting power would be diminished. Consequently, part of the detrital material which would be brought down by the upper and swifter portion of the stream would be dropped where the current was retarded by the decreased gradient, and would lodge in the bottom of the valley and form a flood-plain or alluvial plain. This alluvial plain would be first formed where the V-shaped valley changed into a U-shaped one.

Most of the gold which had previously been discharged into the stream with the detritus from the adjoining hills and ridges would have already lodged in the bottom of the V-shaped valley, and would have settled down almost vertically as the bottom was lowered by the downward erosion of the stream. If any gold was carried down to the mouth of the V it would have a strong tendency to settle just where the velocity of the current was diminished, or at the head of the flood-plain, and the weaker current would have no power to pick it up again, or to release that gold which was already present beneath it on account of having been previously caught in the bottom of the V-shaped valley. Thus the pay-streak would be formed. Afterward the gravel, sand, and alluvium of the flood-plain would be deposited over and beyond it, but it would continue to mark the position of the bottom of the old V-shaped valley, no matter how wide the bottom of the mature valley might be afterward extended. After a flood-plain had been formed at the mouth of a valley, the river farther up-stream would still continue the downward erosion of its channel until it reached the grade of that below it, when lateral planation and the formation of the flood-plain would begin. Thus the flood-plain was formed gradually up the valley from its mouth, and always, where the old V-shaped valley changed into a U-shaped valley, there was left a trail of gold beneath it.

The gold which was collected and stored in the bottom of the V-shaped valley had been derived from the rocks of the adjoining country. At the same time the lighter material derived from the disintegration of these rocks had been carried through the valley and out beyond its limits, for the stream was then cutting down and enlarging it, and not filling it up, and there was very little room beside the stream for the accommodation of loose rock material. At the head of the flood-plain this gold, which had been concentrated from the rocks of the surrounding country through previous ages, was gradually covered, and hemmed in on both sides, by gravel and alluvial material brought down by the stream at a later date. Therefore the gold in the pay-streak was derived from its home in rocks at a date which preceded that of the formation and deposition of the gravel which overlies and surrounds it.

The gravel of the flood-plain may itself contain some gold which had been washed down the stream with it, or which had been washed into the valley from the sides, but this gold is usually very fine, such as might readily be carried by the stream for long distances. If, after the flood-plain was once formed, the stream should continue to deposit gravel to considerable thickness in the bottom of the valley through which it meanders, the source of supply for the gold would, on account of the general wearing down of the country, become more and more remote, and the average gold content of the gravel would gradually decrease from below upward.

The laws governing the formation and position of the pay-streak in an alluvial plain in the bottom of a valley may therefore be stated as follows:

1. It was formed in the bottom and at the mouth of the V-shaped valley, which was the young representative of the present valley.
2. It marks the position formerly occupied by the bottom of that V-shaped valley.
3. The gold contained in it was washed out of the surrounding country and collected into approximately its present position before the gravel of the flood-plain (or terrace) was deposited over and around it.

It has been assumed for purposes of illustration, that the growth of the valleys in the Klondike district, which

empty into the Yukon river, was continuous and regular throughout the second cycle of erosion, and in view of their symmetrical character and the regularity of the pay-streak, which has been shown to have existed in them, it is probable that this assumption is not very far from correct; but nevertheless there were doubtless interruptions and cessations, both in the regular course of erosion and sedimentation. After the Yukon river had cut its valley down to base-level in this White channel period, or second cycle of erosion, the tributary streams flowing from the Klondike district also widened their valleys and formed flood-plains, as has just been described.

Then there was a long period of quiescence, during which the base-level of the country was raised, permitting heavy accumulation of gravel in the valleys, while at the same time the hills and ridges were worn down to mature forms. At the mouth of the valley of Bonanza creek the local gravels, derived from the watershed of the creek itself, accumulated to a thickness of more than 200 ft. These gravels can still be recognized forming terraces at many places on the hills several hundred feet above the bottom of the valley, and R. G. McConnell,[†] who has carefully measured them, has shown on a map accompanying his report a pay-streak running in a straight line through and beneath them. According to the laws here formulated, this pay-streak was formed in the bottom of the old V-shaped valley, which represented the valley of Bonanza creek at the White channel period in its youthful stages, and it now tells us the original position of the bottom of the V-shaped valley.

Just before, or at the termination of, the second cycle of erosion, the Klondike river brought a heavy load of sediment down from the mountains to the east, and covered the bottom of its own valley, and the mouths of its tributary valleys, with a bed of gravel, which, opposite the mouth of Bonanza creek, has a thickness of 150 ft. The influx of this gravel caused the lower portion of the latter stream to move westward, almost to the limit of its own flood-plain, and to be ready to begin a new rock valley with the advent of the next erosion cycle.

After the deposition of this upper gravel in the valley of the Klondike river, a period of elevation[‡] set in, and the third cycle of erosion was inaugurated which has continued down to the present time.

With the advent of this cycle of erosion the Yukon river was rejuvenated and again began to actively deepen its channel, and at the same time the tributary streams also began to deepen their old channels, or to cut out new ones, in order to keep pace with the master-stream. The Klondike river, the largest affluent of the Yukon in this district, probably did not lag very far behind it in the work of downward erosion, but its tributaries, such as Bonanza and Hunker creeks, undoubtedly continued to flow in narrow V-shaped valleys as long as the main stream was actively engaged in deepening its channel.

Opposite the mouth of Indian river the Yukon river has not deepened its channel as far below the level of the channel of the second cycle of erosion as it has at the mouth of the Klondike river, and the Indian river itself, being a smaller stream, has not cut back its valley as fast as the Klondike river, so that Dominion, Gold Run, Sulphur, and the other tributaries of Indian river have not had the same opportunity to deepen their channels as the tributaries of the Klondike river.

During the third cycle of erosion the smaller streams, and especially those flowing into the Klondike river, have cut down their channels to grade in narrow valleys, and

[†]Report on 'The Gold Values in the Klondike High Level Gravels,' by R. G. McConnell, Ottawa Government, 1907.

[‡]In a paper published in the *Scottish Geographical Magazine* for June 1900, entitled 'The Basin of the Yukon River in Canada,' I stated that this elevation was probably in the nature of a tilting from the southwest toward the northeast, but in view of the fact pointed out by Mr. McConnell that the rock terrace of the White channel period, on the sides of the valley of the Yukon river, now rises steadily northward from the mouth of Stewart river to the mouth of Fortymile river, this opinion is no longer tenable.

have widened the bottom of those valleys by lateral planation and the formation of flood-plains, giving them a U-shaped profile. Terraces have been formed on the sides of the valleys, indicating halts in the progress of downward erosion, and narrow V-shaped gulches still carry

small, or intermittent, streams into the sides of the main valleys. Pay-streaks, which have now been almost entirely mined out, ran beneath the flood-plains down the bottoms of these valleys, or crossed the terraces on their sides, and other pay-streaks were in process of formation in the gulches until that process was arrested by the work of the miner.

It is not necessary for the present purpose to follow the growth of these younger valleys in detail, or to trace the formation of the pay-streak in them, for that was clearly governed by the laws which have been already enunciated, but it will be interesting to indicate a few of the eccentricities which may have been introduced in the pay-streak by irregularities in the growth of the valleys in which they were formed. Difference in the character of the bedrock will produce a marked difference in the quantity of the gold in the pay-streak. A variation in the supply will also influence the richness of the deposit, as may be clearly seen in many of the small lateral streams, which flow into the main creeks. Some of these cut across the old pay-streak of the second cycle of erosion, and where this occurs the gravel in the bottom of these streams is enormously enriched. Temporary cessation of downward erosion, with the corresponding formation of flood-plains at successive levels, would appear, however, to exert the most powerful influence in affecting the nature of the pay-streak and introducing irregularities into it. Suppose that a valley has been eroded down to the first level, and that a flood-plain has been formed at that level. The pay-streak will occupy its normal position in this flood-plain on the line of the bottom of the old V-shaped valley, as shown in Fig. 1. If the stream is rejuvenated and again begins to deepen its valley, a number of other conditions may occur.

1. It may cut down its channel directly beneath pay-streak No. 1, in which case the pay-streak will simply be lowered, and will contain practically all the gold from the older pay-streak, as well as any gold that may have collected into the channel since the time of its formation, as shown in Fig. 2.

2. It may cut down its channel to one side of pay-streak No. 1, and while still actively engaged in downward erosion may undercut the pay-streak and allow the gold to slide down the side of the valley into the stream, where it will be carried downward until it finds a new resting place. In this case, too, the second pay-streak will contain most of the gold that was in the first, but it will have undergone a decided movement down the stream. (See Fig. 3.)

3. The stream may cut out its second V-shaped valley entirely to one side of the first pay-streak, but when it again begins the process of lateral planation, and forms its second flood-plain, it may undercut the pay-streak and allow it to fall into the meandering stream, where part of it may quickly sink and form a pocket off the line of the true second pay-streak altogether (though it will give an indication of the former position of the first pay-streak), while part of it may be carried down by the stream and distributed in its winding channel. The true second pay-streak itself will, in this case, probably be very weak. (See Fig. 4.)

4. The second channel may be formed altogether to one side of the first pay-streak, in which case the first pay-streak will be on a terrace, and the second pay-streak will probably be weak. (See Fig. 5.)

Any of these conditions may occur in different parts of the same valley, and their relative intensity, or rapid changes from one to another, may cause great variations in the character of the pay-streak. A great number of stages in the deepening of a valley would allow for a still greater complexity in the character of the one or more pay-streaks which might be found in it, and these might be still further added to by a filling of the valley with detritus and part re-excavation at one or more different times. But, for the period in which it was formed, the pay-streak represents the bottom of the young V-shaped valley, which formerly occupied part of the present valley.

Vipond Porcupine Gold Mines Co., Ltd.

By W. S. DOBBS

The property of this company consists of four claims situated about one-half mile south of Pearl lake, in Tisdale township, and southeast of the Hollinger mine. Work has been carried on continuously since April 1910. A test-mill consisting of one Nissen stamp was erected the last week in February 1911, and was in operation continuously till the fire on July 11 destroyed the entire plant. The mill clean-ups amounted to more than \$6000. The plant consists of a 12-drill Sullivan compressor and a Jenckes hoist in one building, a shaft-house, two bunk-houses, cook camp, office, and assay office. A mill is being built. The assay office is furnished with a complete series of appliances, rotary and jaw crushers, a Braun combination muffle and crucible furnace, scales for weighing crucible charges, and a button balance, anchored and free from all vibrations of the building.

On the northern claim, some 27 veins have been discovered, but the principal development has been on the veins known as No. 2 and No. 3. Besides two test-pits or prospecting shafts and an open-cut on No. 3 vein, the principal work has been carried on from the main shaft, which has been sunk to a depth of 300 ft. As soon as a station has been cut and a sump sunk, cross-cutting will be done to intersect veins No. 2 and 3. The principal work has been done on the 100 and 200-ft. levels. On the 200-ft. level 500 ft. of driving has been done on No. 2 vein, and 140 ft. on No. 3. This showed good ore at the southwest end. On the 100-ft. level 600 ft. of driving has been done on No. 2 vein, the westerly end of the drift being stopped because of the proximity of the swamp. At the east end the latest assay across the face of the drift showed ore worth \$98 per ton. No. 3 vein has simply been cross-cut and is 25 ft. wide. It assays \$12 across this width. On the 100-ft. level an irregular mass of quartz lenses interspersed with hornblende schist, and assaying from \$3.50 to \$6 per ton, has been cut. This zone is 50 ft. wide.

The principal veins occur in a shear-zone of amygdaloidal basalt altered to a hornblende, and in some places to a sericite schist. The crushing and shearing has also opened a series of channels, along which the depositing solutions operated, so that this shear-zone is a mass of fine stringers, and along certain well defined lines much larger orebodies have been formed. One other result of this action has been to dissolve the calcite and carbonates of iron and magnesium which fill the amygdules, and re-deposit the material as stringers through the fracture planes.

The framework of the mill is practically all in place, the roof is rapidly being completed, and the erection of machinery was commenced April 22. The flow-sheet and milling practice is to be as follows: The ore will be delivered at the mill by a tram from the main shaft and passed through a Buchanan jaw-crusher, then after passing through Sturtevant rolls which will reduce it to 3/4-in. size, by elevator and conveyor to ore-bins. From the bin the ore will pass through James automatic feeders, to Hardinge 4 1/2-ft. ball-mills, then through Colbath classifiers, the slime passing directly to the amalgamating plates, while the sand is to be passed through a 6 1/2 by 6-ft. Hardinge tube-mill. The product of the tube-mill will be passed over a second Colbath classifier, the slime from this passing over the amalgamation plates and the sand being returned to the tube-mill for recrushing; the whole in time being slimed and passed over the amalgamation plates.

The mill is designed so that two units of 75 tons capacity each can be operated in parallel; each unit being entirely independent. The construction of a cyanide plant was in contemplation, but in view of the excellent results obtained in the Dome mill, the management of the Vipond has decided to test the present plan of sliming and amalgamating before proceeding with any further ore-treatment. The manager, C. H. Poirier, estimates that one unit at least will be in operation by May 20, 1912.

A Chart of Ore Deposition

By CHARLES R. KEYES

In so far as workable orebodies are concerned, descending currents of water are probably more important than the ascending. In the diagram shown herewith, the courses of the various circulations are represented as merging at a single point or along a given line. The latter may be an old mineral vein or it may be a recent fault-plane. In either case the currents reach ground-water level, where their burdens of oxidized ores are mainly reduced to sulphide form, and dropped to form the bonanza zone, or layer of secondary sulphide enrichment. A minor part goes on downward into the profound zone. The proportion

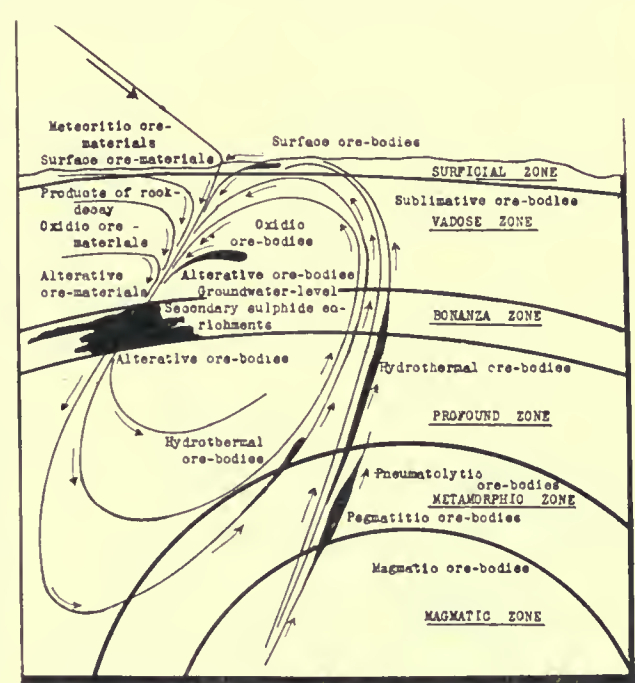

DIAGRAM SHOWING UNDERGROUND CIRCULATION OF WATER.

of metallic substances derived from each source is difficult to determine. Meteoric sources supply much larger amounts than has been commonly supposed. The part liberated by the secular decay of rocks is probably the largest. By the oxidation of small masses of sulphidic ores in rocks appreciable contributions are made. Through the constant working over of the bonanza layer, the ores are kept localized. At any rate, deposition of ores direct from the vadoses zone is much more important than is usually assumed. The conclusions may appear, at first sight, somewhat theoretical; but accord with the observed facts. Of the worked ore deposits of the world, a majority probably have their immediate origin from vadoses rather than seated igneous sources.

Time in Drilling

The following tabular recapitulation of the drilling operations in the Laramie tunnel, according to D. W. Brunton, shows that the men could not only complete a round in an 8-hour shift, but had sufficient extra time to provide for shooting missed holes or taking care of any of the minor difficulties which often arise in tunnel work.

Exhausting smoke from face.....	10 to 12 m.
Picking down roof and sides.....	5 to 10 m.
Jacking cross-bar in place.....	6 to 8 m.
Attaching drills, making hose and water connections	5 to 15 m.
Drilling from top set-up.....	3 h. to 4 h. 15 m.
Dropping horizontal bar to lower position..	15 to 20 m.
Drilling on lower set-up	1 h. to 1 h. 15 m.
Removing drills, cross-bar, hose, etc.....	15 to 20 m.
Blowing out holes, loading and firing.....	15 to 25 m.
Ignition to explosion of last hole.....	8 to 8 m.
Total time required to complete cycle of operations	5 h. 24 min. to 7 h. 28 m.

British Columbia Living Conditions

By S. S. FOWLER

[In the course of an interesting and instructive paper on costs and cost conditions at the Bluebell mine, read before the Canadian Mining Institute, Mr. Fowler gave the following details as to quarters and wages.]

The Bluebell mine is situated on a peninsula which projects from the east side of Kootenay lake, British Columbia. The orebodies, outcropping at 100 ft. or less above the water-level, are attacked through an adit whose portal is within 100 yd. of a wharf at which all supplies are received and from which all product is shipped. Adjacent to the portal are the concentration plant and shops; and the office, laboratory, and living quarters, save certain cottages, are within 200 yd. thereof, while the greatest distance from which the ore so far developed requires to be hauled does not exceed 300 yd. It will be observed, therefore, that accessibility is practically perfect. Nelson, the chief source of ordinary supplies, is distant about 32 miles by boat.

The living quarters comprise: (a) Several four-room cottages, all plastered and painted, situated about 500 yd. from the work, provided with water and electric light and each surrounded by a fenced plot of ground 60 by 120 ft. These cottages are rented to employees with families at \$12 per month each. (b) A bunk-house containing 27 rooms and two recreation rooms. All of these are plastered and painted and open on to covered verandas, there being no internal passages. No more than three men may occupy any one bedroom. (c) A 'dry'-house adjoins the bunk-house and contains in one room 6 shower-baths with cement floors and ample sinks, laundry tubs, and hot and cold water. In a connecting room are lockers properly ventilated and provided with steam-pipe below. Toilets are in a small separate but conveniently placed building and are fitted with flush closets on a cement floor. All buildings are steam heated when necessary. (d) Within 50 yd. of the bunk-house is a boarding-house with seating capacity for 100. In a basement of this building is a post-office (Riondel) and a store supplied with the common necessities of the employees; but no employee is either compelled or influenced in any way to trade there. The dining-room is ceiled, painted white, and amply lighted on north and south sides, thus being a cheerful place whose influence on the dispositions of those who use it—to say nothing of their appetites—is notably favorable. An easily accessible field situated some 300 yd. from the living quarters is much used for sports, and several of the men have maintained their own canoes and small motor-boats in the nearby bays.

Without reference to the natural and quite exceptional beauties of the surroundings, such are the conditions which affect the lives and work of those who labor at Bluebell. It need hardly be said that they attract the best class of men, who, when once they have secured employment, usually are not desirous of change. On the part of the management there has been no attempt at paternalism. The sole prohibitions are canvassing, gambling, and overmuch drink. It does nothing and provides nothing which may be regarded as charity. The result has been that while doubtless all hands realize that low costs are essential to a continuance of operation, the men as a staff also possess what may be termed a 'collective conscience,' the existence of which has contributed in large, no doubt, to low costs in a country of high wages and expensive materials.

Practically all work has been done by day labor rather than by contract, and the wages paid (regarded as 'standard' for the district) are as follows, 8 hours being the basis except for mill hands, who work 9 hours:

Foremen, \$5 to \$6; shift bosses, \$4 to \$4.50; machine miners and helpers, \$3.50; hand miners, \$3.25; mill hands, \$3 to \$4; blacksmiths and helpers, \$3.50 to \$4; compressor runners, \$4; muckers, \$3; carpenters and machinists, 50c. per hour; outside laborers, \$3. The approximate average wage for all classes is \$0.433 per hour.

Western Australian Gold Production

The gold yield from Western Australia in March was valued at \$1,975,000. The mint dealt with 114,405 oz. of bullion and issued \$590,000 in gold coin. Returns from the chief producers were as follows:

Name.	Tonnage.	Value.	Profit.
Associated	10,858	\$ 70,500	\$ 5,600
Associated Northern Blocks.	1,988	28,000	5,000
Burbanks Main Lode.....	1,770	21,500	10,000
Golden Horse-Shoe	25,201	162,000	6,500
Golden Ridge	2,982	26,500	8,700
Great Boulder Perseverance.	19,715	105,000	5,800
Great Boulder Proprietary..	18,057	238,000	131,000
Great Fingall	5,929	58,500	6,500
Hainault	5,700	35,000	2,500
Ivanhoe	20,010	208,000	90,000
Kalgurli	10,720	107,500	45,500
Lake View & Star.....	18,202	106,500	18,000
Oroya Black Range.....	4,750	40,200	10,000
Oroyo Links	11,030	67,500	15,000
Sons of Gwalia.....	12,740	98,500	20,000
Sons of Gwalia South.....	2,435	11,500
South Kalgurli	9,668	61,500	10,500

Calumet & Hecla Report

THE report of the Calumet & Hecla Mining Co. just issued covers the period from April 30 to December 31, 1911. A comparison is made of mining costs, yield of the ore in pounds of copper for a period of four years. This report is interesting in connection with similar reports just issued by copper companies operating on low-grade deposits in Utah and Arizona.

CALUMET & HECLA LODE

	1908.	1909.	1910.	1911.
Tons mined	2,643,938	2,842,880	2,795,514	2,909,972
Mine cost per ton..	\$2.15	\$1.93	\$1.92	\$1.84
Pounds of copper				
per ton of rock..	31.22	28.18	25.77	25.47
Total cost of copper				
per pound, cents.	9.00	8.28	8.96	8.52

This tonnage is produced from the so-called Conglomerate lode, and the Oseeola lode, two-thirds of the output coming from shafts on the former lode.

The results of the operations of the re-crushing plant started in February 1909 for the re-treatment of tailing from the old Calumet mill are also given.

	1909.	1910.	1911.
Tons coarse tailing crushed....	278,175	441,920	447,794
Pounds copper in material.....	12.96	12.60	12.66
Pounds copper saved.....	4.50	4.42	4.50
Cost per pound, exclusive of			
smelting and selling, cents....	4.81	5.08	5.01

Dividends

Alaska United G. M. Co., dividend No. 19, 50c. per share, payable May 28.

Alaska Mexican G. M. Co., dividend No. 66, 40c. per share, payable May 28.

Alaska Treadwell G. M. Co., dividend No. 97, 75c. per share, payable May 28.

The Pittsburg-Idaho Mining Co., of Gilmore, Idaho, has declared a dividend of 4c. per share.

The Parrot Silver & Copper Mining Co. has declared a regular quarterly dividend of 15c. per share, payable May 27.

The National Lead Co. will pay a regular quarterly dividend of 1 3/4% on preferred stock, payable June 15.

The National Lead Co. will pay a regular quarterly dividend of 3/4% on the common stock June 29.

Discussion

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Insertion of any contribution is determined by its probable interest to the readers of this journal.

Mining on the West Coast of Mexico

The Editor:

Sir—My attention is called to your issue of May 18, in which you make the statement that only the Mina Mexico and the La Dura mines are working in the Yaqui River district. This is an error. The following mines are working at the present time and there has been no thought of their shutting down and no diminution of their output:

The Goteras, Thomas C. Hardy, consulting engineer and manager; the Las Animas, Wyman Mining Co., W. C. Laughlin, lessee and manager; the San Antonio Copper Co., J. E. McIntyre, superintendent; Mina Mexico, W. E. Pomeroy, manager. In addition to these four, there is another mine in the San Xavier district under the management of J. A. King. I do not recall the name either of the property or the company.

You are also in error in stating that the Southern Pacific railroad has suspended service on account of the depredations of the Yaqui Indians. There were a few bridges burned more than a month ago between Guaymas and the Yaqui river, and service was suspended only until these could be repaired. On account of the depredations of the *Revolutos* in Sinaloa, service was temporarily suspended south of San Blas. It has not yet been resumed fully, but the company is operating some trains now on the south end.

For your further information regarding industrial conditions on the West Coast, I may add that the exports of citrus fruit from Sonora this season show an increase of more than 30% over last year. The exports of tomatoes and cantaloupes show an increase of 50% over last year.

G. C. WHITE.

Guaymas, May 23.

[It is always a pleasure to correct bad news, and we are sincerely glad that conditions in Mexico were never as bad as reported and are now much better. Steady improvement is, in the opinion of competent observers, to be expected from now on. A country that increases its agricultural exports in the midst of revolution, is evidently sound at heart, and the 'West Coast' may well anticipate generous prosperity when the present troubles are finally ended.—EDITOR.]

Low Mining Costs

The Editor:

Sir—I am sure the readers of your journal would be interested in the record made for April at Prietas, Sonora, Mexico, at the mines of the Mines Company of America. The ore was taken from the Creston and Colorado mines. A total of 18,000 tons was treated in two mills: 9900 tons in the Creston mill and 8100 tons in the Grand Central mill of Charles Butters & Co., Ltd. This was done at a total mining and milling cost of \$2.60 gold. The divided costs were as follows:

Mining and development	\$0.65
Tramway	0.07
Milling	0.45
Cyaniding	0.97
General expenses	0.23
Bullion	0.20
Taxes	0.03
Total cost	\$2.60

I think this is a record for low costs in Mexico, remembering that it was done during the disturbed period of last

month. These low costs were obtained notwithstanding the fact that power costs in the neighborhood of \$12 per horse-power.

M. F. Perry, joint manager for the Mines Company of America and Charles Butters & Co., Ltd., is in charge of the property, and I think that a great deal of credit is due him and his staff for such a low record of working costs.

CHAS. BUTTERS.

Oakland, California, May 24.

American and Foreign Technical Journals

The Editor:

Sir—In your issue of December 9, 1911, in a book review by T. T. R., appeared the following:

"That American text-books and technical journals are ample to meet the needs of the well-read metallurgist is far from the truth, is exhibited by the fact that there does not exist in America a metallurgical journal to be compared with *Metallurgie*."

Supposing that T. T. R. is right (which he ought to be, having had such experience as would make him a judge), then there is only one inevitable conclusion, which is, that something is wrong with American technical journals. The purpose of a technical journal, as generally understood, is to keep its readers well informed on the best technical practice and at the same time make money for its owners. The latter usually follows if the first is accomplished. Does T. T. R. mean to tell us that the metallurgist who doesn't read *Metallurgie* because he can't read French cannot be well informed? If so, then why doesn't he or the journal with which he is connected endeavor to remedy the matter? I have often wondered how much American engineers were missing and how often they duplicated the improvements and progress of foreign engineers on account of their inability to read French or German. According to T. T. R., it must be considerable.

What is to prevent American periodicals from translating and publishing these articles for us in English? True, *The Mining Magazine* abstracts some of the better articles, but there are others that must have unquestionable value. *The Mining and Scientific Press* and other technical periodicals print pages from the U. S. G. S. bulletins and other publications in English which, I feel sure, the majority of readers would appreciate more if they were filled with translations of the better foreign articles.

In this day of indexes, digests, etc., we can easily find all the information published in English, but the technical information in a foreign language, even when found, is a sealed book to 95% of our engineers. A reader cares little whether an article is original with the publication printing it as long as he is unable to read it elsewhere. Why can not or will not a technical journal adopt the policy of translating and reprinting such articles in foreign publications that possess as much merit as the average run of their own articles? Are there too many of them? If so, then give us a special department of several pages filled with the best. Are we already getting in English those worth while? If so, then T. T. R. is wrong, and he put it rather strongly.

NOAH'S ARK.

Guazapares, Chihuahua, May 3.

[Our correspondent, like any other person who amplifies a specific statement into a generalization, produces some confusion of ideas. The statement which he quotes was used to refute an assertion that the author of a text-book may properly confine his references to a few of the American technical journals and the standard American treatises on metallurgy. The patriotism of this is more admirable than its accuracy, for the best work upon the mechanical treatment of steel, for example, is an English book, and, as quoted, *Metallurgie* (a German journal, by the way) is in a class by itself in many respects. It does not follow, however, that those who do not subscribe to foreign technical journals are missing much that would

be of value to them. All the more important volumes in French and German are promptly translated into English with a view to reaching the large group of readers in America who buy technical books much more freely than do English engineers. The American Chemical Society maintains a staff of over 200 editors and abstractors whose duty it is to read and abstract all the important papers bearing on chemistry as they appear, and over 6000 such abstracts were published in *Chemical Abstracts* during the first four months of the current year. All phases of engineering work are based upon either physics or chemistry, and as the chemical side is the one that lends itself easiest to investigation, it is safe to say more than half of the important papers published abroad are thus abstracted. The labor and cost of this work is enormous, and it would be idle for any other American journal to duplicate it. Important papers without bearing on chemistry appear abroad, but they are usually on topics such as coal or iron mining, or descriptive and areal geology, which either are outside the field which the *Mining and Scientific Press* attempts to cover or would not interest Americans. Abstracts of the few papers which are not included in any of these groups appear in our columns from time to time. The few men who are engaged in advanced research work must necessarily consult all the literature on the topic under investigation, but those engaged in such work can usually read foreign languages, though perhaps with difficulty. It must not be overlooked that technical journals confine themselves to some special field; the *Mining and Scientific Press*, for example, is not a bibliotheca, but a journal devoted to the mining and metallurgy of the non-ferrous metals, and many important articles which would be of interest to a few readers have to be excluded to make room for what interests the majority. We would be glad to receive expressions of opinion and suggestions from all our readers as to how we can best serve their needs.—THOMAS T. READ.]

Conservation v. Encouragement

The Editor:

Sir—Just before the assassination of that great and good man, Abraham Lincoln, Schuyler Colfax left Washington to cross the continent. As Mr. Lincoln bade him farewell, he said:

"I want you to make a speech for me to the miners you may find on your journey. I have very large ideas of the mineral wealth of our Nation. I believe it is practically inexhaustible. It abounds all over the Western country, from the Rocky Mountains to the Pacific, and its development has scarcely commenced. Now the Rebellion is over and we know pretty nearly the amount of our national debt; the more gold and silver we mine makes the payment of that debt much easier. I am going to encourage that in every way. We shall have hundreds of thousands of disbanded soldiers, and many have feared that their return home in such great numbers might paralyze industry by suddenly furnishing a greater supply of laborers than there will be demand for. I am going to try to attract them to the hidden wealth of our mountain ranges, where there is room for all. Immigration, which even the war has not stopped, will land upon our shores hundreds of thousands more every year from overcrowded Europe. I intend to point them to the gold and silver that waits for them in the West. Tell the miners for me that I shall promote their interest to the utmost of my ability, because their prosperity is the prosperity of the Nation. We shall prove in a very few years that we are indeed the treasury of the world." This was the last message, almost the last public utterance, that came from the lips of Mr. Lincoln. Those prophetic words, uttered nearly half a century ago, still make the heart of a miner glow. How different from the 'encouragement' the miner and prospector receives from a paternal and beneficial government at the present time.

The purchase of Alaska is generally accredited to the far-seeing enterprise of W. H. Seward, Secretary of State

under Lincoln, and afterward under Andrew Johnson, but is it not possible that this purchase was inspired by the wisdom of Lincoln? At any rate, on March 30, 1867, the transfer of 581,107 sq. mi. was made to the United States for the sum of \$7,200,000, known as Russia-America-Alaska; on June 20, 1867, ratifications were exchanged, and the formal transfer made to General Rousseau at Sitka, October 9, 1867. At that time there was much dissatisfaction expressed all over the country at this high expenditure of public money "for this miserable barren waste of ice and snow."

Forty-four years have come and gone since that time, and it is now evident that Mr. Seward made no mistake; that before even one-fourth of this vast region has been even partly explored, and only a few thousand acres surveyed, Alaska has returned her purchase price many times over. This "miserable barren waste of ice and snow" has since 1880 yielded a mineral production of \$186,000,000, out of which \$179,000,000 is represented by the value of the gold output. Since the year 1800, about 3,000,000 sq. mi. have been added to American territory at a cost of approximately \$90,000,000, all of which the output of American gold for almost any one year since 1900 more than paid for. Mr. Lincoln's prophecy has been well sustained.

Not so long ago some wise 'wags' even attempted to create an overproduction-of-gold scare, but the rapid increase in the production of gold and silver of a few years ago has ceased. It is a safe prediction that, under the present system, in a few years the pendulum will swing in the opposite direction; at least so far as the United States is concerned. The present standard of the gold and silver production in America is maintained by application of improved metallurgical methods to low-grade ores and dumps at old mines, material which was previously considered unprofitable, and not by virtue of new discoveries. It is not hard to see the 'beginning of the end' of the large gold and silver output in this country, if the Government persists in 'conserving' the unexplored mineral districts for some distant future generation.

It is said that it is far from being the intention of prohibiting "legitimate settling and prospecting"; contrariwise, the Government's desire is to encourage it; but the fact remains that all prospecting and exploring has practically ceased throughout the entire mountain regions of the West; the old-time hardy, intrepid, and intelligent prospector has been driven out of the field. If you ask him why, he will likely tell you that he does not propose to be bulldozed by some impertinent Forest Ranger, who knows less about minerals than the horse he rides, nor to take dictation from him as to where he may or may not prospect.

The prospector does not object to inclusion of mineral areas in the National Forests. The average prospector has more regard for the timber on his claim than has the Government itself; he is a conservationist by instinct; but he does object to the intolerable restrictions to which he is subjected, and he has quit the field in disgust. There is something radically wrong with the system as now in practice, especially with reference to the unexplored mineral areas in the western states. Would it not be far better to leave each state to work out its own "conservation" to suit its own peculiar needs? Anyway, encourage and protect the pioneer settler and prospector.

MARTIN FISHBACK.

El Paso, Texas, May 1.

ZINC to the amount of 71,937 tons, equal to 25.1% of the total production of primary spelter, was derived from secondary sources in the United States in 1911, according to J. P. Dunlap of the U. S. Geological Survey. The zinc recovered in alloys other than brass amounted to 3223 tons. Of the 44,714 tons of secondary zinc recovered as spelter, 18,244 tons was obtained by re-distillation from drosses and skimmings. In addition to the large quantity of spelter recovered, several thousand tons of zinc chloride was made from drosses, skimmings, and similar material.

BOSTON

COPPER METAL STRONG.—DIVIDENDS INCREASE.—NEW LIFE FOR SHANNON.—AMSTER PLANS NEW COMPANY.

The copper metal has advanced in price faster than the stock market for the shares. Some of the producing companies have increased their dividend rates, and the public is expected to bid up good copper stocks in anticipation of the increased earnings inducing other companies to distribute larger profits to shareholders. Calumet & Hecla and Quincy have both added to their fame as dividend payers by increasing their rates. These two Lake coppers have probably done more than any other companies to inspire public confidence in the stability of the mining industry as a source of dividends, and it is regarded as particularly fitting that at this crisis they should help set the pace for the other dividend-paying copper companies. Quincy is an older dividend-payer than Calumet & Hecla, and has maintained payments since 1862, except for the two years 1866 and 1867. The company was incorporated in 1848. Under the Michigan laws, a charter could be obtained for only 30 years. So Quincy has had to reincorporate twice. Its first capitalization was \$500,000 in 1848; its second was \$1,000,000 in 1878, which was increased to \$1,250,000 in 1889, \$2,500,000 in 1896, and \$3,750,000 in 1906. In 1908 its third term of life was entered without further increase in capitalization. Calumet & Hecla was organized in 1871 with a capital of \$2,500,000 and reincorporated in 1900, but has retained its original capitalization since the formation of the company. Under the new laws of Michigan, in 1905 its charter was amended so as to make it a holding as well as a mining and smelting company. Last year the company sought to have its capitalization increased to \$10,000,000 for the purpose of effecting a merger among a number of companies in the Lake country, but after a close and acrid contest the proposal was dropped. Calumet & Hecla leads Quincy in the total amount of dividends paid, and is now on a basis of \$40 per year, with Quincy paying \$5 per year. In addition to these two well established companies, Ahmeek, Amalgamated, North Butte, and Old Dominion have increased their rates. Last year there was but one increase, a really unexpected and remarkable one, by Old Dominion, while four companies, Calumet & Hecla, Copper Range, Mohawk, and Osceola reduced their rate, and two other small but formerly rich copper properties, Butte-Ballaklava and Shattuck-Arizona, discontinued payment. There are now 15 regular dividend-paying coppers on the Boston Exchange, as compared with 17 a year ago, 20 in 1910, 15 in 1909 and 1908. Other companies are expected to follow the lead of the stronger stocks and by declaring dividends attract the public back into the copper market, with as lively an interest as in 1906.

Nathan L. Amster, one of Boston's copper speculators, is still looking for his money where he lost it. Instead of withdrawing his losses, Mr. Amster declares that his hat is still in the ring. He has lost the control of the Arizona Commercial, but has held on to Shannon and to Boston & Corbin. Shannon is now producing at the rate of 18,000,000 lb. of copper per year, a material increase over last year. As a commentary on the changing methods of mining since churn-drills and steam-shovels were introduced from the iron districts, Mr. Amster claims Shannon to have been the first porphyry mine ever opened, and that the management would consider the advisability of changing the method of mining to open-cut but for the expense involved in the purchase of steam-shovels and in other necessary changes in machinery. Shannon has produced over 100,000,000 lb. of copper since the mine was declared exhausted a few years ago, and is now said to be in better shape than ever. Mr. Amster points to this fact as the best possible evidence of the great value of churn-drilling. Its application to Shannon earlier in the history of the company would have kept hundreds of investors

from sacrificing their holdings a few years ago, under the belief that the mine had played out. The Shannon ore deposit is spread out laterally, and when the lower limit of the blanket was reached the mine was considered exhausted. The time may come when drilling will be applied to all properties in the neighborhood of rich producers which have been abandoned, and in the future no mining property will be given up for lost until every modern method of finding extension of orebodies is exhausted. It is of interest to note that Amster has taken over a new copper in the Patagonia district of Arizona, 62 miles south of Tucson, but only three miles from the Southern Pacific railroad. He claims to have in this property an orebody similar to Miami and Chino, 800 to 1000 ft. wide and 5000 to 6000 ft. long. The property will be developed by the open-cut method, and rich ore which it is claimed exists in shoots will be shipped to the Copper Queen smelter at Douglas and to El Paso. This mine has not been incorporated as yet, but Amster is known as a skilful mining operator and a daring market manipulator, and should he decide to organize a company to operate his new property he should have little difficulty in commanding the support of a large following among both Jews and Gentiles in Boston and New England.

WESTERN AUSTRALIA

PRODUCTION.—THE STRIKE.—RAILWAY CONSTRUCTION.

In March two new producers, the Ywanni and Mountain Queen, returned 3050 tons worth \$49,000, and 3516 tons worth \$15,300, respectively. The former has a 20-stamp mill, tube-mills, and vacuum plant, while the latter is so far equipped with two Holman pneumatic stamps. On running time the Holman stamps crushed 67 tons each per day. About the most important development during the month was at the 200-ft. level of the Kalgurli, where, in the V drift off W cross-cut the ore is 24 ft. wide and worth \$27 per ton. In the S drift off this cross-cut the first 9 ft. assays \$30, the next 5 ft. \$12, and the next 10 ft. \$5 per ton. The Lancefield, at No. 8 level, cut the lode, and so far it is 96 in. wide and worth \$11.30 per ton. The Sons of Gwalia progress reports are fairly good; diamond-drilling is still in progress on three levels. The Pingall winzes below 17 and 18 levels show profitable ore. Reports from the Bullfinch, Ywanni, Lake View & Star, and numerous other properties are on the whole rather satisfactory.

Ore of low grade shows at the north end of the Kalgourlie field. The Golden Dream treated during the past half-year 7204 tons of oxidized ore with a yield of \$18,000, or \$2.48 per ton. The reserves are stated at 7000 tons, worth \$2.62, in lodes 15 to 30 ft. wide, assaying \$1.80 to \$2.64. Dividends are paid on this grade. The treatment plant includes a jaw-breaker, a 5-ft. Huntington mill, sundry pumps driven by a Crossley gas-engine, spitzkasten, and leaching vats for the sand. The summer is over, and we have had splendid rain, so that many ponds are full, rock holes filled, and grass is shooting up fast.

The Iron and Brass Molders' strike is still on, with no apparent settlement in view, yet the mines are working full time on spares and makeshifts. The men have no chance of getting \$26 weekly and extra overtime.

Preparations are in progress for the starting of work on the trans-Australian railroad. In all probability the workshops will be erected in Kalgoorlie near our own central station. It is the intention of the federal government to supply the men with stores, look after sanitary condition of camps, and work everything on a proper system. The work will be done by day labor. The Western Australian Government has decided to sell water at 48c. per 1000 gal. to mines not yielding over \$2.40 per ton; and the old price of 84c. to those returning up to \$3.26. This is a big concession, and may stimulate work. On March 21 there was a fearful cyclone or 'cock-eye' on the northwest coast, in which a 4000-ton steamer and 140 passengers and crew disappeared, besides which smaller craft were wrecked, many lives lost, and great damage done generally.

Every year these disturbances occur in that region. We have modified 'blows' on the goldfields, but nothing approaching those in the tropics. There have been a few mining accidents of late, also several 'high-grading' cases. Metallurgically there is little to report. A party is about to re-treat the residue from the old Boulder Main Reef dry-crushing and roasting plant, by a system of leaching. A few years ago another syndicate sought to re-treat this dump by agitation and filter-pressing, but failed badly, the expected gold content not being recovered. The Boulder has its second Ridgway, No. 3 type filter, at work, the first type being discarded. One man can watch several of these working, with a minimum of repair. Extraction and cost are said to be good.

ST. PETERSBURG, RUSSIA

OSMIRIDIUM IN THE URALS.—SILVER IN THE URALS.—GOLD ALONG THE AMUR.—MINERAL DEPOSITS OF KUZNETZKY.

The production of osmiridium in the Urals has fallen almost to the vanishing point, according to the returns issued for 1911. In 1902 the production amounted to 11 funts, but it has declined since 1904 with fair regularity to only 34 zolotniks last year, after having been 3 funts 93 zolotniks in the year 1910. It is a remarkable decline, particularly at a period when the Russian Government is arranging to monopolize the platinum production with, among other objects in view, the retention in the country of the

silver are extracted from ores and smelter products abroad, and it is on the assumption that the results from these equaled those of 1910 that the 500 poods total for 1911 is arrived at. This would make a record silver production for the Urals.

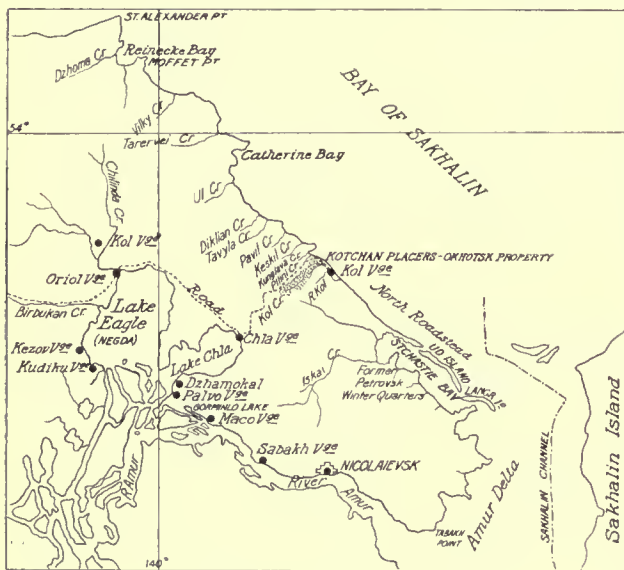

Reports have been received from Nikolaievsk as to the prospects for gold working on the Amur during the coming open season, and it is stated the gold deposits there will be vigorously worked with electric dredges; particularly on the ground of the Ochotsk company, which has been leased to the English Orsk concern, a station having been built about 12 versts (8 miles) from the mines on the bank of Lake Chlya. Considerable activity is observable also on the gold-bearing Lakes Udy and Orel, and negotiations are said to be proceeding between the present holders and English houses for the transfer or sale of the properties. With the institution of such work and thereafter of exploitation, Nikolaievsk, which is now of considerable significance as a port and centre of the fishing industry, will acquire importance also as the centre of the gold industry on the Lower Amur. A group of gentlemen have asked for permission of the Irkutsk mining government to explore and exploit the rock-salt deposits within the limits of its administration. The personnel of this group, it is added, is exclusively Russian.

In the foothills of the Altai mineral deposits occur, particularly in the Kuznetzky district, which contain gold, silver, copper, iron, and coal. The most important of these are gold and silver, though the Kuznetzky is rich in coal measures and beds of iron ore. Between the Salairsky and Kuznetzky chain of hills there are frequent outcrops of coal covering an area of about 60,000 square versts, in some cases to 20 sagues or 140 ft. thick. Some of the deposits yield good coking coal. Altogether the district is considered to be very valuable. Along with the coal there is iron ore. To the north along the Salairsky chain there is both red and brown iron ore, and to the south along the river Telbess and near the tent of Sucharinki magnetic iron ore occurs in large amounts.

LONDON

TIN COMPANIES.—METHODS OF FINANCING.

I have repeatedly referred in this column to the unsuccessful work done by the Schiff-Dietzsch group in Cornwall. One flamboyant scheme has succeeded another, and large sums of money are extracted from the public, but no tangible results are ever obtained. The latest of the scheme was the St. Agnes Consolidated. To avoid newspaper criticism, the shareholders' meetings are kept quiet, but nevertheless the reports come to my notice. For instance, one was issued early in May and it affords as good an example of exaggerated optimism as I have seen for a long time. It refers to the fact that the company's operations have been almost entirely confined to the development of its extensive mining area at St. Agnes, and says that "these operations have been effected with highly satisfactory results." No one acquainted with the results actually attained would endorse this statement. It is common knowledge that the West Kitty Mines, in which the company holds a controlling interest, is in a tight corner, and, without a good deal more capital, cannot possibly be made a profitable proposition; the valuable lode found some months ago in the 80-ft. cross-cut south from Wheal Friendly cannot be properly developed until the shaft has been sunk another 25 fathoms. At East Blue Hills, the only other property to which much attention has been given, a fair amount of low-grade ore has been exposed and most of it already milled. But it is hardly correct to call this ore "an excellent tin deposit", or to assert that, because the lode presumably enters the adjoining Blue Hills mine, "a large block of ground for extensive mining operations" is available. The St. Agnes district is notorious for the bunchiness of its ore, and any forecasts of the contents of undeveloped ground are the merest guesswork. No doubt the company owns properties of great possibilities, and the limited exploration so far undertaken has

LOWER AMUR GOLD REGION.

associated osmiridium; it being a matter of perennial complaint in Russia that this precious metal leaves the country practically in the form of a free gift to the buyers of the platinum ore. It is not to be supposed that though the production has practically ceased in the Urals the metal has ceased to be associated with the platinum which is still found in fairly large quantities in that area. The presumption is that the St. Petersburg or local refiners have not found it to pay to separate the osmiridium, and that now produced is obtained at the refineries of western Europe and America.

The record of last year's silver production in the Urals shows that progress is being made in its production. It is estimated that the production for 1911 in the Urals amounted to about 500 poods, as compared to 452 poods produced in 1909. The works engaged in separating this metal are those of the Kyshtim company and of A. Ph. Poklieffsky-Kozel, in the Northern Ekaterinburg mining district, which produced the small quantity of 9 poods 14 funts. But in the Western Ekaterinburg district at the Nizhni Kyshtim electrolytic works 117p. 8f. of pure silver was separated. It is stated that besides the silver produced at the Blagodat mines of Poklieffsky-Kozel in the process of smelting copper and lead ores, both gold and

given encouraging results. This is really all that can be said. The capital of the company is £175,000, and of this £137,900 has been issued; with the exception of about £400, this has been allotted for the purchase of properties which at the time consisted solely of leases, and none of the properties had any equipment. Cash capital to the extent of £43,700 was obtained by the issue of 6% participating debentures. The expenditure from the commencement of operations to December 31 last has been:

On plant, shafts, and buildings.....	£ 9,373
On development and establishment expenses	£10,690
Less tin sales, interest, etc.....	2,078
	8,612
On investments in and loans to West Kitty Mines	23,502
On preliminary expenses and commission on placing bonds	2,364
	£43,851

"Sundry debtors" and cash in hand amount to £1728, while the "sundry creditors" are £11,543; so it is evident that the company is in debt and will require additional capital to keep it going. Of the £10,690 placed to development account, apparently only £3174 was actually spent on the mines.

After writing the above paragraph, it is pleasant to be able to turn to the doings of another tin company that is managed economically and wisely. I refer to the Tekka, which belongs to the Wickett group, operating alluvial tin mines in the Federated Malay States. The offices are in Redruth, and the directors and shareholders are mostly Cornishmen. Osborne & Chappel are the managers. During the year ended January 31 last, 625,844 cu. yd. of gravel was treated, yielding 419 tons of black tin, a recovery of approximately 2 lb. per cubic yard. The quantity of gravel treated was 197,028 cu. yd. less than in the previous year, and the yield 14.7 tons less. Owing, however, to the advance in the price of tin, the income was £6453 greater, the figure being £46,599. The mining cost was £13,620, and income tax absorbed £1057. The expenses in England were £560. The divisible profit was £32,276, out of which £26,741 has been distributed as dividend, being at the rate of 35%. The smaller amount of gravel treated is explained by the fact that more water is now required for elevating purposes. During the year the Taping property has been acquired, and work was started in December.

A great deal has been heard of Nigerian tin recently, and the speculation has been ridiculous and wild. Not only so, but we have been treated to wide differences of opinion on the part of the mining engineers. The spectacle is unedifying and I pass it by. Instead I will give an account of actual work at the Bisiehi, which is a small alluvial property near Naraguta, in the Bauchi province. The company was formed in October 1910, and H. W. Laws is consulting engineer. The property is favorably situated as regards water-supply and fall, and hydraulic mining has been adopted for most of the ground. Until the end of March the work had been confined to ground-sluicing and calabashing. The report from the foundation of the company to December 31 last shows that 171½ tons of concentrate had been won. Of this, 106 tons has been sold for £138 per ton, the assay being 73.3% metal. The remaining 65 tons in transit when the accounts were prepared has since been received and sold. The cost of production and freight to Liverpool, but not including cost of treatment, was £49 per ton of concentrate. The accounts show £17,315 as the receipts, actual and estimated, from the sale of the 171½ tons, after all charges for freight had been paid. The cost of mining was £8846, and London expenditure accounted for £2768. The net profit was £6490, which was carried forward. Since the beginning of the year, the production at the mine has been 60 tons, which is lower than the average. The reason is that the labor force is scarce and men have been taken from the ground-sluicing operations to help in the erection of the hydraulic plant.

JOHANNESBURG, TRANSVAAL

RECORD OUTPUT IN MARCH.—POSSIBILITY OF EXCEEDING IT.
—WORK OF THE THREE LEADING PLANTS.

A record gold output was declared by the Chamber of Mines for March, amounting for the whole of the Transvaal to 830,723 oz., of a value of £3,528,688. This is easily a record, the previous highest month, being January, with a declared output of the value of £3,130,830. Unfortunately, neither of these declared outputs was actually produced during the month to which it is credited, the output for March as declared including £297,946 worth of gold accumulated in previous months to make the monthly output uniform and amounting to 70,143 oz., while January also included accumulated gold reserves to the extent of £82,564. Nevertheless, if gold reserves are excluded and only actual production considered, the output for March is still a record one, as it amounts to no less than £3,100,361, being 163,220 in excess of that for November, the previous highest month for gold actually produced. The abolition of gold reserves by most of the companies and their inclusion in the March output places the record at a figure which some doubt will ever be exceeded. This doubt is based largely on the chronic scarcity of labor on the Rand and to the fact that several large producers are practically worked out, such as the Geldenhuis Estate, May Consolidated, and Crown Reef, while the New Primrose, Ferreira, Village Main, and other prominent producers may also soon follow in their wake. It is quite true, however, that such new producers as Brakpan, Bantjes, City Deep, and Roodepoort United can materially increase their output under more favorable labor conditions, and so can the Robinson Deep, Crown Mines, and Randfontein, as well as some of the low-grade deeps near Germiston. But so much of the Rand has been put under tribute and so much of the richer ores worked out, that even if full credit be taken for the half-dozen developing properties not yet producers in the Far East Rand, a monthly output of over three and a half million sterling as declared for March will not be easily surpassed. With favorable labor conditions the output of the Rand will exceed three million sterling monthly. For some time to come increases in production may be expected, but the abolition of the gold reserves may cause the records of individual companies to fluctuate more than has been the case.

Only three producers on the Rand working under normal conditions declared a reduced output for the month of March, the most interesting feature perhaps being the return of the East Rand Proprietary Mines to the top of the list of producers after a somewhat prolonged absence under the influence of peculiar conditions. The East Rand Proprietary Mines, with its equipment of 820 stamps and 25 tube-mills, crushed 163,000 tons, with a recovery of 66,147 oz., valued at £280,975, indicating a recovery of over 8 dwt., where, according to the annual report of the superintending engineer, the average value of the ore reserves is only 6.9 dwt. No official explanation has, up to the time of writing, been given of this unexpectedly high yield, but the local mining press, usually well informed on these questions, attributes it to increased sorting, cleaner mining widths, and sending less development rock to the mill. Last year little development was accomplished, and last month the percentage of waste rock sorted out was under 10%, so that some other explanation will have to be found for the abnormally high yield. At the Randfontein property, which came next on the list, some 229,642 tons was crushed, yielding £260,615, being at the rate of 22s. 9d., or practically 5½ dwt. per ton, as against over 8 dwt. at the East Rand Proprietary Mines, where the ore reserves are supposed to be the same grade. No one would expect the East Rand Proprietary Mines to approach the yield of the Crown Mines, which come next on the list. During March 161,500 tons was crushed, yielding £257,884, or 31s. per ton; while in March the recovery at the East Rand Proprietary Mines averaged 34s. per ton milled.

NEW YORK

COPPER MARKET QUIET.—MICHIGAN COPPERS INCREASE DIVIDENDS.—ANACONDA HAS LARGE CASH SURPLUS.—TENNESSEE COPPER.

There is still to be heard some little argument in regard to the copper surplus, and there remains a little skepticism as to the manner in which the world's supply—which at one time seemed to threaten the future of the industry—disappeared so rapidly under skillful handling. It is pointed out that the semi-official figures that are given out treat only of refining outputs, and that this may not by any means represent all of the mine output. Inasmuch, however, as the mine output is not commercial copper until it has gone through the refinery, it is not unfair to say that it is the amount of refined copper that is ready for sale in which the consumer is interested. It is refined copper that goes to the consumer, and he is justified in studying mine outputs in something the same light as he would ore reserves, since both are convertible into commercial copper.

The Calumet & Hecla is admitting its stockholders to their share of the prosperity resulting from higher priced copper. The dividend declared last week was for \$10, as compared with \$8 three months ago, and \$6 six months ago. The Calumet & Hecla directors are calling in \$1,000,000 of the ten-year 5% notes which the company put out in 1909. There is one feature in connection with the Lake coppers that is worthy of mention. These companies do not suffer from an overload of capitalization. The result is plainly to be seen from the following that the Lake coppers have in Boston, where conservatism is one of the prized traditions. The report of the Calumet & Hecla Co. sent out last week covers the period from April 30 to December 31, 1911, the company's fiscal year having been changed to agree with the calendar year. During eight months there was produced 74,130,977 lb. of copper, as compared with 72,059,545 in 1910. The average price received for copper was 12.82, against 13.20 in 1910; copper cost of 8.52c., against 8.96c. in the previous year. The Quincy Mining Co. is another of the Lake coppers that has increased its regular disbursement. The current dividend just declared is for \$1.25 per share, this being an increase of 25c. over the regular dividend rate, which has been \$1. maintained since December 1910.

The financial situation of the Anaconda, Amalgamated, United Metals Selling Co. combination is worthy of some comment. The Anaconda company is now producing copper at the rate of something above 300,000,000 lb. per year, with some 1,000,000 oz. silver per month as a by-product, which, credited to copper costs, makes a material reduction. Anaconda's copper is now estimated to cost just about 9c. The Amalgamated Copper Co. owns approximately two shares of Anaconda for each share of stock outstanding. If the Amalgamated Copper Co. held no other interests, the ratio of price as between the two would be 2 to 1. The Amalgamated has, however, some other important holdings, chief among which is the capital stock of the United Metals Selling Co., long known as the largest copper brokerage concern in the world. The United Metals Selling Co. has paid 20% annually for several years, and not long ago paid an extra dividend of 50%. Its earnings are said now to be as large as at any time in its previous history. All three of these concerns now have cash surpluses that are important elements in the copper market. Amalgamated has about eighteen and one-half millions, Anaconda about three millions, United Metals Selling Co. about six millions. According to most recent reports this total of between twenty-seven and twenty-eight millions has been materially augmented during the six months last past, and it is safe to say that directors of these companies, from these sources alone, can direct the weight of at least thirty-five millions when they desire to do so, a factor of no little importance in market operations.

It is expected that the Tennessee Copper Co. will increase its dividend when the meeting of the board of directors occurs next week. Earnings have been very much

increased and a portion of the board is known to favor a distribution of part of the increased profits. The Butte-Alex Scott Copper Co. sought its Eastern market in Pittsburgh, and until recently was one of the active features on the Pittsburgh Stock Exchange. Last week the issue was stricken from the list because of the non-compliance to the rule requiring the maintaining of a transfer office in Pittsburgh. The old Blair property in Nevada, more recently known as the Pittsburgh Silver Peak Gold Mining Co., headed by William Flinn, of Pittsburgh, divided its surplus and paid an initial dividend of 16%, payable July 1. The amount required to pay the dividend is approximately \$450,000.

At the recent meeting of the Tonopah Extension Mining Co., stockholders were informed that dividends would probably be declared in July. The Butte & Superior Co., of Butte is about to install a hoist, similar to the one put in by the Tuolumne Copper Co. The hoisting plant of the latter company is now in full commission and last week the Tuolumne made its record output for one day, hoisting and sending to the smelter 400 tons of first-class ore. The Butte & Superior Co. has been growing in public favor in the East, and the shareholders apparently feel that their long patience will eventually be richly rewarded.

The end of the boom appears to have arrived, or if not arrived, at least to be clearly in sight at Porcupine. Some of the recent travelers returning thence report a condition bordering an actual physical distress. Men have been forced to abandon wives and families in an attempt to secure a 'stake' elsewhere, and in not a few cases these have come to actual want before they could be sent for. Under these conditions it is hardly possible to expect anything in the way of market features from the camp.

JOPLIN, MISSOURI

RECORD PRICE FOR ZINC.—MINES RESUMING.—TAILING TREATMENT.—WAGES RAISES.—BARYTES ORES.

Ore from the Big Western mine sold for \$61.65 in May. This is the highest price ever paid for zinc ore in the United States. The previous high figure, \$60, paid in 1905, was only maintained for a few weeks, but the present market conditions are good, with no prospects of a slump. The present production of the Missouri, Kansas, and Oklahoma districts is 5500 tons of blende, 400 tons of calamine, and 900 tons of galena per week.

Southwest of Joplin, the Gordon Hollow camp is now producing 150 tons of concentrate per week, after several unproductive years. A large custom mill handles the bulk of the tonnage, although two small individual plants are worked. At Spring City the Birthday Mining Co. has erected a modern concentrating plant which will be able to treat profitably the calamine ores with 40% zinc which come from this camp. The Boyd mine at Sarcoux, twenty-five miles east of Joplin, has resumed, with a force of 80 men, after a shut-down of several months. A heavy flow of water necessitated the use of powerful pumps. Tailing from the Vesuvius mine at Carthage is being treated in a tailing mill formerly operated on the Morning Hour ground at Joplin. This mine was once a bonanza, and much zinc-blende was lost in the waste. The rise in the price of zinc has led to the starting of another tailing mill on the Joplin-Kentucky lease of the St. Louis-Joplin land, where the Zinc Milling & Manufacturing Co. has just completed a new plant. Prospecting abandoned shafts and old workings has also been stimulated by the rise in the metal market. With the advanced ore prices the miners at many mines have demanded their share of increased profits. Machine men, formerly paid \$2.75 per day, asked \$3. Helpers, who received \$2.25, asked \$2.50. Shovelers, who got 5c. per 1000-lb. car, asked for 6c. A compromise was effected to avert a threatened strike. At some of the mills in the Joplin district, which are troubled with barytes in the gangue, experiments are being conducted in roasting. Sufficient heat will cause the grains of heavy spar to explode, after which screening will separate the blende from the barytes.

ALASKA

CHITINA

The railway bridge across the river has been repaired and train service has been resumed.

CIRCLE CITY

Prospects for an active season are excellent. The Berry & Lamb hydraulic plant on Eagle creek, the Clarence Berry giants on Mammoth creek, the Herrington & Leveridge hydraulic plant on upper Mastodon, and the Elmer dredge on Mastodon creek are all preparing for the season's run. A hydraulic plant is also being erected below the mouth of Twelvemile creek and numerous parties of laborers are preparing for hand work.

FAIRBANKS

The output for 1912 is estimated locally at \$5,000,000, with Goldstream at the head with \$800,000. The lode mines are credited with \$250,000, as against \$50,000 for 1911.

IDITAROD

The Guggenheims are reported to have bought placers on Flat creek, and the Bonanza creek dredge at Dawson has been dismantled for shipment to this district.

JUNEAU

The report of the Alaska Treadwell G. M. Co. for April states that 75,292 tons of ore was crushed and 1410 tons of concentrate saved. The estimated value of the free gold was \$97,472.11; of concentrate, \$80,967.53. The value of the total production was \$178,439.64, with a realizable value of \$176,655.25. The estimated net profit was \$69,887. Development work to the extent of 785 ft. was carried on.

KATALLA

The Alaska Development Co. has distributed \$25,000 among stockholders as part proceeds from sale of properties to the Amalgamated company. The Development company is one of the enterprises of C. F. Mundy. It was organized in 1897 and this is the first profit.

NOME

The first passenger steamers are expected about June 11, though smaller mail boats may arrive sooner. About 650 have engaged passage on the *Victoria*, sailing from Seattle June 2.

Five new dredges are being built by the Union Construction Co. for Nome companies.

ARIZONA

COCHISE COUNTY

The Governor has appointed Jack Bolan of Bisbee to be Mining Inspector. Mr. Bolan has been actively engaged in mining for years and was also a member of the constitutional convention.

GILA COUNTY

The Inspiration Con. Copper Co. has begun active construction work. The program outlined by W. H. Aldridge, managing director, calls for an expenditure of \$7,000,000 in the next two years. The concentrator will be built a mile east of the Inspiration mine and a mile north of the town of Miami. The flow-sheet adopted on the recommendation of J. M. Callow, who has been testing the ore for the past year, follows the roughing system developed by the Utah Copper Co. The design of the mill and the purchase of machinery will be left to the company's engineers, Repath and McGregor. The mill will consist of six sections of 1250 tons capacity each, and in addition a steam-power plant for generating a minimum of 7500 hp. will be erected.

The April report of the Miami gives the production of the mill at 2,688,792 lb. of copper from 83,465 tons of ore mined. Over 6600 ft. of underground development work was done during the month, virtually all in ore, and one churn-drill operated in the northeast territory. The company is planning to start diamond-drilling soon to explore the ground below the 570-ft. level. Of the ore

mined during the month, 75% came from development and square-setting next to the capping, 9% from the stock pile, and only 16% from the shrinkage stopes.

Churn-drill hole No. 1 of the South Live Oak Development Co. is 525 ft. deep in granite. At a depth of 435 ft. the drill went through carbonates and silicates of copper, and the samples still show a small amount of these minerals. Commercial ore is reported below a depth of 495 ft. The hole was started with a 17½-in. bit, and a 12-in. bit is now being used.

At the Copper Reef mine, 15 miles south of San Carlos, an Ingersoll-Rand 5-drill compressor and a Stover distillate engine and pump have been installed. Development work will be resumed on the California adit, which is in about 1000 ft. The adit is driven to cut four veins, with good surface showings of copper, at an expected depth of 1200 feet.

The fourth section of the Kingdon shaft of the United Globe mine of the Old Dominion Co. is nearly completed, giving 710 ft. of finished concrete lining. It is believed that the remaining 300 ft. can be finished in one section. The work is being done under contract by C. H. Weideman and Paul Michaelson, construction engineers.

PINAL COUNTY

The report of the Ray Consolidated Copper Co. for the first quarter of 1912 announces an extension of underground workings of 26,487 ft. This development produced 97,000 tons of ore, and 209,000 tons was produced by actual mining operations. Approximately 30% of this output came from territory tributary to the No. 2 shaft. The total amount of ore treated at the mill was 301,674 tons, containing an average of 1.71% copper. The average extraction was 68.85%, making 17,637 tons of concentrate averaging 20.19% copper. The total copper content of the concentrate was 7,122,943 lb. The average cost per pound of net copper after the deduction of smelter allowances was 10.19c. The net profits from operations were \$358,625.92, this earning being based on a price of 15.42c. per pound of copper. This high price resulted from delay in shipments of concentrate to El Paso and in delays in delivery of refined metal to seaboard. The average cost of milling for the quarter, including all charges, was 56.07c. The improvement in results throughout the quarter is indicated in the following table.

	January.	February.	March.
Tonnage treated	99,195	93,794	108,685
Cost per ton of milling.....	63.91c.	56.12c.	48.86c.
Cost per pound net copper..	10.98c.	9.82c.	9.72c.

At the present rate of tonnage only four of the five completed sections of the plant are operated. The work on the sixth section is progressing slowly, so it will be ready for ore about August 1. Since the middle of February all concentrate has been delivered to the A. S. & R. plant at Hayden, and the decrease in cost is largely due to this fact. One furnace of this new smelter was put in operation about May 1, and the plant is being rapidly put into full commission.

CALIFORNIA

AMADOR COUNTY

(Special Correspondence.)—The 20-stamp mill of the East Eureka has been at work since the first of the month on ore taken from development work on the 300-ft. level and is giving good results. It is expected to soon resume work at sinking the north shaft. The Lincoln shaft of the Lincoln Con. has been unwatered to the 1950-ft. level, where development work is in progress. Two shifts are at work driving toward the Wildman shaft to intersect the large ore-body known to exist in the bottom of the Wildman, now a part of the Lincoln holdings. Andrew Noer is superintendent. At the Keystone, under the direction of C. R. Downs, shaft-sinking is in progress, and a depth of 1500 ft. has been reached. It is hoped to find the orebody in the hanging wall which proved productive on the upper levels. At the Bunker Hill 40 stamps are at work and a regular monthly dividend of 7½c. per share is being paid. The Kennedy Extension lying south of the Argonaut, has filed suit

for trespass against the latter company. Near Jackson, south of the Zeila the South Jackson is purchasing machinery and preparing to sink a shaft.

The shaft of the Plymouth Consolidated Co. is unwatered to the 1100-ft. level. The management hopes to have all the water out late in July or early in August, and will then sink 300 ft. deeper. The Alpine, the property just north of the Plymouth, which has been involved financially, has made arrangements for additional funds and expects to resume work in a month or two.

Jackson, May 29.

BUTTE COUNTY

The Nimpshen Ridge Mining & Development Co. incorporated under the laws of Arizona, will resume operations this month. The main adit has been run a distance of 397 ft., and the company plans to run the sluice-boxes into this so that the dirt will be washed as it is mined.

INYO COUNTY

The April production of the Skidoo Mines Co. is given in its report as \$12,508.99 from 1068 tons of ore milled. The cost of operation and development for the month was \$8993.73, giving a net profit of \$3515.26. Only 10 stamps were in operation on account of a shortage of water.

NEVADA COUNTY

(Special Correspondence.)—The North Star Mines Co. has opened a shoot of ore 1 to 3 ft. wide on the 1600-ft. level of the Merrifield mine, one of the Champion properties. The main Champion shaft has been unwatered to a point below the 2300-ft. level. Drifts will be extended from the 2400-ft. level as soon as this point is attained. South drifts are being extended from the Providence shaft toward the Summit claim. At the Spanish Ridge mine the vein recently uncovered by C. Meyer is said to be about 12 ft. wide, with free gold and pyrite scattered through the full width. The surface outcrops of this vein have been traced for 100 ft. Hamilton Bros. have this mine under lease and are operating the 20-stamp mill about 10 days each month.

Grass Valley, May 27.

COLORADO

GILPIN COUNTY

From the Topeka mine is reported the discovery of a 3-ft. vein in the 1100-ft. west level close to the shaft. The ore assays from \$40 to \$300 per ton and is apparently continuous up to the 900-ft. level. Another orebody has been found by diamond-drilling in a parallel vein on the 1200, 1400, and 1500-ft. levels. The present output of this mine is from the 500-ft. level from a vein 2 ft. wide which is nearly exhausted.

TELLER COUNTY (CRIPPLE CREEK)

The owners of the Bolivia mine plan to sink a two-compartment shaft to a depth of 400 ft., in the hope of finding some of the rich flat veins which have been opened up on Tenderfoot hill. The chief stockholders of the Bolivia are bankers of Pueblo. They have allowed the property to remain idle for years, but have now decided to prospect it thoroughly.

The Progressive Mining & Leasing Co., operating the Chicken Hawk mine on Guyot hill, owned by the Katinka Gold Mining Co., has made a first shipment of two carloads of milling ore from the upper levels. Development work is being carried on at the 1000-ft. level.

Electric hoists have been installed on many of the lessees' claims this spring. On the Mountain Beauty a 15-hp. hoist has been placed in order to work the mine to a depth of 250 feet.

A new ore-shoot has been opened up on the 300-ft. level of the Empire State mine in the Emma vein. Four feet of ore is reported in the face of the drift averaging \$24 per ton.

IDAHO

ADA COUNTY

Governor Hawley has called a meeting of mining men at Boise for August 1 to 3. The purpose of the gathering

is to outline needed legislative reforms in mining. Other states will hold conventions later in the fall, and the matter will be taken up by the Northwest Mining Convention in Spokane in February 1913.

COEUR D'ALENE

(Special Correspondence.)—The Bunker Hill & Sullivan M. & C. Co. in 1911 treated 464,750 tons of ore, having a gross value of \$3,306,360. Extraction cost \$1,239,260, with \$1,239,260 additional for reduction and transportation. Repairs and improvements cost \$256,236, forming a total expense account of \$2,507,612, and leaving net profits of \$797,748. Including the April dividend of 1912, this company has disbursed a total of \$13,388,550 in profits to stockholders. The par value of the issued stock is \$3,270,000. With the recently completed new unit, the concentrating plant has a capacity of 35,000 tons per month and is said to be the largest silver-lead plant in the world; 750 electric horse-power is required to operate the plant, and the new unit cost about \$375,000. The works are mounted on concrete foundations, with the native timber superstructure fireproofed throughout. The mill-bins have a capacity of 3000 tons, permitting a two-days run of the plant without drawing upon the mines. Under the new plan of treatment the jig feed is de-slimed in classifying jigs; fine middling reduced by a fine-grinding Hardinge mill, and fine screening conducted through Bunker Hill & Sullivan screens. Esperanza drag-type classifiers and Calumet classifiers are also employed. Gelasio Caetani and Roy S. Hardy were the metallurgists in charge. The company is maintaining a daily production of 1200 to 1400 tons of concentrating ore. Most of this is coming from levels opened below the Kellogg adit, which intersects the vein at a depth of 2000 ft. below the apex. Below this adit three new levels have been driven at intervals of 300 ft., with the latest level being opened 3200 ft. below the surface. Ore conditions in the lowest workings are understood to be particularly satisfactory. A new electric hoist, capable of operating to extensive depth, has been installed. It is operated by a 200-hp. induction motor and will be used exclusively for hoisting ore. The machinery was furnished by the Allis-Chalmers Company.

The Federal company produced a total of 817,100 tons in 1911 from its Mace, Wardner, and Morning mines, with 384,600 tons coming from the last. Total gross earnings aggregated \$5,430,253, of which the Mace properties contributed \$2,029,440. Total costs reached \$4,469,000, leaving net earnings of \$961,253. The Mace mines alone yielded net profits of \$582,675. To date this company has paid dividends of \$6,821,000 on preferred and \$2,708,250 on common stock, a total of \$9,529,250.

The Hecla Mining Co. claimed third position in the Coeur d'Alene as a producer in 1911. The output was 136,479 tons, valued at \$1,001,344. Total costs aggregated \$714,242, leaving net profits of \$287,102. This company has paid a total of \$2,430,000 in dividends. Ore is being mined from the 1200-ft. level and the shaft is going down to the 1600-ft. point. The plant has a capacity of 300 tons per day. The production is 1500 to 1800 tons of crude ore and concentrate per month which is shipped to the smelter of the International S. & R. Co. at Tooele, Utah. About two-thirds of this is concentrate and the rest is crude ore.

Including the Bunker Hill & Sullivan, Federal, and Hecla mines, the nine leading Coeur d'Alene properties produced in 1911 ore to the gross value of \$13,375,178. This represents an increase of over \$1,000,000 above the 1910 figures. The total dividends disbursed amounted to \$2,827,769, a gain of about \$175,000 over 1910 and approximately \$700,000 in excess of the 1909 record. The Snowstorm Mining Co. reported a loss of \$6232, but improvements and repairs represented an expenditure of \$35,547. The company is completing a new concentrating mill at Mullan, the slime from which will be treated in the leaching plant. By this means it is expected to turn the large deposits of low-grade ore to advantage.

IDAHO COUNTY

Work on the Mascot claim has developed an orebody in

the face of the adit 370 ft. from the surface. A 2-stamp mill and a Huntington mill to follow the stamps have been ordered and will arrive as soon as the roads are in shape for the hauling of heavy freight.

SHOSHONE COUNTY

Milling operations have been resumed by the Marsh M. Co. and several shipments of concentrate sent to the International S. & R. Co. at Tooele, Utah, which has a five-year contract for handling the output of the Marsh company. These shipments are said to average \$65 per ton, or about \$50 per ton above freight and treatment charges. It is the plan of the management to continue regular shipments of about 160 tons of concentrate and 350 tons of

MAP OF IDAHO.

crude ore per month, and there is now a large tonnage blocked in the mine. A big electric pump has recently been removed from the No. 2 tunnel to the lower No. 4 level and development work started, with east and west drifts from the cross-cut. The faces of these drifts are now 90 ft. apart and ore is exposed for the full length.

ILLINOIS

The new plant of the American Z. L. & S. Co. at Hillsboro, is reported as nearly completed and is expected to start early in August. The officials claim that this will be the 'show plant' of the country for appearance, workmanship, and material, and also for economical operation.

MONTANA

SILVERBOW COUNTY

(Special Correspondence.)—The Davis-Daly C. Co. reports a body of ore with about 3% copper and over 4 oz. silver per ton in the 1900-ft. level of the Colorado mine. Cross-cutting is proceeding both north and west, and the management expects to block a good body of shipping copper ore. The Butte-Ballaklava is averaging about three carloads per week to the East Butte smelter. Development and mining on the 1400 and 1600-ft. levels are producing this ore. It is expected that the suit with the Anaconda company involving the question of ownership of ore will be brought up in the federal court this month. The East Butte company smelter will not be in a position to increase production before August 1. Two months ago the company commenced the work of increasing the furnace ca-

pace by lengthening two furnaces. Sixty days more will be required to complete the first furnace, and four months will elapse before the second furnace is finished. When the work is completed the smelter capacity will be about 2,000,000 lb. of copper per month, instead of the present rate of 1,250,000 lb. The cross-cutting north and south from the shaft on the 2800-ft. level of the North Butte mine is proceeding at the rate of 5 ft. per day, but the company does not expect to reach the Edith May and Jessie veins for a few weeks. Development is going on at the 2000, 2200, and 2600-ft. levels, and the production is continuing at about 2,000,000 lb. of copper per month. It has been stated in Eastern papers that the ore reserves have been greatly diminished, but this is absolutely denied, and it is announced that the mine is in as good condition as at the time of the last annual report. Experiments in electric drills have not yet been successful, but will be continued. The foundation for the concentrator of the Butte Central Copper Co. will be completed in about two weeks, and the building material and machinery are expected on the ground by that time. The superintendent says he will have the mill in operation by October 1, with an initial capacity of 200 tons per day. Plans are made for a possible enlargement to 500 tons per day later. Shipments of ore to the Washoe smelter have been stopped by order of the directors, and all ore will be held for the new mill. Development on the 200, 300, and 500-ft. levels is blocking out a large body of second-grade ore. The first unit of the Butte & Superior company smelter is now treating about 400 tons per day and the management is attempting to increase capacity to 500. Delivery on the new surface plant of the company is expected in a few weeks and work will be immediately commenced on erection. There will be no curtailment of operations during this construction, as enough ore is stored at the surface to keep the concentrator in operation.

Butte, May 27.

NEVADA

ESMERALDA COUNTY

(Telegraphic Correspondence.)—The April report of the Goldfield Consolidated Mining Co. shows the total output of the mines for the month as 28,360 tons, containing \$610,708.20, or \$21.53 per ton. The mill treated 27,928 tons, with an extraction of 93.77%, and 432 tons of ore averaging \$28.60 was shipped. The net recovery on all the ore treated averaged \$20.20 per ton. The operating costs, including a construction charge of 25c., were \$6.53 per ton. The total net realization was \$392,056.17. Development for the month totaled 3396 ft. An encouraging discovery is reported in the 1300-ft. level of the Grizzly Bear workings, where a cross-cut passed through shale into quartz with low-grade ore, containing gold, silver, and copper. The seam is from 1 to 3 ft. wide and samples have assayed from \$15 to \$50 per ton. No driving has been attempted, as the face of the cross-cut is still in ore. This is apparently the downward extension of the base orebody exposed in the 1000-ft. level of the Clermont. The showings in the Mohawk, Combination, and Laguna are highly satisfactory.

Goldfield, May 29.

The management of the Pittsburg Silver Peak announces a wage cut, effective June 1. The wage scale of this company has been the highest in the state of Nevada, machinists, electricians, and skilled laborers receiving 50c. per day more than in Tonopah, while shovelers' wages have been higher than in Goldfield. The property is operated through adits, and conditions for working are healthful.

The new plant of the Goldfield Merger Mines Co. was put in operation last week, after a champagne christening and speeches from the company officials. The new head-frame covers a shaft 7 by 18 ft. in the clear, which had been driven to a depth of 1000 ft. with the original equipment. Sinking will now be resumed from this level.

NYE COUNTY

The Tonopah Belmont Development Co. reports net profits of \$143,005 for the month of April from the milling of 8390 tons. Good progress has been made on the

construction of the new mill which is planned to treat 15,000 tons per month. On the concentrating-floor all tables are now in place with motors and driving pulleys, and on the floor above the light tube-mills are also ready to start. On the tank floors pipe connections are being made. The roofing and sides of the building are completed, and the electrical wiring is being rushed. The new triple-compartment shaft is now sunk to a depth of 145 ft. Underground development on the 1100 and 1200-ft. levels has been continued and additional low-grade ore opened in the drifts.

For the West End mill, 12 new Deister concentrating-tables have been ordered. The operation of these tables will increase the output of the mill by 20 tons daily. Shipments of the richer ore to the smelters will continue at irregular intervals. The company will this week take over the Santa Rosa lead mine, 26 miles from Keller in Inyo county, California, and S. H. Brady will act as consulting engineer in the further development of the mine. The property is now producing ore netting \$40 per ton and the present output of the mine will be greatly increased. The MacNamara mill is reported as treating 65 tons of ore daily with excellent recovery. The development on the mine has opened an orebody on the 300 and 375-ft. level averaging \$25 per ton.

The Tonopah M. Co. reports 3348 tons of ore crushed at the mill in April with 98 out of the 100 stamps constantly dropping. The average value of the ore was \$17 per ton, and the extraction for the month was 90%. The total tonnage treated was less than in March by 864 tons, but with the increased price of silver and higher grade ore the total profits have been above dividend requirements.

The annual meeting of the stockholders of the Tonopah Extension company was held in New York on May 10. The financial statement presented shows gross earnings for the year of \$590,418, with a mining cost of \$240,551 and a milling cost of \$165,278. Refining and express charges bring the total cost up to \$417,000 for operating expense. The average mineral content of the ore was 16 oz. silver and 0.17 oz. gold per ton. The mill is now treating an average of 147 tons daily, and development has demonstrated strong orebodies. The Montana-Tonopah reports 1000 tons of ore treated per week with 89.1% extraction. The shaft of the Halifax-Tonopah M. Co. has now reached a depth of 1200 ft. Several small stringers of ore have been cut. At the Gipsy Queen an electric hoist and compressor plant has been installed and work on repairs to the shaft timbers has commenced. It is intended to start driving on the vein at the 500-ft. level and thoroughly prospect this vein for an orebody. The surface equipment for the 76 Consolidated M. Co. is being installed and sinking has been suspended until the new hoisting machinery and head-frame are in place.

The Manhattan Eagle M. Co. has been organized by C. E. Mayne to take over the Manhattan Blue Jay property. A 200-ft. shaft is planned.

STOREY COUNTY

The Ophir company has filed a statement with the tax collector which shows for the first quarter of 1912 a gross tonnage of 3396, the bullion yield of which was \$96,893. The extraction costs were \$68,365; transportation \$1643; reduction and selling \$13,836. The net yield was \$13,048. The Comstock-Phoenix mine, operating on the Brunswick lode south of Sixmile canyon, shipped to Fisher mill during the first quarter of the year 350 tons. The gross bullion yield on this ore was \$27,048, with the cost of extraction, transportation, and reduction \$15,804. Consolidated Virginia for the first quarter of the year extracted 255 tons from the mine, but there were no milling returns, as the reduction of the accumulated ores did not start until May. The Yellow Jacket company for the first three months of the year milled 2138 tons of ore from the dump, the gross yield from which was \$10,497, with transportation charges of \$970.

The Beleher company did no milling for the quarter, but extracted 223 tons of low-grade ore. Crown Point milled 4586 tons of ore at the Yellow Jacket mill, the gross yield being \$23,765, with costs of \$23,576. The Cholla Leasing

Co., operating at the croppings of Chollar and Potosi shipped 2615 tons to the Butlers plant under lease, yielding \$15,378. The cost of extraction was \$10,790, transportation \$784, and reduction \$6613.

NEW MEXICO

GRANT COUNTY

The Chino Copper Co. reports for the quarter ended March 31 an output from the steam-shovel pits of 229,000 tons of ore at a cost of 14.47c. per ton. The total material removed includes 619,000 cu. yd. of stripping at a cost of 27.28c. per yard. Beginning with the second quarter of 1912, a charge of 30c. per ton will be made against all ore mined, to cover the shipping cost. The concentrator treated 160,400 tons in two sections. The third section of the mill was finished and ready for operation at the end of March. The production of the concentrator was 8048 tons of concentrate containing an average of 20.33 lb. of copper per ton. This low content was due to the fact that the ore mined was from the upper part of the orebody, where the copper occurs in carbonates. The average cost per pound of net copper after deducting smelter allowance was 7.48c. The net income for the quarter amounted to \$228,021, figured on an average price of 13.85c. per pound for copper.

SOCORRO COUNTY

(Special Correspondence.)—The unwatering of the Deadwood mines is about completed, after which development work will be pushed in the lower levels. The upper levels are producing a fair tonnage from development drifts, and in the third level a good orebody has been found. The daily ore treatment is 60 tons, part of which comes from custom ore. The Pacific mine of the Oaks Co. shipped 34 tons from 20 ft. of development, and the Johnson mine shipped 21 tons mined in sinking the shaft 18 ft. This ore was treated at the Deadwood mill, and the Deep Down mine is also shipping ore to the mill from the development conducted by lessees. The Socorro mines milled 1250 tons during the week, drawn largely from the lower levels. The Treasure Mining & Reduction Co. milled 480 tons for the week. The company claims to have enough ore broken in the stopes to supply the mill for six months and to have a good showing in the lower levels from development work.

Mogollon, May 24.

OREGON

BAKER COUNTY

The Ben Harrison mine, 28 miles west of Sumpter, has been opened to a depth of 500 ft., and one ore-shoot has a width of 9 ft. and a length of 250 ft., while another is 100 ft. long and 6 ft. wide. Plans are being made for the erection of a 200-ton all-sliming cyanide plant. Work on the new dredge near Sumpter is progressing rapidly. The derriek and other machinery used in construction is operated by electric power.

LANE COUNTY

The Oregon Highgrade G. M. Co. has been organized to operate on claims located 45 miles southeast of Eugene last fall by Leslie Furlong. While placing Mr. Furlong found float which he followed to a vein outcropping in the hillside. From this he took 105 lb. of specimen rock that sold for over \$600. He put down several pits, located five claims, and drove an adit 17 ft. It is claimed that 36 in. of quartz assays \$188. The new company is composed of San Francisco men, including R. F. Petry, W. A. Scott, and M. J. Seeley.

UTAH

SALT LAKE COUNTY

The April production of the Utah Copper Co. was reported as 9,069,237 lb. copper, and the output of Nevada Consolidated as 6,115,059. The tenth section in the Arthur mill is now treating ore, and the eleventh section is ready for operation. At a recent meeting of the directors of the Michigan-Utah Consolidated Co., Duncan MacVichie resigned as president, and Norman C. Haire was elected to the position.

WASHINGTON**KING COUNTY**

(Special Correspondence.)—The United States S. R. & M. Co. has established a branch office of its exploration department at 1303 Hoge building, Seattle, Washington, with D. D. Muir, Jr., engineer in charge. Apparently the United States company is preparing to get a holding in Alaska, as it announces it is prepared to examine for purchase any meritorious metal properties in the Northwest and Alaska. Seattle, May 24.

STEVENS COUNTY

The United Copper mine at Chewalah is producing 110 tons of ore per day, of which 75 tons is milled and 35 tons shipped. A mill, to cost \$35,000, is to be built at the Gwinne mine, Gifford, near Colville.

CANADA**BRITISH COLUMBIA**

The Consolidated Mining & Smelting Co. has planned to expend \$100,000 in improving its smelter at Trail. Furnaces will be built for treating the raw matte direct, eliminating the preliminary roasting. An addition will also be made to the lead refinery to accommodate 84 additional tanks, giving the plant a total of 324 tanks and increasing the capacity 100 tons per day.

A new stamp-mill with a daily capacity of 70 tons is in operation on the Mother Lode mine on Sheep creek. The company claims to have 50,000 tons of free-milling ore averaging \$25 per ton blocked out.

The report of the Hedley G. M. Co. for the first quarter of 1912 shows that 16,958 tons has been crushed, yielding a profit of \$76,676. The gold content of the ore varies from month to month, but is not far from \$10.50 per ton. The average profit per ton during 1911 was \$5.34.

ONTARIO

The Dome mine has made a recent shipment of bullion valued at \$20,000. This brings the total output of six weeks' operation of the mill up to \$61,500. This does not represent full capacity, as the entire stamp battery was not in operation nor the mill in perfect running order. The mill is now speeding up and bullion shipments will be made twice a week. Work on the Hollinger mill is being rushed and the concentrating machinery has been placed. The wiring and piping still remains to be done, but the management hopes to start operations soon after June 1. The building of the refinery will be pushed, in order to be ready for the first amalgam from the plates.

YUKON

The first dredge of the Yukon Gold Co. began work on May 3. Seven out of nine boats are now at work. There is plenty of water and everything is running smoothly.

MEXICO**SONORA**

It is expected that the May output of the Greene-Canea will be between five and six million pounds of copper. The converting capacity will be immediately enlarged to handle the increased output of matte.

JALISCO

The El Favor mine, in the Hostotipaquillo district, sent out 10 carloads of ore during the first ten days of May. Shipments of high-grade ore from the Mololoa mine have been delayed by making air connections. The new machinery recently received at the El Favor plant is in course of erection.

HONDURAS

The Chanton mine, in the department of Comayagua, is regarded as of much promise. It is under the direction of United States people and American machinery has recently been forwarded to the mine, together with engineers to install it. Petroleum was found on Gnare mountain, department of Comayagua, some years ago, by Calixto Marin, and recent exploration indicates that the oil is of excellent quality and the supply abundant.

Personal

Professional men are invited to send news of their engagements and travels. Such news is interesting to friends.

J. F. NEWSOM has gone to Alaska.

O. B. PERRY was at Palo Alto this week.

ALFRED WILLIAMS is visiting California.

W. M. WITHER has gone to Council, Alaska.

R. G. SMITH leaves today for Nome, Alaska.

F. L. WILSON has gone to Ingot, California.

C. T. NICHOLSON is leaving for the Yukon and Alaska.

A. J. HEISTER has gone to Chicago from Golden, Colorado.

EARL M. BAGLEY has returned to Alameda from Jackson.

W. W. MEIN is removing from San Francisco to New York.

MAX J. WELCH will be in Los Angeles during June and July.

EDWARD J. MAY has moved from Cobalt to Colorado Springs.

J. MORGAN CLEMENTS has gone to northern British Columbia.

T. T. READ has been visiting the Mother Lode mines of California.

J. W. ABBOTT has gone to Los Angeles on his way to Pioche, Nevada.

STEWART BLACKBURN is taking a trip through Arizona and New Mexico.

R. M. JONES has spent the past week at Manhattan and Round Mountain.

W. P. HAMMON was in New York last week, but has returned to London.

HOWLAND BANCROFT has removed his office to 730 Symes building, Denver, Colorado.

G. H. RUSSELL passed through San Francisco this week on his way to Council, Alaska.

JOSEPH H. PLAYTER was in San Francisco recently and has returned to Golconda, Nevada.

Z. CUSHING was in San Francisco this week on his way to Juneau and other Alaskan points.

ROY H. ALLEN, who has been at Villa Escobedo, Chihuahua, Mexico, is now at Lunenburg, Massachusetts.

R. B. LAMB is leaving Toronto for an extended professional trip to Swastika, Porcupine, and Gowganda.

ROBERT B. MORAN has removed his office from 519 California street to 220 Insurance building, San Francisco.

CHARLES A. CHASE has removed his office from 921 Equitable building to 734 First National Bank building, Denver.

JAMES HODGSON, of Ishpeming, Michigan, has succeeded PARKER L. WOODMAN as superintendent of the Copper Queen mine.

F. C. NEWTON has gone East to become superintendent at the Perth Amboy plant of the American Smelting & Refining Company.

R. W. PRINGLE has opened offices in Union buildings, Gatooma, South Rhodesia, for mining engineering and metallurgical work.

J. R. FINLAY delivered an address at the commencement exercises at the School of Mines, University of Missouri, at Rolla, on May 30.

The firm Worthington & Pickard has been dissolved, and B. O. PICKARD will serve his clients from an independent office at Phoenix, Arizona.

GEORGE J. HOUGH, formerly in the custom assay business at Salida, Colorado, recently received a government appointment in the Bureau of Chemistry at Washington, D. C.

J. G. KIRCHEN had a narrow escape from drowning while fishing with C. M. SCHWAB at Martins Creek, Pennsylvania. It is related that after he was rescued the two fishermen returned undisturbed to the task in hand.

LOCAL METAL PRICES

San Francisco May 29.

San Francisco is not a primary market for the common metals except quicksilver. The prices quoted below therefore represent sales of small lots and are not such as an ore-producer could expect to realize. Ore contracts usually call for settlements on the basis of Eastern prices, less freight and treatment charges. The prices quoted are in cents per pound, except in the case of quicksilver, which is quoted in dollars per flask of 75 pounds.

Antimony.....11-11 1/2c	Quicksilver (flask).....42
Electrolytic Copper.....17-17 1/2c	Tin.....50-51 1/2c
Pig Lead.....4.15-5.40c	Spelter.....7 1/2-7 3/4c
Zinc dust, 1400 lb. casks, per 100 lb., small lots \$9.50-9.75; large \$7.50-8.50	

METAL PRICES

(By wire from New York.)

NEW YORK, May 29.—During the past week copper has been strong and advancing. The demand continues good, both in this country and abroad. Lead and spelter prices are quiet but firm.

Average daily prices for the past week, in cents per pound, based on wholesale transactions, standard brands, are given below.

Date.	Electrolytic Copper.	Lead.	Spelter.	Silver, per oz.
May 23.....	16.35	4.20	6.73	61
" 24.....	16.35	4.20	6.73	60 1/2
" 25.....	16.35	4.20	6.73	61 1/2
" 26.....	Sunday.	No market.		
" 27.....	16.40	4.20	6.73	61
" 28.....	16.48	4.20	6.73	61

SILVER

Below is given the average New York quotation, in cents per ounce, of fine silver for the months indicated:

	1911.	1912.		1911.	1912.
Jan.	53.81	56.25	July	52.57
Feb.	52.23	59.06	Aug.	52.17
Mch.	52.76	58.37	Sept.	52.43
Apr.	52.32	59.20	Oct.	53.37
May	53.31	61.00	Nov.	55.77
June	53.04	Dec.	54.85

COPPER

Daily quotations on copper as published in this column represent average wholesale transactions on the New York market and refer to electrolytic copper. Lake copper commands normally from 1-5 to 1-4c. per lb. more. Below are average monthly quotations in cents per pound:

	1911.	1912.		1911.	1912.
Jan.	12.29	14.09	July	12.47
Feb.	12.26	14.08	Aug.	12.41
Mch.	12.14	14.68	Sept.	12.20
Apr.	12.02	15.74	Oct.	12.19
May	11.99	16.05	Nov.	12.61
June	12.39	Dec.	13.55

COPPER SURPLUS

Figures showing the visible supply of copper at the beginning of each month are now widely available. Below are given the amounts, in pounds, known to be available at the first of each of certain months.

	U. S.	European.
January 1910.....	141,766,111	244,961,280
January 1911.....	122,030,195	230,264,280
September ".....	133,441,501	191,215,360
October ".....	140,894,856	191,945,600
November ".....	134,997,642	176,816,640
December ".....	111,785,188	164,151,680

January 1912.....	119,337,753	62,343,901	80,167,904
February.....	116,035,809	56,228,368	63,148,096
March.....	125,694,601	67,847,556	58,779,566
April.....	125,694,001	69,513,846	53,252,326

LEAD

Lead is quoted ordinarily in cents per pound or dollars per hundred pounds delivered at St. Louis or New York. The difference is normally 15c. per hundred pounds, and any larger or smaller difference is promptly met by sales. The daily price in New York is published each week in this column. Below are the average quotations by months:

	1911.	1912.		1911.	1912.
Jan.	4.48	4.43	July	4.50
Feb.	4.44	4.03	Aug.	4.50
Mch.	4.39	4.07	Sept.	4.48
Apr.	4.41	4.20	Oct.	4.27
May	4.37	4.20	Nov.	4.30
June	4.34	Dec.	4.45

ZINC

Zinc is quoted as spelter, standard Western brands, and based upon St. Louis or New York delivery. While New York quotations, as a matter of convenience, are commonly used, relatively little spelter actually goes to or comes from New York. The bulk is shipped direct from the plants in the Mississippi Valley to manufacturers, due allowance being made for freight. New York daily quotations are published in this column each week. Below are given averages by months:

	1911.	1912.		1911.	1912.
Jan.	5.45	6.42	July	5.70
Feb.	5.52	6.50	Aug.	5.95
Mch.	5.56	6.57	Sept.	5.86
Apr.	5.40	6.63	Oct.	6.10
May	5.35	6.70	Nov.	6.38
June	5.50	Dec.	6.30

Zinc-dust is quoted separately, the price being based upon the cost of spelter in Illinois and the cost of preparation. About half the zinc-dust used in the United States is imported through San Francisco. Delivery prices are determined largely by quantities and contracts.

QUICKSILVER

The primary market for quicksilver is San Francisco, California, being the largest producer. The price is fixed in the open market, and, as quoted weekly in this column, is that at which moderate quantities are sold. Buyers by the carload can usually obtain a slight reduction, and those wanting but a flask or two must expect to pay a slightly higher price. Average monthly quotations, in dollars, per flask of 75 lb., are given below:

	1911.	1912.		1911.	1912.
Jan.	44.60	43.75	July	48.00
Feb.	48.40	46.00	Aug.	50.00
Mch.	52.50	46.00	Sept.	47.50
Apr.	50.90	42.25	Oct.	46.12
May	46.50	41.75	Nov.	45.50
June	46.50	Dec.	44.50

TIN

New York prices control in the American market for tin, since the metal is almost entirely imported. San Francisco quotations, averaging about 5c. per lb. higher than New York, are quoted weekly in this column. Below are given average monthly New York quotations in cents per pound:

	1911.	1912.		1911.	1912.
Jan.	41.25	42.53	July	42.40
Feb.	41.61	42.96	Aug.	43.32
Mch.	40.16	42.58	Sept.	39.75
Apr.	42.18	43.92	Oct.	41.18
May	43.11	46.12	Nov.	43.12
June	44.61	Dec.	44.65

Current Prices For Chemicals

(Corrected monthly by Braun-Knecht-Heimann Co.)

Prices quoted are for ordinary quantities in packages as specified. For round lots lower prices may be expected, while in smaller quantities advanced prices are ordinarily charged. Prices named are subject to fluctuation. Other conditions govern Mexican and foreign business.

Tin ore, 60%, $\frac{1}{2}$ ton	450.00	475.00
Tungsten ore, 65%, $\frac{1}{2}$ ton	300.00	455.00
Vanadium ore, 15%, $\frac{1}{2}$ ton	150.00	180.00
Wolframite (see tungsten ore).		
Zinc ore, 50 % up, $\frac{1}{2}$ ton	*15.00	20.00

California Gem Stones

As is well known, a variety of gem stones are found in California and a number of local firms are engaged in cutting and selling them. The price per carat varies according to color and quality. Below are quoted representative sale prices. Crude material sells for much less, and there are no regular quotations. The prices here given serve to indicate the relative value of the gems:

Tourmaline.—Stones from ½ carat up to 4 carats, at from \$4 to \$8 per carat, diamond cut; this price for the pink, red, green, yellow, blue, and water color; stones cut cabachon (with a smooth curved surface), \$2 to \$8 per carat.

Kunzite.—San Diego and Riverside county stones in shades of a delicate rose pink, brilliant amethystine purple, deep lavender, rich golden yellow, and water color; diamond cut, ¼ carat up to 10 carats; \$5 to \$10 per carat.

Hyacinth.—Cut cabachon, from 1 to 10 carats in size, 75c. to \$3 per carat.

Californite (Vesuvianite or California jade).—Cabachon cut, stones 1 to 20 carats in size, \$1 to \$2 per carat.

Washingtonite.—Cabachon cut, stones 1 to 4 carats in size, \$3 to \$5 per carat.

Beryl.—Diamond-cut beryls, red, pink, yellow, aquamarine, citron yellow, and wine color, from ¼ carat to 3 carats, \$3 to \$5 per carat; emerald beryls, ¼ to 3 carats, \$10 to \$30 per carat; cabachon-cut beryls, red, pink, yellow, aquamarine, citron yellow, and wine color, \$2 to \$4 per carat; emerald beryl, cabachon cut, 1 to 3 carats, \$8 to \$20 per carat.

Peridot.—Diamond cut, 1 to 3 carats, \$3 to \$5 per carat.

Topaz.—White, \$1.50 to \$3 per carat; royal, \$3 to \$5 per carat; yellow, \$2 to \$4 per carat; sea-green, \$3 to \$5 per carat; wine color, and smoky topaz, \$1.50 to \$3 per carat.

Turquoise.—Clear and matrix turquoise in both oval and round shapes, from 1 to 10 carats in size, 50c. to \$1 per carat.

California Ruby (Garnet).—Diamond cut, 1 to 4 carats, \$1.50 to \$3 per carat.

Eldorado Gem.—This is the latest gem on the market and when mounted one of the most beautiful; it is found in Eldorado county, and is a delicate canary yellow color; 1 to 2 carats, \$10 per carat.

Green Chalcedony (Chrysoprase).—Stones cut rounding or cabachon, 1 to 20 carats, 75c. to \$2 per carat.

Jasper.—Stones from 1 to 20 carats, cabachon cut, 50c. to 75c. per carat.

Benitoite.—Rare; 1 to 2 carats, diamond cut, \$10 to \$20 per carat.

Amethyst.—Diamond cut, 1 to 5 carats, 75c. to \$1.75 per carat; cabachon cut, 1 to 10 carats, 50c. to \$1 per carat.

Rock Crystal.—Cubes one inch square, \$1 each.

Azurite-Malachite.—2 to 10 carats, 50c. to \$3 per carat.

Rose Quartz.—Cabachon cut, 2 to 20 carats, 50c. per carat.

California Moonstone.—Cabachon cut, 1 to 10 carats, 25c. per carat.

Jasperine.—Cubes one inch square, \$1 each.

Moss Agate (Chalcedony).—Cabachon cut, 2 to 4 carats, 75c. per carat.

Utahlite.—Cabachon cut, 1 to 3 carats, \$2 per carat.

Chrysocolla.—Cabachon cut, stones from 1 to 5 carats, 75c. per carat.

Bloodstone.—Cabachon cut, 1 to 10 carats, 75c. per carat.

Amazon Stone.—Cabachon cut, 1 to 5 carats, 75c. per carat.

Rutile Crystal.—Transparent quartz crystals, penetrated with long slender crystals of brilliant red rutile (oxide of titanium); cut in small cubes and polished for paper-weights, \$1.50 each; crystals uncut, \$1.

Chlorite Phantom Crystals.—Quartz crystals, with pecu-

liar inclusions of chlorite; cubes one inch square at \$2 each; uncut crystals, \$1 to \$5 each.

Axinite.—Diamond cut, \$5 per carat.

Labradorite.—White, yellow, red; cabachon cut, 1 to 5 carats, \$1 per carat.

James Lewis & Son's Copper Report

Standard copper during April varied in value to the extent of £2 per ton, opening at £70 17s. 6d. for cash, rising to £71 5s. 0d. on April 2, and falling to £69 5s. 0d. on April 10. After improving to £70 13s. 9d. on April 16 it declined to £69 8s. 9d. on April 23, recovered to £70 11s. 3d. on April 24, but reacted the same day to £70. Up to £70 13s. 9d. was paid on April 29, and the closing value May 1 was £70 3s. 9d. cash and £71 three months prompt. Sales for the month represent about 52,000 tons. Refined copper has been in good demand since the termination of the coal strike, English consumers chiefly supplying their wants from the stock of American copper held in England, the quantity of which is steadily diminishing. American producers, being well sold for delivery over the next two months, hold for 16c. per pound, or the equivalent of £74 per ton c.i.f.

German consumption for the first three months of this year shows an increase of 15,219 tons—54,325 tons as compared with 39,106 tons in the same period last year. This makes the total European consumption 106,106 tons this year as against 84,434 tons last year, an increase of 21,672 tons, the increase in American consumption being 12,224 tons, or a total increase of 33,896 tons for the three months. Against this there is an increase of 2237 tons in American production and imports and a decrease in the imports into Europe from other countries of 5030 tons, or a total decrease of 2793 tons. American shipments from Northern ports for April are given as 22,341 tons. European stocks have decreased 2208 tons, and the visible supply 1183 tons during the month. Imports are 2106 tons less and deliveries 733 tons greater than during the same period last year.

The total arrivals in England and France for April were 14,956 tons, and the deliveries 16,385 tons fine. The arrivals in England from Chile during April were 1449 and the deliveries 1053 tons fine, and from other countries 7136 and 8578 tons fine respectively. The arrivals at Liverpool and in Swansea from the United States have been 2225 tons bars, etc., and 102 tons plates, etc., equal to about 2302 tons fine copper, in London 726 and in France 4145 tons fine. The Chile charters for the month are advised as 2900 tons, including 1725 tons for the United States. Quotations May 1 were: Standard, £70 3s. 9d. for cash and £71 0s. 0d. three months' prompt; English best selected ingots, £74 5s. 0d. to £75 5s. 0d., and tough cake, £74 5s. 0d. to £75 5s. 0d. per ton, less 2½% delivered Birmingham. Electrolytic wire bars, £74 0s. to £74 10s. net cash c.i.f.: 12s. 3d. to 12s. 6d. for ore of 20%, and 12s. 9d. to 13s. 0d. per unit for Chile regulus or American matte free from silver.

PETROLEUM AND NATURAL GAS IN UTAH. By E. G. Woodruff. Part II.—Mineral Fuels. Advance Chapter from Contributions to Economic Geology (Short Papers and Preliminary Reports), 1910. Bull. 471—A-4. 29 pp.; maps. U. S. Geol. Surv. Washington, 1912.

PRODUCTION OF MICA IN 1911. By Douglas B. Sterrett. U. S. Geol. Surv., Adv. Chapter Mineral Resources. 9 pp. Washington, 1912. This paper covers the occurrence, nature, and uses of mica, as well as figures of production. The total value of the mica output in the United States in 1911 was \$355,804, being \$18,707 greater than in 1910. The sheet mica production amounted to 1,887,201 lb., and scrap mica to 3512 short tons.

GEYSERS. By Walter Harvey Weed. Pub. on Yellowstone Park. 29 pp. Dept. Interior, Washington, 1912. Price 10 cents. This pamphlet, which may be purchased from the Superintendent of Documents, Government Printing Office, Washington, D. C., includes a map of Yellowstone Park showing the situation of the various geysers, and numerous illustrations of them. The text covers the nature of geysers and a description of the more important geyser regions of the world. The paper will be of especial interest to intending visitors.

NEW ZEALAND. ROYAL COMMISSION ON MINES. 453 pp. Wellington, 1912. This volume covers reports on the Prevention of Accidents; Ventilation of Mines; Underground Sanitation of Mines; Change and Bath Houses for Miners; Profitable Utilization of the Soft Bituminous and Lignite Coals of the Westport District; and Minutes of Evidence and Exhibits. The report is based upon studies of a commission consisting of N. D. Cochrane, John Dowgray, J. S. Evans, George Fletcher, H. S. Molineaux, W. E. Parry, and Frank Reed. It is replete with data of interest to both metalliferous and coal miners.

PRODUCTION OF GRAPHITE IN 1911. By Edson S. Bastin. U. S. Geol. Surv., Adv. Chapter 'Mineral Resources.' 38 pp. Washington, 1912. This report covers the origin, properties, and uses of graphite; the production, considered by states and countries; markets and prices; foreign deposits; and a bibliography of the subject. It is, in fact, a handbook in miniature, and an excellent one. In 1911 the United States imported 20,702 short tons of graphite valued at \$1,495,729, and produced 3618 short tons of natural graphite valued at \$288,465, with 5072 short tons of manufactured graphite worth \$664,000.

Book Reviews

Any of the books noticed in these columns are for sale by, or can be procured from, the MINING AND SCIENTIFIC PRESS.

LABORATORY MANUAL FOR TESTING MATERIALS OF CONSTRUCTION. By L. A. Waterbury. John Wiley & Sons. Pp. 270, index. For sale by the *Mining and Scientific Press*. Price \$1.50.

As the title implies, this book is written for the use of students as a text-book in laboratory testing practice. The subject matter covers testing of all known building materials, and is treated under the heading of general instructions, laboratory work, preparation of reports, description of apparatus, tests of cement, tests of concrete, concrete, iron, steel, wood, brick, sand, gravel, stone, and asphalt. Appendices supplement the matter in the body of the text and give the reports of the sub-committees of the various engineering societies bearing upon the subject, and include progress report on uniform tests of cement, standard specifications for cement, method suggested for the analysis of limestones, raw mixtures, and portland cements, progress report of special committee on concrete and reinforced concrete, standard specifications for structural steel for bridges and buildings, standard specifications for open-hearth boiler plate and rivet steel, and requirements for paving brick. The entire book is comprehensive in its treatment of the various subjects and replete with information. An excellent index facilitates ready reference to any detail contained in the subject matter.

OBSERVATIONS ON THE WEST OF ENGLAND MINING REGION. By J. H. Collins. Pp. 683. Ill., index. Printed for the author by Wm. Brendon & Son, Ltd., Plymouth, England. 1912. For sale by the *Mining and Scientific Press*. Price \$7.

This volume, which is No. XIV of the Transactions of the Royal Geological Society of Cornwall, is essentially a discussion of the mineral deposits of Cornwall and Devon. It opens with an introductory chapter on ore deposits in general, which is followed by several describing the particular forms of deposits that are found in Cornwall. These in turn are followed by detailed descriptions of the individual mines. The descriptive chapters are supplemented by several discussion underground water, lode fillings, metamorphism, ores and vein stones, the age of the veins, and similar general topics. There are several appendices, including one that is made up of an alphabetical list of the mines. The book is really a discussion of ore genesis with illustrations taken from Cornwall, and it has been written by one who knows both the area and the literature of his subject.

Cornwall was well known to the earlier mining engineers, but there are many now active in the profession who not only have never visited the country but have no clear conception of it and its classic deposits. To them, particularly, Mr. Collins has rendered a valuable service, since he has brought together in one convenient and accessible volume a great mass of previously scattered data. The tin lodes of Cornwall will probably always stand as one great type of deposit, and with a view to general discussion of ore genesis Mr. Collins' book is especially welcome. Cornwall is peculiar not only in its deposits and methods but in its language, and to read about the country one needs always a special dictionary lest he stumble over killas, petuntzite, elvans, or other things for which the world in general has other names. If Mr. Collins has not altogether escaped from the maze of local, and to foreigners barbarous, names for simple things he has at least made an earnest attempt and removed some of the obstructions from the road. The book is too large and too detailed to review adequately here, and none but a Cornishman would dare to question an authority such as Mr. Collins. It is evidently based upon close observation, long thought, and wide reading, and it is sure to be extremely helpful to those of us who must depend upon others for a knowledge of the Duchy to which all mining men owe so much.

Decisions Relating to Mining

Specially reported for the MINING AND SCIENTIFIC PRESS.

INVALID LOCATION—NO INUREMENT TO LOCATOR

An attempted location of a mining claim, based upon a discovery within a then valid and subsisting claim, is absolutely void for the purpose of founding an adverse claim, and does not attach upon the subsequent failure of the first locator to do the required annual assessment work.

Swanson v. Sears, (U. S. Supreme Court) 32 Supreme Court Reporter, 455. April 1, 1912.

LOCATION OF FORFEITED CLAIMS IN ARIZONA

In Arizona a state statute requires that a notice of location of mining property which has been forfeited for failure to do the necessary assessment work, must state that the claim located has been forfeited or abandoned. On appeal to the United States Supreme Court it was held that this statute does not conflict with the federal mining laws.

Clason v. Matko, 32 Supreme Court Reporter, 392. March 11, 1912.

TAKING ORE—LESSORS JOINTLY LIABLE

Where the lessees of one party entered upon another party's land and extracted gold therefrom, and paid a part of the gold so extracted to their lessors as royalties from the lessors' land, the lessors being cognizant of and acquiescing in the taking of the ore, were jointly liable with their lessees to the injured party, to the extent of the royalties which they received.

G. & P. C. Merriam Co. v. Saalfeld, (Alaska) 190 Federal, 927. October 28, 1911.

OIL AND GAS LEASE—IMPLIED COVENANT FOR DILIGENCE

Where an oil and gas lease gives the lessee the right to explore and develop the property and operate wells thereon without limitation as to time, but provides for substantial royalties to be paid the lessor, there is an implied covenant on the part of the lessee to develop the property and operate the wells drilled thereon with reasonable diligence and in good faith. A failure to commence development for nearly six years was in this case held to entitle the lessor to cancel the lease.

People's Gas Co. v. Dean, (Kansas) 193 Federal, 938. November 28, 1911.

COAL LAND LAWS NOT TO BE FRAUDULENTLY EVADED

Two corporations, disqualified under the coal-land laws from making more than one location, each procured 40 persons to make locations and assign said locations to the corporations in question. The perpetrators of the fraud were indicted for conspiracy to defraud the Government. Held, that the law limiting locations could not be evaded by such subterfuge, and that there was no intention on the part of Congress to except the unsurveyed coal lands of Alaska from the operation of restrictions which apply to surveyed lands.

United States v. Munday, (U. S. Supreme Court) 32 Supreme Court Reporter, 53. December 4, 1911.

COAL LANDS NOT TO BE ACQUIRED UNDER HOMESTEAD LAWS

Where the Government had been induced to patent certain lands containing coal deposits to homesteaders by false and fraudulent proof that the land in question was chiefly valuable for agriculture, the grantee of such patents was held not to be a bona fide purchaser, and the patents were held to be therefore subject to cancellation at the suit of the United States. Coal lands are 'mineral lands' within the United States statutes providing for the sale of the public domain therefore cannot be legally acquired under the homestead laws.

Washington Securities Co. v. United States, (Washington) 194 Federal, 59. February 13, 1912.

Concentrates

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

ONE gram of gold is worth ₧1.329. Silver is variable, but a common value of 1 gram is ₧0.032.

BORAX is used in the enameling industry, which consumes about one-half of the total borax production of the United States. This, according to the Geological Survey, amounted in 1910 to 42,357 short tons, valued at \$1,201,842.

LEAD production in the United States by decennial periods is summarized in 'Metal Statistics' as follows: 1830-9, 122,500 tons; 1840-9, 247,000; 1850-9, 168,000; 1860-9, 153,900; 1870-9, 547,780; 1880-9, 1,345,711; 1890-9, 1,798,294; 1900-9, 3,051,318.

BORAX deposits of the United States are of great extent and there seems to be little danger of their exhaustion. In 1910 the production was, according to the U. S. Geological Survey, 42,357 tons of crude borax, valued at \$1,201,842, while the value of the imports amounted to only \$12,397, approximately 1% of the domestic production.

INCREASE in temperature with depth is a common phenomenon. It is usual to assume an increase of 1° F. for each 65 ft. of depth, but the actual increase is variable. Recorded figures are, 1° F. for each 33 ft. on the Comstock lode; 208 ft., on the Rand; 77 ft. at Bendigo; 80 ft. at Ballarat; 43.5 ft. in the Thames field, New Zealand; 32.8 ft. at Waibi.

CEYLON graphite is well known and widely used. An American firm, Pettinos Bros., of Bethlehem, Pennsylvania, is the principal exporter. With the exception of the operations of this firm and a limited amount of mining on the tea estates, the industry is in the hands of natives. Approximately 50,000 men, women, and children are employed in the industry.

TIN production in 1911 is estimated at 109,600 tons of 2240 lb. each. Of the total, 55,100 tons came from the Straits Settlements, 22,600 from Bolivia, 15,000 from Banka Sales in Holland, and 5300 from Cornwall. The remainder was from Australia, South Africa, Java, China, and the United States. The last is the largest user of tin, but an insignificant producer.

RIPARIAN rights are not recognized in Nevada. Priority of appropriation dates from filing an application with the State Engineer before commencement of work. After approval and publication of the notice in some newspaper by the State Engineer, a certificate is issued which must be filed within thirty days of its issuance both in the county where water is diverted and in the county where used.

ACCIDENTS are more common on night shift than on day shift, and it has been proposed that the midnight shift, in particular, be forbidden. The Royal Commission on Mines in New Zealand, which investigated the matter, came to the conclusion that night work in mines, as elsewhere, "may be more detrimental to men than the day shift, but not so as to warrant us in making any recommendation thereon."

WHERE a broad vein apexes in breadth, partly upon each of the adjoining claims, that is, when the joint boundary line of the claims splits the apex, the extralateral rights go to the senior locator. The locator has the right to follow the vein to which he has extralateral rights into the ground of all mineral locations and entries, whether patented or not, whether of an earlier or later location

than his own; but he must follow the vein from his own ground.

MOLYBDENITE is used in the manufacture of molybdenum steel and for the manufacture of molybdenum salts, which are used in chemical analyses, for fireproofing, as a disinfectant, in the manufacture of glazes, and in coloring leather and rubber. Ferro-molybdenum is also used for electrodes for arc lamps. There is a good market for ores containing 90 to 95% molybdenite at \$400 to \$450 per ton, but the supply is almost entirely drawn from foreign sources, chiefly Australia.

LITHIUM minerals of economic importance are: amblygonite, a fluorophosphate of aluminum and lithium, Li(AlF)PO₄, containing theoretically 7.6 to 9.5% Li; spodumene, a silicate of lithium and aluminum, LiAl(SiO₃)₂, containing theoretically 4.5 to 7% Li; lepidolite, a lithia mica, R₃Al(SiO₃)₃, R₃ being generally Fe, Mg, and Li in varying proportions; and lithophilite, a phosphate of Fe, Mg, and Li containing 8 to 9% Li. All of these minerals occur in workable quantities in the United States, in parts of California, Maine, Massachusetts, New Hampshire, North Carolina, and in the Black Hills of South Dakota.

GEYSERS are hot-water fountains. They occur only in volcanic regions and in acid volcanic rocks. In Iceland and New Zealand the volcanic fires are still active. According to W. H. Weed, geysers occur along lines of drainage, on shores of lakes, or in other situations where meteoric waters naturally seek the surface, and they are fed from meteoric waters that have not penetrated to great depths but have been heated by ascending vapors. The supply of heat is derived from great masses of lava slowly cooling from a former state of incandescence, heating waters which, descending to the hot rocks, ascend as highly heated vapors. The intermittent spouting of geysers is due to the gradual heating of water accumulated in fissures or tubes in the rocks, the only mechanism necessary being a tube, which may or may not have local expansions or chambers.

ALUMINUM and its alloys in automobiles, dirigible balloons, and aeroplanes is in constantly increasing use. In the form of magnalium it is used in the beams of analytical balances, and other new alloys are being constantly brought to public attention. The metal is also employed in paper decorations and for wrapping. It is reported to have been used in the textile industries, where it has been combined with silk, to which it imparts a peculiar brilliancy, particularly adapted to theatrical and ceremonial costumes. It has found and is constantly finding a host of applications in smaller articles of everyday use and ornamentation. The Ordnance Department of the United States Army recently awarded a contract for 60,000 or more aluminum canteens and cups. The metal is now being used in various other ways in the light field equipment of the Army.

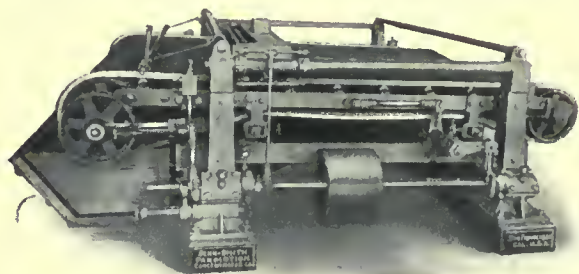

MICA prices vary with the size of the sheet. According to D. B. Sterrett, of the U. S. Geological Survey, it is not possible to give absolute prices of manufactured sheet mica from the lists of dealers, since discounts allowed vary with the nature of the purchases. The prices of the sizes given in the table below are quoted from a standard list for 1911. Discounts ranging from 70 to 10% are allowed on stove mica and from 60 to 10% on electrical mica.

Price per pound quoted for stove and electrical mica for 1911:

Stove Mica.		Electrical Mica.	
Size, in.	Price.	Size, in.	Price.
1½ by 2	\$1.20	1 by 3	\$1.75
2 by 2	2.00	1 by 6	5.50
2 by 3	3.50	1½ by 4	2.75
3 by 3	5.75	2 by 4	3.50
3 by 4	7.00	2 by 7	7.25
4 by 6	9.50	3 by 9	11.00

Pan Motion Concentrator

While the idea of concentration by means of either side or end-shake vanning machines is well known, the combination of both in connection with an endless traveling belt is a new idea. The Senn Pan Motion Concentrator combines a side and end shake into one continuous circular, or pan motion. The results thereby attained are claimed to be greatly superior to those of their side or end-shake machines. The separation of material occurs almost instantly on coming in contact with the belt. The half-circle backward motion of the belt downward gives the heavy particles a chance to settle on the belt, and as the other half-circle going forward uphill starts its motion, the gangue is left behind, and the heavy particles are carried with the belt forward by means of an independent adjustable feed. The belt feed adjustment varies

from 3 to 6 ft. of belt travel per minute to suit the different grades of material.

The machine consists of a lower steel frame, which is suspended from the four stands and an upper frame, rigidly supported on the lower one. The lower frame gets a side shake by means of two eccentrics on the drive-shaft. A third eccentric gives an intermittent forward and backward motion to the upper frame in addition to the side shake given by the lower frame, thereby producing a perfect circular motion of 1½-in. diameter, with every revolution of the drive-shaft. As the feed engages the driving drum only during the forward travel of the frame, any point on the belt describes an advancing circular motion. The machine for a 6-ft. belt covers a floor space of about 9 by 9 ft., is guaranteed for a capacity of from 40 to 50 tons in 24 hours, and a closer saving than known on any existing concentrator. The saving in power, water, wear and tear, and floor space is considerable, compared with the capacity of other machines. The machine is placed on the market by the Senn-Smith Pan Motion Concentrator Co., 1024 Hearst Bldg., San Francisco.

Air-Compressor Lubrication

The lubrication of air-compressors and pneumatic tools is a feature deserving careful attention. A common fault is to use too much oil, and oil that has too low a flash point. An air-compressor does not require as much oil as a steam cylinder, it is better, in fact, to limit the use of oil to a minimum. Oil tends to cause the valves to stick and thereby necessitates frequent cleaning. If kerosene is used to remove the deposit the valves must be taken out, although engineers have been known to introduce kerosene through the air-inlet valves for this purpose. Kerosene will clean the valves, but it is also equally effective in producing an explosion.

The sanest method is to lubricate air-compressor cylinders with soapy water and flake graphite. Such a mixture provides economical, efficient, and safe lubrication and keeps valves clean. A little oil should be introduced when shutting down the compressor to prevent any tendency of the soap-suds to cause rusting. By this method all dangers attending the use of oil are overcome. Flake graphite has a strong tendency to attach itself to metal surfaces, and, when thoroughly worked into the inequalities of surfaces, imparts a superficial glaze or veneer of great smoothness, high polish, and endurance that prevents actual contact of metal to

metal, and make it possible for relatively small quantities of fluid lubricants to provide a safe and sufficient film or lubricating layer.

Flake graphite is an inert mineral; its normal smoothness is quite unaffected by any degree of heat attainable in the air-compressor cylinder. Under no conditions can it be volatilized, carbonized, or baked into a hard or gummy mass to interfere with the free action of the valves. On the contrary, its presence upon working surfaces is a guarantee of smooth operation. One of the best booklets on the subject is 'Air Compressor Lubrication,' published by the Joseph Dixon Crucible Co., Jersey City, N. J. Everyone in any way interested in the operation of compressors should read this booklet. Copies may be obtained from the above company upon request.

Commercial Paragraphs

The REDWOOD MANUFACTURERS Co. of San Francisco has completed the erection of the wooden tanks at the new mill of the Tonopah Belmont Development Co. at Tonopah.

W. P. Dinsmoor, for several years manager of the SULLIVAN MACHINERY Co. at Denver, Colorado, has been appointed manager of the Chicago sales office. George W. Blackington, associated with the general offices of the company at Chicago for several years as general sales manager, will succeed Mr. Dinsmoor in charge of the Denver office.

The TAYLOR IRON & STEEL Co., High Bridge, New Jersey, has within the last few years entered into the manufacture of the standard types of chain in manganese steel. As compared with the ordinary iron and steel chains, the manganese chain is said to last longer, especially in handling gritty and abrasive materials. It has resulted in reducing the items of breakage or renewal of equipment, so that in spite of its higher initial cost the new chain is cheaper in the long run. The detachable type of chain was the first to be perfected in this material. On account of difficulties encountered in casting, it was not practical to make any smaller size than the No. 88, but this size and the larger ones are now on the market. Many special chains are now being made, and practically all of the standard types for conveying and elevating work can also be procured. Sprockets or traction wheels are made in manganese steel for all of the various types of chains, and the results secured are said to be fully as good as those obtained from the chain.

The following interesting figures showing the consumption of hides in one large shoe factory were submitted by the F. MAYER BOOT & SHOE Co., manufacturers of the well known Mayer Honorbilt Shoes. These figures cover one year's operation in the big Mayer shoe factory at Milwaukee: Total number of hides consumed last year, 382,573, divided as follows: 55,447 steers, 28,676 cows, 51,602 calves, 62,160 sheep, 2320 horses, 1360 kangaroo, 181,008 goats. All these animals placed in a single file would make an unbroken line reaching from Chicago to Detroit. The requirements for one day's operation make a line over a mile long. To work this quantity of hides into shoes requires over a thousand people, who draw enough wages to keep a city of 5000 people well fed and happy. Milwaukee, Wisconsin, where the factories of the F. Mayer Boot & Shoe Co. are situated, is the greatest leather market in the world, affording this company advantages in the selection of hides, one reason for the superiority of its product. This company is a large manufacturer of miners' boots.

An interesting booklet has just been issued by the HYATT ROLLER BEARING Co. of Newark, New Jersey, which illustrates twelve standard makes of mine-car wheels now equipped with the Hyatt type of roller bearing. Each make of wheel is illustrated in cross-section, showing the details of its construction, and a brief but comprehensive description of each type is also given. The information contained in this booklet should be of great interest and value to any mine operator or superintendent.

EDITORIAL

A PUBLIC personage has declared, "I used to think that Roosevelt was crazy, but I have come to the conclusion the public is." Everything gets handed on to the ultimate consumer these days.

REVOLUTIONS make business for bankers. Mexico is borrowing \$10,000,000 in the United States, and China has taken the first installment of her \$300,000,000 international loan.

MONEY made in mining finds its way into all the avenues of industry, and beyond. Some \$15,000,000 from South Africa is to go to various charities by virtue of the will of Sir Julius Charles Wernher.

CORNELL UNIVERSITY has been given a sufficient sum to provide new shops for the mechanical department, and it is most appropriate that this gift, by Mrs. F. O. R. Rand, is to be a memorial to J. R. Rand and his son, who have done so much in application of mechanical engineering to industry.

ORGANIZATION of the Canadian Mining & Exploration Company, with a paid-up capital of \$2,500,000, is a notable event in Canadian mining. The personnel of the company augurs well for its success, and not the least of its assets is an engineer so well qualified as Mr. W. W. Mein.

SEARCH for tin in the United States has been conspicuously unsuccessful, despite the large demand and high price obtaining. Last season Seward Peninsula placers produced a small tonnage at good profit, and it is now reported that a great tin-bearing lode has been discovered in the Hot Springs district of the Tanana valley. Confirmation of this report would be the best of good news not only for Alaska but the whole country.

AN interesting suggestion growing out of the *Titanic* disaster, is that of Mr. Lewis Nixon, in the *North American Review*, that lifeboats be housed over to make their launching safer, fitted with automobile engines, and lowered by their own power. As Mr. Nixon says, there are now more men who know how to run an automobile than to pull a boat, though it takes a striking statement such as this to remind us how far we have gone on the road from muscle to machinery.

NOME is again in touch with the rest of the world by steamer, and what promises to be a particularly busy season has opened. One firm has contracts for erecting five dredges, and other work is under way. The revenue cutter *Bear* arrived June 3 with the winter's accumulation of mail, and diggers in the drift can now read up on the 'muck-raking' magazines. The *Bear* reports no ice, and the route has been opened unusually early. The *Umatilla* sailed from San Francisco June 1, the *Victoria* from Seattle the next day, and the *Senator* and others later. This annual rush to Nome is one of the events of the year and all the steamers were crowded. Late comers had to stand aside because of the new rule regarding life-boat accommodation, but there

were no restrictions as to fresh vegetables. At Nome in the spring there is a hearty welcome for all heads, be they human, lettuce, or cabbage.

SIMPLE individual problems become difficult when grouped, according to the old fable of the bundle of sticks, and the metallurgist is not lacking in pertinent examples within his own field of work. One of these is illustrated in the investigation by Mr. Will H. Coghill, which is concluded in this week's issue, where the association of silver with oxides of manganese render it unamenable to cyanidation. The remedy is apparently simple; to subject the ore to a preliminary reducing action; but the securing of a cheap and efficient method of doing this opens a field for investigation. Numerous other instances at once occur; the association of pyrite, chalcopyrite, and zinc-blende, the occurrence of barite in ores, tetrahedrite as an associate of silver, and titanite in iron ores, to name but a few. The importance of mineral associations does not always receive the attention it deserves in studies in economic geology, and mineral colligation might well be elevated to the rank of subdivision of the general topic of economic geology, and studied at some length. The problems of technical work are daily becoming more complex, by the solution of the simple problems, and technical schools continually feel the pressure to equip with a more adequate training men to solve these as they arise. The best equipment is that founded on accurate and thorough training in the basic principles of scientific work. for the experienced civil engineer may find himself called upon to manage a mine, while the mining engineer is commonly called upon to solve problems in civil, mechanical, electrical, and chemical engineering in the practice of his profession.

Metallurgy and the Rand

American metallurgists are highly complimented in an article on 'Metallurgical Progress on the Rand' appearing in *The South African Mining Journal*, April 13. That there has been great improvement in Rand practice is evidenced by the decrease in cost and increase in recovery from the 85 to 86 per cent of pre-war days, to the 95 to 96 per cent obtaining at present. Despite this, our contemporary points out that technical progress on the Rand has been due more to adoption of devices invented elsewhere, particularly in America, than to local invention. The work of Mr. W. A. Caldecott is cited as exceptional, and indeed his contributions to technology have deserved and received wide recognition. In the main, it is insisted, recent improvements in cyanide practice have come from America. Pachuca agitators, Merrill filter-presses, and Merrill zinc-dust precipitation, Trent agitators, Dorr slime thickeners, are all quoted in evidence. The work at the Portland mill at Colorado Springs, including the building of large revolving-drum filters, giving better washing and deeper submergence of solution, is an instance of the activity of American metallurgists in improvement of cyanidation. Such recognition coming from a foreign technical journal of high standing is flattering. To the list cited by the *Journal* many names might be added, for the metallurgists of North America, including the United States and Mexico, have, in fact, made important contributions to cyanide practice. They have made the process practical under widely different conditions, and, what is more to the point, they continue to devise and invent.

If American engineers have been more inventive than those of South Africa, something must be credited to the genius of the people, and something to differences in conditions. At first glance it would seem that South Africa and North America offer the same inducements to inven-

tion. Both are still in the stage of pioneering, both have been settled by mixed races. New conditions are met in each land by men of many types and of widely varying experiences. In the long run the Union of South Africa and the United States of America seem sure to develop much in common. At present they are both great mining countries. When the possibilities of South Africa come to be recognized and the attitude of the people toward colonists changes slightly, reclamation will make possible there, as in the Western United States, a large agricultural development. At present the burghers look upon the division and sale of land as almost treasonable, and in the absence of a working population of small land-owners, physical labor by white men around the mines is discouraged. Men become inventors because of the wish to minimize their work, and where it is possible to "let George do it" there has not been the acute personal incentive to perfect a machine. There being no necessity, few inventions have been born.

Other important factors, relating to gold-mining especially, have been the organization of the industry and the simplicity and great size of the Rand orebodies. It was early seen that the field was unique in the security offered as to amount and uniformity of ore reserves. Any standard practice was profitable, and methods soon reached a degree of perfection that assured a good profit. The rush was then toward large-scale operations. On this the only check has proved to be the limited supply of native labor. In the development of the Rand the London share market has been the controlling motive. Anything which threatened the immediate price of shares was not to be thought of, however much it might promise for the future. The great scale of operations made any change in treatment expensive, and, if the new plan proved unsuccessful, thousands of dollars would be lost before the result could be determined. In the meantime shares would have been unsettled; and that fact was kept always before the Rand manager. These difficulties are successfully met elsewhere and might, we believe, have been better met on the Rand. At the Alaska Treadwell, after the cyanidation plant was completed, a question arose as to whether it would not be better to abandon amalgamation and send all material directly over vanners to the cyanide plant. To test the matter, 20 stamps were at once set aside and the flow was rearranged on the new plan. These stamps have now been fed for nearly a year with the same ore as has gone to the 20 next them operating according to the ordinary plan. In a short time it will be possible to tell exactly whether the new or old plan is better, and in the meantime routine operations have not been interrupted. While tests on a large scale have been run on the Rand, not enough of such work has been done, and in general it has been merely the trying out of practice developed elsewhere. Even in this there has been surprising conservatism. Butters filters, despite Mr. Charles Butters' intimate connection with Rand affairs, have only just been introduced, and only now, under the guidance of Mr. F. L. Bosqui, is zinc-dust precipitation coming into its own in South Africa. The margin of possible additional saving on the Rand is admittedly small, and the necessary capital expenditure considerable, but the tonnage still to be treated is enormous, and nothing less than the best should be tolerated. Cyanidation was first successful on a large scale on the Rand, and we would not rate the contributions to metallurgical progress made by Rand metallurgists as low as does our South African contemporary, but still it has been less than is in consonance with the magnificent scale of things in the world's greatest goldfield, and there has been far too much of truth in current gibes at the 'crusted conservatism' of the Rand. The field is no longer young; a generation, as

professional practice goes, has been trained in South Africa; practice in South Africa has borrowed heavily from all the world, and payment should be more in kind and not alone in coin.

Courtesy and Etiquette

Courtesy, like morality, is partly basic and partly customary. Certain acts are fundamentally right and wrong, others are merely inexpedient, but the distinction is not always clearly made. A serviceable definition of etiquette is that it is customary courtesy, a convenient catalogue of actions that experience has shown to be generally desirable or undesirable, so that relations with others may be guided without the necessity for deciding each case upon its individual merits. Curiously enough, etiquette is frequently designated courtesy, and we speak of the professional courtesy between physicians, engineers, and other professional men, meaning thereby such customary relations as experience has shown to produce the maximum of mutual satisfaction and convenience. Those whose work is along professional lines are necessarily aware of these relations and the reasons therefor, though to an outsider they may appear strange and, at first sight, even unreasonable. The etiquette of the engineering profession has been much discussed, and it is our present purpose to refer at some length to the etiquette of journalism and literature, a field in which customary courtesy is no less important from being frequently misunderstood or overlooked. To the experienced writer it is already familiar, but to those whose ventures into authorship are but occasional and infrequent some further discussion will be useful.

Perhaps the commonest breach of journalistic etiquette is the sending of anonymous contributions. This is a breach of the post-office regulations, as well as of etiquette, and is entirely unnecessary, in addition. Under certain circumstances it may be undesirable for an author to attach his name to an article or letter containing information of sufficient interest and usefulness to the profession to justify its publication. Such being the case, it is not only possible but proper to obscure the identity of the author behind a *nom de plume*, while securing the benefit of his contribution. But in every such instance the writer must be known to the editor, otherwise opportunity would be afforded for those so disposed to say covertly what they are unwilling to allege openly, and unpleasant situations and legal complications may arise. Every communication sent to a periodical must therefore have the author's name attached. Whenever it is requested for good reason that the true name be not published it will be withheld.

Another convention frequently ignored is that requiring that corrections or criticisms shall be sent to the periodical in which their object appeared. Where criticism is not personal in character or apparently actuated by motives other than a desire for accuracy, and contains useful information, it is rare for a journal to refuse to accord it equal prominence with the article or statement criticized. When criticism is addressed elsewhere, the critic both ignores the conventions of common courtesy and journalistic etiquette, and fails to secure the attention of the larger number of those who may have read the statement criticized. Any criticism of a statement of fact should invariably be published in the journal in which the misstatement appeared, otherwise students or investigators may later come upon the erroneous statement, but fail to find its correction, and thereby be misled.

In matters of usage and style, etiquette is important, the more so because frequently, almost commonly, it fails to be recognized. The practised writer gradually forms a style of writing which is peculiarly his own and which is graceful, pleasing, and accurate to a greater or less degree, according

to his measure of skill and experience. It is not so commonly known that all the more important journals have also a style of their own, founded not only upon the opinion of the editorial staff as to what is preferable, but also upon mechanical considerations necessarily taken into account if uniformity of appearance, and the securing of accuracy and efficiency in composition and proof-reading, is to result. Whether 'program' is spelled with or without a final 'me' is largely a matter of individual preference, but to spell it both ways upon the same page not only produces an unattractive appearance, but reacts to produce a careless habit of mind that will bear fruit in inaccuracy in matters of more importance. As a guide to authors, editors, composers, and proof-readers, the University of Chicago Press, for example, has prepared a 150-page 'Manual of Style,' and the proof-readers associations of the larger cities have adopted voluminous regulations, which might, from an engineering standpoint, be called specifications, as to spelling, punctuation, and other matters of usage in style. The style followed by the *Mining and Scientific Press* is essentially that developed in 'A Guide to Technical Writing,' by Mr. T. A. Rickard. It follows, therefore, that the style of an article as it appears in print conforms to that of the journal in which it is printed rather than that of its author, if the two conflict. To most authors this is not a matter of importance, but others who take pride in their peculiar style, sometimes feel a sense of injury at changes made in their contributions. This is natural but unwarranted. It is not practicable for a journal to change its style to suit the individual wishes of its contributors any more than it is practicable for a street-car to stop before any house along the line in order to suit the individual convenience of a patron.

Since the introduction of the typewriter and carbon paper the submitting of manuscript to more than one journal at a time has become a not infrequent breach of journalistic etiquette, which doubtless arises from a lack of precision of ideas in regard to the publication of an article in more than one journal. Addresses and statements by those in authority, either by reason of office or professional standing, are likely to contain so much of interest and value as to warrant publication as widely as possible. Scientific investigations, similarly, may justify republication, and it is customary in such cases for the author to ask permission to republish elsewhere, which is almost invariably accorded. This is so well recognized that weekly scientific journals commonly publish excerpts and abstracts from the proceedings of learned societies, with the usual footnote of acknowledgement, without waiting to secure permission to do so. The publication of any article depends upon a variety of considerations, and it may easily happen that when an article is submitted to two journals simultaneously it may be accepted by both, whereas neither would have accepted it knowing that it would be published elsewhere. Convention requires that manuscript should be submitted to only one journal at a time, and where this is productive of too great inconvenience, as in the case of engineers living in remote places, it is possible and proper to endorse upon the manuscript that if it cannot be accepted for publication within a given period it will be submitted to another journal; any editor will be glad to observe the author's wishes in this regard.

Many other points of journalistic etiquette can receive but the briefest mention. Technical journals differ from daily papers in many respects, and the best way to prevent information leaking out, is to accord it freely, with a request that it be withheld from publication. Where it is desired that information be not given out before a certain date it should be so marked, and the request will invariably be respected. But the best guide as to the observance of journalistic etiquette is innate courtesy, aided by an intelligent observation of the usage of others.

Genesis of Silver-Lead Ores in Wardner District, Idaho—II

By OSCAR H. HERSHEY

SULLIVAN PYRITE DISSEMINATION

Most of the rock in what may be called the 'vein zone' in the Sullivan, Bunker Hill, and Last Chance mines has a rather dark gray color which is generally due solely to the dissemination of fine-grained pyrite. The microscope shows that the grains have good crystal outlines and many of them are perfect cubes. They are perhaps most abundant in the sericitic matrix, but also occur in the quartz grains. This is another case of metasomatic replacement, and it has occurred on a large scale for it is present in practically all the Lower Revett quartzite between the Sullivan and Buckeye faults, though in places it is so light that the rock retains its white color, and in other places it is so abundant that the rock appears like a very fine grained aggregate of solid pyrite. Going northwestward between the Sullivan and Buckeye faults, the Lower Revett is succeeded by Upper Burke strata. The first 600 to 900 ft. is largely 'white Burke' in which there is little disseminated pyrite, then comes a band of distinctly, but not very strongly pyritic rock, followed by a narrower band in which the disseminated pyrite is fairly strong, the whole having an average width of about 1500 ft. Beyond that is barren light-colored rock. The most favorable rock is the lightly sericitic quartzite of the Lower Revett.

I regard the Sullivan fault as the original foot-wall limit to this pyrite replacement, because the heavy dissemination generally thins rapidly in the few feet of sheared rock over the gouge, gets a further marked decrease at the gouge, and beyond that occurs only as a light, irregular fringe not usually extending more than 10 or 15 ft. beyond the gouge. On the hanging-wall side, the pyrite extended in places much beyond the Ollie McMillin fault, and the Buckeye fault marks the approximate limit, though it is more recent in age. The country beyond the vicinity of these faults has some pyrite, but it is sporadically distributed and is of a different type. The pyrite zone is of the nature of the 'fahlbands' so common in some districts. The main portion of it is a block of Lower Revett quartzite which, before faulting by the Cate faults, was at least 4000 ft. long and a large part of it 800 to 1200 ft. wide, dipping southward with the bounding faults. The amount of pyrite apparently does not change in a vertical depth of 1200 ft. or what was, before the Cate faulting, 2500 ft. Generally the mineralization was exclusively pyrite, but I am not certain that disseminated siderite that occurs in parts of the zone is not genetically related to the pyrite. The pyrite is clearly older than any lead mineralization that has produced commercial orebodies. Further, most of the fault gouges in the mines owe their dark color to grinding of the pyritic rock. In fact, the thorough distribution of the pyrite in the zone required the absence from that zone of any strong gouges or zones of shearing.

In constructing sections, it became apparent that most of this block differs structurally from any other of the district in that it is the only one in which the Lower Revett stands a fair chance of persisting to very great depth. It was thrust, by the Ollie McMillin fault, whose displacement may be over 10,000 ft., far down into the Priehard slate, so deep that perhaps it reached the zone of flowage and became impermeated by hot solutions under great pressure which ascended along the beds. Indeed, it may have reached the vicinity of the monzonitic magma and the ascending solutions may have come from the superheated zone near the magma. The iron may have been derived from the iron carbonate so abundant in the rocks of the region and sulphur may have been supplied by the magma in the form of hydrogen sulphide emanations. It is true, also, that the Priehard formation may have furnished the necessary constituents, and magmatic influence is not indispensable. The solutions did not at depth come into contact with any rocks

bearing lead and zinc, although the disseminated lead and zinc deposits were already in existence in a neighboring block and the two mineralizations overlap in the Middle Blue Bird tunnel. The solutions broke through the small Ollie McMillin gouge and also penetrated into the Upper Burke within the zone until the physical characters of the strata became too unfavorable.

PHIL SHERIDAN TYPE

The Phil Sheridan mineralization consists chiefly of siderite and coarse pyrite, with subordinate amounts of quartz and zincblende, but no galena. Its outcrops consist of cavernous masses of limonite with a skeleton of quartzite fragments and quartz seams. This usually yields, upon assay, a little zinc and silver, and sometimes traces of gold, but little or no lead. The masses are usually without definite limiting features, grading irregularly into the unaltered quartzite, but in a few places they may be limited on one side by a fault gouge. The quartzite fragments remaining in the mineral masses do not usually have the character of those of an ordinary breccia and the relation between them and the iron minerals suggests, as pointed out by R. D. George, metasomatic replacement. Even where the Phil Sheridan minerals constitute the bulk of the rock, the original bedding planes are apparent. The quartzite fragments have disseminated pyrite as in the same beds at a distance from the Phil Sheridan bodies. I am inclined to see a close relation between the two types of mineralization, the Phil Sheridan perhaps representing the extreme phase of the replacement process, of which the Sullivan dissemination of pyrite is a weaker and earlier phase.

A large body of oxidized Phil Sheridan mineralization occupies a zone 100 to 150 ft. wide, paralleling the Hoffman fault on the south side. Samples have assayed up to 6.60 oz. silver per ton and one yielded 0.5% zinc. I have seen a little chalcopyrite in places. Bunches of limonite are distributed thence northwest along the Buckeye fault in a zone mostly 80 to 140 ft. wide to the centre line of the Last Chance claim. Down through the Last Chance and Bunker Hill mines, this zone may be seen at a number of points. It occupies the hanging-wall side of the vein zone and where it sets in the lead-bearing ground practically ceases. It is a characteristic of the Phil Sheridan bodies that they tend to have an oblique position in the vein zone, diverging from the foot-wall toward the west.

Southeast of the Hoffman fault it is widely distributed within the vein zone, but its strongest development was in a comparatively narrow zone accompanying the Motor seam. Thence eastward Phil Sheridan bodies are scattered as far as the vein zone may be traced. The outcrop of one is said to assay 3 or 4 oz. silver per ton, but no lead. Another is associated with several thin nearly vertical fault gouges. Some of it is said to assay 5 to 6 oz. silver per ton and no lead. Several bunches of quartz, chalcopyrite, and argentiferous tetrahedrite, some of which assayed 42.8 oz. silver per ton and 8.66% copper, with no lead or gold, are probably special concentrations of the copper and silver minerals that are present sparingly in the siderite-pyrite bodies, and elsewhere; also, the silver appears to be in association with tetrahedrite.

The Phil Sheridan mineralization seems to characterize an east-southeast belt that lies two miles south of the South Fork of the Coeur d'Alene river from Kellogg to Mullan. On Placer creek a tunnel exposes large irregular bodies, largely of siderite, some pyrite, a trace of copper minerals, but practically no lead. A siderite zone said to average 100 ft. wide and traceable 17,500 ft., south of Mullan, seems to be essentially barren of lead. I have seen small bodies near the Polaris mine and at three prospects in Moon gulch. In short, the Phil Sheridan mineralization may have been widely developed in the Coeur d'Alene dis-

triet in connection with the east-southeast faults of the second system, in a period preceeding the formation of commercial orebodies, and many large outcrops of limonite and quartz are of no prospective value because they do not go down into Phil Sheridan mineralization. The Phil Sheridan solutions generally did not come into contact with lead or else they were chemically unfitted to dissolve and redeposit it. The latter is improbable, especially as they were able to handle zinc.

BLUE BIRD TYPE

The Blue Bird ores are characterized by the presence of considerable pyrite. Local variations, which will be described separately, may not all be of the same age, but they apparently represent a distinct stage of mineralization succeeding the Phil Sheridan stage. They are connected genetically with the reverse faults of the fourth system. The Government Gulch, Elk Creek, West Fork, and Big Creek (as mapped) faults, all normal, with north-northwest courses, nearly vertical dips, and downthrow on the east of 2700 ft. in one case and probably more in the others, constitute the third system, due to progressive subsidence toward the east or progressive uplift toward the west. The Jackson, Buckeye, Oakland, and Norman are the principal faults of the fourth system and mark a series of thrusts from the southwest. Subsidiary faults, of displacement varying from 25 to 200 ft., include the Sierra Nevada, Caledonia, Viola, Motor, McNally, Williams, East, Bryan, Governor, and seams 'A,' 'B,' 'C,' and 'D.' The Blue Bird ores are connected with the small faults rather than the more important ones.

Small seams and pockets of pyrite, zincblende, and galena are scattered through a block between the Upper Cate and Buckeye faults, under Blue Bird gulch. The percentage of zincblende is unusually high, even for the Blue Bird type; fine-grained dark brown blende is as abundant as the galena. This is also the block in which the disseminated zinc and lead deposits enter the region of Blue Bird seams and pockets. The natural inference is that the Blue Bird blende and galena were derived from the disseminated deposits, the latter being notably richer in blende than galena. Elsewhere in the mines where the Blue Bird ores are farther from the disseminated deposits, the percentage of galena is higher. It is a matter of common observation in the Coeur d'Alene district that veins become proportionally richer in sphalerite with depth, presumably toward the source. I consider that we have here evidence pointing toward the disseminated zinc and lead mineralization as the source of the lead and zinc of the Blue Bird orebodies. The pyrite may have come from the Sullivan pyrite dissemination and the relatively small amount of siderite present from the disseminated siderite. Thus we have, in earlier mineralizations, the elements of the Blue Bird and all we need is a new set of fractures to change the course of the ascending currents and cause the deposition of galena in a zone in which formerly deposits free from it were formed. The Blue Bird solutions primarily circulated along cracks in the quartzite, possibly attacking the walls somewhat; but it is true throughout the mines, with one important exception, that fissure filling and not metasomatic replacement of quartzite was the predominant characteristic of the Blue Bird stage. It is a curious fact that, with one notable exception, the Motor zone, the solutions avoided the large bodies of Phil Sheridan mineralization; the latter cemented the rock into masses that were not easily broken, and so were generally impermeable to the Blue Bird solutions.

The most important development of the Blue Bird type is in the block bounded by the Buckeye, Hoffman, Upper Cate, and Lower Cate faults and extending also into the Upper Burke beyond the Tyler fault. The hanging-wall limit is the large body of Phil Sheridan mineralization until it dies out, and thence the Buckeye fault to the Lower

Cate fault. This great mass of rock, which, near the surface, is about 3500 ft. long and mostly 200 to 500 ft. wide, is traversed by a network of galena-bearing veinlets that, collectively, constitute a gigantic 'stringer lead.' They are connected with a series of small faults whose prevailing course is about N. 70° W., practically parallel to the strike of the bedding planes. Some of them are only bedding plane slips, though most of them cut the bedding at small angles and are much steeper than the Cate faults. A characteristic feature, especially in the Last Chance mine, is the presence of many veinlets of ribbon quartz. The quartz is of a fine-grained, hard, slightly bluish type. A rather fine-grained pyrite, a rather light-colored zincblende, some galena, and a little siderite, tend to be distributed along fine parallel lines, giving the rock a banded appearance.

The seams vary from a fraction of an inch to 30 inches in thickness. They generally strike approximately parallel to the small faults mentioned above, but dip at much lower angles, 30° or even less being quite common. Any one seam cannot be followed far on the dip, but as

BUCKEYE FAULT.
(Photo by W. J. Elmendorf.)

they occur in unbroken succession one above another, stopes can be carried up on them, these stopes being much steeper than the individual seams. The ribbon seams were certainly deposited in open fissures; they were produced by slight movements along the small steep gouge seams, which cracked the intervening brittle quartzite, and dragged the blocks apart, making a 'giant breccia' through which water circulated readily until the fissures were cemented. The fact that the seams are so much flatter than the faults indicates that the movement along the steep gouge seams was an upward thrust of the hanging-wall side. The pyritic Lower Revett yielded more open fissures than the softer Upper Burke.

In large portions of the block, particularly toward the hanging-wall side, the seams are too small and widely separated to permit of mining. They increase in size and numbers, until the amount of waste required to be handled is small enough to permit of profitable stoping. In some of the stopes the individual seams are followed, but in others the mineralization has proceeded to such an extent as to make a veritable breccia of quartzite and ore minerals, and then large chambers are opened. In the larger and better shoots there are cores in which the ore is very rich, in places considerable bodies of nearly pure galena. The roof of the Drew stope in the Last Chance mine at one time appeared to have practically solid galena 10 by 15 ft. in cross-section. In this Drew area, it is evident that the mineralization was effected in two stages; the lower grade ore is ordinary Blue Bird with pyrite and blende quite noticeable, but the higher-grade ore is chiefly galena with some siderite.

In short, the so-called ore-shoots of this block have a commercial limit, that is, there is merely a gradual fading of the degree of seaming, except in a few places where the N. 70° W. seams cause a decided decrease in the ore-seams or where post-mineral faulting has brought rich ground against poor. Changing economic conditions will enlarge or decrease the size of the shoots. Four principal shoots or rich cores may be made out. They pitch about S. 50° W. When considered in relation to the seams of the N. 70° W. system with which they are connected, they are seen to stand *en echelon* to each other, being intimately related to the foot-wall limit of the Blue Bird zone, whereas the gouge seams are oblique to that limit, having been controlled largely by the bedding. The details of these ore-shoots would unreasonably lengthen this paper. The most eastward, the Hatton, has been stoped from the surface to the Cedar level of the Bunker Hill mine and has produced about 160,000 tons of ore. A great group of more or less connected stopes represents the Roberts shoot which extends from the surface to a vertical depth of about 700 ft., and has probably produced about 600,000 tons of ore. The heart of the Fan ore-shoot was one of the most persistent and straightest orebodies in the district and is represented by a nearly continuous series of large filled stopes in the Last Chance mine and a new stope in the Bunker Hill mine. It extends from the base of the oxidized zone to a vertical depth of 1000 ft. and has produced probably over 600,000 tons of ore. The most westward shoot, the Edna, is exceedingly irregular, but can be traced from the base of the zone of oxidation to a vertical depth of 1300 ft., and to that depth will produce probably 150,000 tons of ore.

The block of Lower Revett quartzite lying southeast of the Flint fault, and between the Motor and Sullivan faults, contains seams and orebodies of Blue Bird type that lie in zones that strike W. to N. 70° W. and are relatively steep. As they are much steeper than the Motor seam, they must enter the Phil Sheridan zone that accompanies that seam. The solutions while arising in the steep seams, upon reaching the large body of siderite and pyrite of the Motor zone, would naturally attack it and replace much of the siderite by galena, blende, and other Blue Bird minerals. On the No. 9 level of the Sullivan mine, the Motor zone is exclusively Phil Sheridan mineralization, and a group of Blue Bird seams lies under it. They first reach the zone in the Morgan raise and begin to form an orebody of the Motor system. This, at first, is very small. The solutions, once introduced into the zone, were able to spread as they ascended. For this reason, the orebodies lengthen upward. Other steep Blue Bird seams reached the Motor zone at higher levels farther west and started new ore-shoots upward in the zone. The solutions were at first confined to the lower part of the siderite-pyrite zone under the present seam, but as they ascended they penetrated higher in the zone until no part of it was free from them. The main current continued up along the Motor seam and formed a great orebody that has been mined up to the zone of oxidation. A little of the Phil Sheridan mineralization was missed in places. Practically all of the Motor ore, amounting to over 700,000 tons already mined, I attribute to the solutions introduced into the Motor zone by the most southeastward belt of Blue Bird seams. The explanation is such a simple and rational one that it hardly admits of doubt. Furthermore, it constitutes the best evidence that the solutions that deposited the Blue Bird type of ore were ascending.

The total amount of ore of the Blue Bird type produced by the two companies in whose mines it occurs may have been over 2,500,000 tons. It is a magnificent showing for this type of mineralization.

BUCKEYE TYPE

The Buckeye is a product of the Blue Bird stage that is confined to the vicinity of the Buckeye fault and consists chiefly of coarse grained dull lusted pyrite containing clusters of moderately fine grained galena that, either by crushing or part decomposition, readily breaks down into a powdery black substance. Dark brown fine-grained blende may be present. In the vicinity of the disseminated zinc

and lead deposits (which the Buckeye fault has brecciated) assays range up to 11% lead, but no commercial orebodies have been developed on this type.

ONTARIO TYPE

Faulted areas of the 'vein zone' may be found northwest of where the Cate faults first cut off that zone. They are occupied by Upper Burke strata, most of which is barren and light-colored, but here and there, especially in the bands of white heavy-bedded brittle quartzites and along the Cheyenne and Ontario Footwall faults, there are irregular bodies of Ontario type whose mineralization varies from a light stain along cracks to bodies of good grade ore, tons in amount, as on the Ontario Deep level. This ore is a breccia of non-pyritic quartzite cemented by rather fine grained galena, with a little white quartz in seams and pockets and traces of blende. Southeastward, it passes through a phase rich in fine-grained pyrite into typical Blue Bird seams. The Ontario gets its character from being deposited beyond the zone of disseminated pyrite. It is sporadically developed throughout the mineral belt from Deadwood to Corrigan gulch.

The fifth system of faults, including the Iron Hill, Bulah, and Last Chance, the first with a probable displacement of 1000 ft., are simple gravity faults that may be due to lengthening of the area through a general bulging up of the whole Coeur d'Alene region. The sixth system is made up of a number of normal faults of small displacement that cut the Blue Bird orebodies. They include the Fan, Cloke, Dago, Rowe, Sanger, McGatlin, and Lackawana 'seams,' some of which do not reach the surface. They were probably due to slight subsidence toward the southwest. Compression again came into play and the faults of the seventh system may be due to a slight thrust from the south.

JERSEY TYPE

Under this heading I will describe a system of veins that have courses generally lying between east and northeast and, with a few exceptions, dips south to southeast. They are commonly known in the district as 'fissures'; they are more like the quartz veins of other districts than are any other of the Wardner orebodies. They are the product of a distinct set of fractures, largely thrust faults (the seventh system) of comparatively small throw, quite at variance with those of earlier and later periods. They are very crooked and badly cut by post-mineral faults generally of small throw, but the great pitching troughs and arches are probably original. Quartz and galena are the predominating minerals; more or less brown zincblende is generally present and a little chalcopyrite and tetrahedrite. Siderite is common, though not conspicuous, and pyrite is present only in small amount. A characteristic feature is a relatively high silver ratio, apparently due largely to argentiferous tetrahedrite. Besides the fissure proper, there is generally much galena scattered in seams and pockets in a zone 10 to 50 ft. wide on one or both sides of the quartz vein and, in the better stopes, much of the ore comes from this breccia.

The Jersey fissure, which has been extensively mined in the Last Chance mine and is now being stoped in the Bunker Hill mine, originally extended from the vicinity of the Sullivan fault to beyond the Buckeye fault. Starting at the surface in Upper Burke strata, with depth it passes the Tyler fault into the hard pyritic Lower Revett. It has a dark gray to black gouge. A typical specimen of Jersey ore consists of a breccia of white quartz fragments cemented by galena and other minerals. Where the quartz greatly predominated it is likely to be a thoroughly shattered mass with galena developed along the cracks. Sometimes pebble-like pieces of quartz may be picked from the galena, leaving a rounded cast. There were evidently two stages in its formation: in the first the hard white quartz vein was formed without much galena. Subsequent movement along the fault shattered the quartz and enabled galena-depositing solutions to ascend along it. The main ore-shoot averages several hundred feet in length and is clearly traceable from Bunker Hill No. 9 level to the Last Chance O level, 2000 ft. on the dip. It has a straight course, almost due south, which is practically straight

down on the dip of the vein as a whole. In ascending, the main ore-shoot gradually improved to a point a little below where it passed from Lower Revett into Upper Burke quartzite, and thence there was a gradual decrease. This was connected with the development of a great concave curve which becomes of less radius as height is attained. This favored the maximum of crushing of the quartz vein and neighboring quartzite. The production of the Jersey fissure when it has been exhausted down to Bunker Hill No. 9 level will considerably exceed 400,000 tons.

The Francis vein is known only below Bunker Hill No. 9 level. It originally ended near the Sullivan fault; it extends thence to the Lower Cate fault, which has cut and dragged it northwestward. It has a small blue-gray gouge like that always found with the Jersey fissure. The ore consists of much-shattered white vein quartz cemented by sulphides and siderite. Subsequent movement has granulated and sheared much of the galena near the gouge, so that it now appears as extremely fine-grained steel-gray bodies, often a foot thick. The zineblende in places is in irregular brown patches as much as 6 in. or 1 ft. thick. There is in places very rich lead ore several feet in thickness, besides bunches of coarse galena in the neighboring quartzite. There is a well-defined main ore-shoot between 250 and 300 ft. long which is apparently related to a sharp bend in the fissure, making of it a steeply pitching anticline. There is much additional stoping ground. Because the Jersey and Francis have the same general strike and direction of dip, are identical in structural and mineralogical characters, and may be fitted together in a manner supported by other features of the vein zone, I consider them parts of one vein faulted by the Cate faults. This vein passes obliquely through ore-shoots of the Blue Bird type without any of the characteristic seams of the latter cutting it; hence it represents a distinctly younger stage of mineralization. It may have derived its galena at great depth from the Blue Bird ore seams and it probably will yield more or less ore until it passes entirely to the eastward of the Blue Bird ground.

The Barr fissure lies over and is approximately parallel to the Francis fissure, though uniting with the latter at one place. It generally lacks the brown zineblende of the Francis. On Bunker Hill No. 12 level it has a strong shoot of good ore.

The 'N' fissure near the surface is a persistent vein between the Lower Cate and Republican faults, lying under and roughly parallel to the Jersey fissure. A notable feature is its crookedness and tendency to rapid changes of strike and dip. It was produced by a thrust that may have been five times as great as in the case of the Jersey. It starts at the surface in Upper Burke and, with depth, crosses the Buckeye and Tyler faults into Lower Revett quartzite. Two ore-shoots are discernible; they are probably related to the section where the vein passes the Tyler fault at a very acute angle. The Kemp fissure on Bunker Hill No. 10 level probably represents the vein under the Cate faults. It originally ended near the Sullivan fault. The production of the vein above the No. 9 level will probably reach 100,000 tons. Shorter and much less important fissures of the same system occur at various places in the mines.

The Sierra Nevada vein has the form of an anticline whose axis strikes S.45°W. and descends 85 ft. in 800 ft., until it reaches the Oakland fault, after which it pitches more steeply. The thrusting and arching of the rock over the fault opened spaces of lenticular shape in which the vein proper was deposited. Perhaps there was also some metasomatic replacement. The main ore-shoot occupied the nearly flat portion near the axis of the anticline, with some lenses probably 6 ft. thick. Much of the ore was oxidized and in 1887, according to Ransome, carried 47% lead and from 60 to 90 oz. silver per ton. The production of the mine is unknown. The vein is extremely crooked and is cut off on the northeast by the Cate faults.

The Caledonia vein is probably a portion of the Sierra Nevada vein. As faults place them in the fourth system, but there was probably renewed movement and mineralization in the Jersey stage. The Caledonia vein is extremely

crooked and is cut by many faults of small throw that do not seriously disturb its general position. There is always at least a little gouge, with small quartz lenses distributed along it, and more or less quartz in seams and pockets in the neighboring quartzite, often extending 10 to 20 ft. from the fissure proper. In a few places where it is parallel to the stratification, the gouge is very thin and the mineralization light. Galena seems to have been developed largely in distinct shoots, but tetrahedrite seems to have been much more thoroughly distributed along the vein, which may be an indication of two periods of mineralization. The metal salts have been largely leached from the vein near the surface and carried down to enrich the lower portion of the oxidized zone. Thus we find much limonite in the vein near the surface, but not much of silver or lead minerals and no visible copper mineral. In descending on the ore-

JERSEY VEIN IN BARNEY DRIFT.
(Photo by W. J. Elmendorf.)

shoot, lead carbonate and silver salts become apparent and even much native silver appears in places. Lower, oxidized copper minerals are added to these and small bunches of very rich ore are found. The copper comes from tetrahedrite. Some of this is said to assay as high as 3000 oz. silver per ton. The main ore-shoot, characterized by much galena ore of high grade, is about 400 ft. long by the crooks of the vein and its western limit goes down on a course S. 15° E. It is flanked by less definite shoots characterized by rich argentiferous tetrahedrite with little or no galena.

The Senator Stewart vein is a narrow zone of mineralized rock which is the fissure proper, generally only 6 in. to a foot thickness of quartz and galena; where the vein is 20 to 30 ft. thick it consists largely of brecciated quartzite cemented by galena, blende, and some quartz. It varies in dip from nearly flat to over 45°. The vein is cut by several vertical faults that are ore-bearing.

The Silver King and Crown Point mines developed a

series of veins of the Jersey type, of which the main Crown Point vein dipped 20° to 30° northeast and the ore was cut off by the New Era fault. The orebody is reported to have ranged from 1 to 20 ft. in thickness; first-class ore is said to have carried 65% lead and 80 oz. silver per ton.

In the block of Prichard slate that lies north of the Osburn and New Era faults from Deadwood gulch west, there is a group of east-west veins that are nearly vertical or dip southerly at high angles. They are mostly ribbon quartz, with pyrite, blende, and a little galena. They are unfortunate in their environment. The veins of the Canyon Creek group near Burke are of the Jersey type, except that they have northwesterly courses and very steep dips. It has been pretty well established that they cease to carry ore in commercial quantities after they reach the Prichard slate. The same may be true in the Wardner district—we are willing to concede that it is. I do not say that any of the known veins under discussion are the roots of any of the known Jersey type of veins south of the Osburn fault, but that they are members of the same system, those in the Prichard slate very low in lead content.

(To Be Continued.)

Record Sinking on the Rand

*The southeast shaft of the Government Gold Mining Areas (Modderfontein) Consolidated was sunk 233 ft. during March, which is certainly a record for the Rand and, it is believed, the world's record. Great credit attaches to Martin H. Coombe, the manager, and to Messrs. Lowson, Readhead, and Robar, the sinkers, for this remarkable achievement. The previous record was 213 ft. at the Modder Deep, beating that of the south shaft of Brakpan Mines in July 1907. These shafts are of three and seven compartments, respectively. During the quarter, 583 ft. were sunk at the State Mines, which is also a record; at any rate, it compares with 532 ft. at the Brakpan Mines. It is usually considered that record sinking can only be attained in the Kimberley slate, and it has been said that a monthly record depends largely on the date at which the Kimberley slate is entered, so that the greatest possible distance during the calendar period can be sunk in that formation. This was, however, not the case at the State Mines, less than 80 ft. being in the slate shales.

The shaft in which the calendar month's record has been made is of seven compartments, the excavations being 45 by 10 ft., equal to 450 cu. ft. area, or 37.5 tons per foot of shaft in the solid. The total tons tallied for the month as hoisted for the 233 ft. sunk were 8155, equal to 35 tons per foot, which comes very close to the estimate. The sinking was done through quartzites and slate shales, 155 ft. of quartzites and 78 ft. of shales being pierced during the month. It is noteworthy that only one-third of the distance was in the Kimberley shale; previous records have been almost entirely in that formation. The record was made from 1738 to 1971 ft. Natives do all the hand drilling and shoveling, 82 natives with a leading sinker and a white assistant forming the shift's sinking crew. Eight-hour shifts are worked seven days a week. The majority of the 'boys' drill double hand, using 7-lb. hammers, the end benches only having 'single-hand boys' at work on them. The shaft is laid out with its long axis on the dip, advantage being taken of the bedding planes, the great majority of the holes being inclined to the north against the strata.

Sinking with a skip, one of the main objects striven for is a flat bottom, an ideal bottom having a bench only at each end. The reason of this is the greater facility for loading the broken rock into the skips and getting each skip in its turn into the bottom at approximately the same level. It is obvious that if the 'benching' system were in use in a skip shaft with the engine running double and the skips landing at the bottom of different levels, innumerable difficulties would be encountered, such as tipping,

risk of kinking the rope, either running the skip away empty or taxing the boys unduly by shoveling the rock three or four feet higher into the skip; in fact, many unforeseen troubles would be encountered which would cause delay and probably accidents. Blasting takes place every 8 hours. From 40 to 45 holes completes a round for a shift and 'squares' the shaft. These holes are drilled from 3 ft. 6 in. to 5 ft. in depth. Four are drilled abreast for the length of the shaft. The side holes are given from a plumb-line hung from the bottom set. Gelatine used is $\frac{7}{8}$ in. diameter; 66 $\frac{2}{3}$ % used is of Cape Explosives Co. manufacture and 33 $\frac{1}{3}$ % of Modderfontein. Bickford Smith's '27 Special' fuse is used, and Edgar Allen & Co.'s green label $\frac{7}{8}$ -in. steel. There is no pump in the shaft below 600 ft., the water, 30 skips a shift, being handled with the sinking skips from 'rings' at various points.

Four timbermen are employed in each of the four shafts which are being sunk on the State Mines. Two men and six 'boys' form the crew at the bottom, one man and four 'boys' are on the hitches, bearers, and permanent guides, and one man and one 'boy' on the brattice. All timbermen work morning shift only, from 7 a.m. to 3 p.m., and only for urgent reasons is overtime allowed. After the sinking shift is in the bottom and hoisting has commenced, the two bottom crew men go down with their lines, stage planks, blocks, wedges, and helpers. Their first duty is to block the next to the bottom set of timbers, using the bottom set to carry their stage planks. They are not allowed to interfere with the skips once they have reached their place of work, until the sinker has finished cleaning up, has his drills down, and has started his 'boys' drilling. Then the engines are handed over to the timbermen, who take them to hang the next set. From the time the banksman shackles on the first pair of wall plates until the set is hung, filled in, tightened up, and temporarily blocked, and the timbermen are up to surface with their stage planks and 'boys', is an hour to an hour and a half. Timbermen are not allowed to deal with tight ground on the timber. The sinker is responsible and is compelled to take it down. Knowing this, he is careful with his line. If a set of permanent guides is required or a set of bearers to be taken down, as soon as the timbermen have hung their wall-plates and had their filling in, timber sent down, they hand the engine over to the other man, who goes on with that particular work. Fifty-seven skips, or 114 tons of rock, has been hoisted from the bottom, one set blocked, another hung and filled, four 30-ft. guides hung and bolted up, the shaft drilled over in the usual manner and blasted a quarter of an hour before the end of the shift. All hitches are cut, bearers placed, and timber dropped while the shift is at work in the bottom. The shafts carry six 8-in. and 4-in. penthouses, two, one above another, in each 'dummy' compartment. Running four skips in a 7-compartment shaft gives each end and the centre compartment clear. In these the penthouses are placed.

There are 132 cu. ft. of pitch pine in each set. The timbers are 7-ft. centres, 6 ft. 3 in. between; wall-plates and end pieces 9 by 9 in.; centre studdles over the joint, 10 by 7 in.; corner studdles, 8 by 8 in.; intermediate studdles, 10 by 4 in.; dividers, 9 by 7 in. The guides are 8 by 4 in. pitch pine, carried on channel brackets bolted to the dividers. One inch 'joggling' is used. Lagging, when any is used, is 12 by 12 in. pitch pine. Bearer sets are put in approximately every 12 ft., each bearer being made up of three pieces. Under the end pieces three 9 by 9 in., making a bearer 27 by 9 in.; under the dividers, three 9 by 7 in., making a bearer 27 by 7 in. Hitches are cut to a minimum of 4 in. in the solid surface. Wire plumb-lines are dropped once a month to check the timber and timbermen's lines. All the framing, guides, ladders, and rings are prepared for the four shafts by three men by hand. To date of writing, in this shaft, 64 sets of 7-ft. centre timber has been put in position in 61 consecutive days. This in itself constitutes a record, and is one that will be difficult to beat. Six hanging bolts on each side are required, three for each half-plate. 'Waverley' 1 $\frac{1}{4}$ -in. iron is used for the bolts.

*Advance proof from the *South African Mining Review*.

The wall-plates are in two halves, and are simply butt-jointed on a divider, no plating or bolting being used. The length of the two wall-plate halves is, respectively, 22 ft. 9½ in. and 20 ft. 8½ in., making a total length of 43 ft. 6 in. The dividers are 6 ft. 6 in., giving a shaft width over the timber of 8 feet.

Compartment sizes are as follows: The south or pump compartment is 8 ft. 6 in. by 6 ft. 6 inches in the clear. The other six compartments are each 6 ft. 6 in. by 5 ft. in the clear. The pump compartment is divided as follows: 2 ft. 8 in. ladderway, 3 ft. 6 in. for repairing cage, the 'runners' 4 in. and 4½ in., being bolted to the wall-plates, and 2 ft. 4 in. for pipe bearers and columns. The power cables are carried down in the space between the wall-plates and the repairing cage ends. All lights used in the shaft are carbide.

No fan or pipes are in use. A wooden chimney is built above the headgear the entire area of the pump compartment. A ⅞-in. brattice between the pump compartment dividers is carried down with the timber. This gives a natural draught of from 20,000 to 25,000 cu. ft. of air per minute passing over the shaft bottom. Ten minutes after blasting, the bottom is clear of smoke and fume.

The shaft is equipped with a modern steel headgear, 110 ft. from collar to platform, covering, of course, all the compartments. Two double-drum engines are in use, one a geared Robey 10½ by 33-in. cylinder, one a Fraser & Chalmers direct 22 by 48-in. cylinder. All the drums are 8 ft. diameter. The boilers are Babcock & Wilcox

majority of the producing mines can stope and hoist it. That is the difference in efficiency, though concentration of work has something to do with it. The highest tonnage broken per hole averaged over the month was 2.23, the gelatine consumption being 0.457 lb. The average number of natives per shift was 82.

Geology of Morocco

By MAXWELL BLAKE

The following notes concerning the geology of Morocco are of interest in view of the fact that present conditions in Morocco are likely soon to permit the inauguration of long-proposed railway projects which will result in the development of the country. These are not offered as of authoritative nature, but are generalizations gathered from persons of more or less experience whose observations have carried them into various parts of Morocco.

The general geological formations are of Paleozoic age, with outcrops appearing in the high ridges of the Atlas hinterland, and again in the vicinity of Casablanca and along the Mediterranean sea from Ceuta to Alhucemas. The wide areas between these outcrops are composed mostly of Tertiary sediments, between which are irregular layers identified as Mesozoic. Granites are abundant in the vicinity of Marrakesh, but northeast of that place they disappear or develop into melaphyres. Of igneous rocks of the Tertiary period, basalts and andesites have been reported. Copper, lead, antimony, manganese, and iron ores have been repeatedly discovered, while gold is said to exist in the regions of Sus. In the Tertiary sediments, large deposits of salt are obtainable, and the possibility of extracting potash salts is said to be favorable. In the outcroppings near Melilla, rock salt exists in association with large deposits of iron ore, reported to be of high quality. Deposits of gypsum are abundant in various places.

The opportunity for developing the mineral resources of the country is being eagerly awaited by persons who have secured denunciations. These denunciations signify that the mineral wealth within a radius of four miles of a certain point has been filed upon as the maximum which any individual may claim upon pre-emption. The only requirement for such a claim is an authorized survey by some qualified mining engineer acceptable to the legations of the nations concerned, and the filing of maps and reports of the discovery with the legation of the claimant.

Pending the promulgation of an international mining law, which has been under advisement and discussion by signatories to the act of Algieras, including the United States, no mineral rights have yet been definitely acquired, but allocation of them is to be recognized upon priority by international adjudication. Already four or five mining syndicates have been organized, but only the preliminary field work has so far been attempted. Owing to the experienced character of some of the persons who have interested themselves in the mineral exploitation of the country, present expectations do not appear to be speculative, especially as regards the existence of copper and iron.

In view of the accessible location of Morocco and its extensive coast line, both along the Atlantic and the Mediterranean, mineral wealth, in whatever part of the Empire it may be found, is not likely to encounter serious transport difficulties, especially should the building of initial railway enterprises be given materialization. In any event, present conditions appear to warrant serious inquiry on the part of responsible persons in the United States interested in mining developments.—*Daily Consular and Trade Reports.*

A RAILWAY is to be extended by the Sorocabana railway through the state of Sao Paulo, Brazil, from Salto Grande to the port of Tibirica. The government will supply the capital for the construction on a basis of \$16,000 per kilometre plus \$40,000 for the purchase of rolling stock. In addition to this, the company transfers to the government all its rights in the concession for the line from Sao Joao to Santos.

MAP OF SOUTH AFRICA.

Dutch-oven type. A 50-drill Fullerton compressor is also erected, but is not being used. The winding ropes are 1⅜ in. diameter. Sinking skips of 45 cu. ft. capacity are used. White and native 'change'-houses and workshops are of the most modern design and construction. Massive concrete collars have been put in, built up from the solid rock to from 5 to 6 ft. above the surface. The shaft is one of four of the same plan being sunk on the property, which probably constitutes a record for the world. The average sinking for March in the combined shafts was 694 ft., an average of 173 ft. 6 in. for each shaft. The total tonnage hoisted was 24,290.

The officials in direct touch with the shaft are mine captain, engineer, and foreman boilermaker. No shift-bosses or foremen timbermen are employed. The opinion is held that a shift-boss hinders and acts as a stumbling-block in the way of the man who is doing the work. The men are of the best type and work on the bonus system. The greater the footage the greater the pay and the cheaper the shaft per foot sunk. All men directly connected with the sinking join in the bonus list. Engineers work an 8-hr. shift, six to a shaft. The whole system works like clockwork and the result is efficiency of the highest order and good sinking. The State Mines is breaking, hoisting, and putting on the dump from the bottom of the shafts, rock at a cheaper price per ton than the great

Work of the Amparo Mining Company

This company, organized in 1902, with an authorized capital of 3,000,000 shares of \$1 each, which has since been decreased to 2,000,000, owns the San Juan y Santo Domingo, La Union, Breen Sucesco, Canada, Navidad, and other mines, covering an area of 300 pertenencias in Jalisco, Mexico. The company is owned by Americans and its main office is in Philadelphia. The mine office is at Etzatlan. The 50-stamp mill has 1050-lb. stamps, Krupp tube-mills, Wilfley tables, Dorr classifiers and thickeners, and Pachuca agitators. Details of operating expense are given in the tables. The failure of electric power and change to steam are responsible for some of the fluctuations.

During 1911 the mill ran 339,675 days, crushing 73,793 dry metric tons and producing in bullion, concentrate, and slag ₱1,425,650; from mine, ₱6702.64; shipping a total of ₱432,352.64.

Operating Expenses.		Per Ton.
Mining	₱356,430.43	₱5.22
Tramway and breaker	49,731.68	0.67
Milling	296,623.66	4.02
Marketing	28,102.76	0.38
General expenses	93,621.66	1.26
Totals	₱824,510.19	₱11.55

Value of Gold and Silver Produced.			
	Gold.	Silver.	Premiums.
Bullion	₱670,233.40	₱591,808.97
Concentrate, slag ..	180,692.87	102,965.71	₱2,660.16
Total	₱850,926.27	₱694,774.68	₱2,660.16

Ore sent to mill was produced as follows: Stopped, including ore produced by development, metric tons, 68,389; drawn from reserve dump at times ore from mine was not obtainable, due to accidents and failure of power, 6004; total, 74,393.

Engineer's estimate of ore in mine: Ore fully blocked out, 587,856 tons; partly developed, 118,779 tons; total, 706,635 tons.

Ore broken in reserve in mine: Reserve No. 1, 9838 tons; No. 2, 6295 tons; total, 16,133 tons; reserve in mill-bins, 600 tons.

Written off for depreciation of plant, ₱78,237.51.
Net profit for year, ₱406,750.13.
Dividends declared, 12% on \$2,000,000 capital.
The cost of fuel during the year amounted to ₱107,000 to supplement defective electric-power service. The ore fully blocked out is sufficient to run the mill eight years, crushing at the rate of 73,000 tons per year.

AMPARO MINING CO. STATEMENT OF COSTS (MEXICAN CURRENCY) FOR YEAR ENDED DECEMBER 31, 1911.

Sulphur, Pyrite, and Sulphuric Acid

In 1911 sulphur was produced in Louisiana, Utah, and Wyoming, according to W. C. Phalen of the U. S. Geological Survey. The principal producer was Louisiana, but in both Utah and Wyoming the output in 1911 was greater than during the preceding year. The production of sulphur in the United States in 1911 amounted to 265,664 long tons, valued at \$4,787,049, a substantial increase both in quantity and value compared with 1910. It is estimated that the production for 1911 is very close to the present rate of consumption in this country.

The production of pyrite in the United States in 1911 amounted to 299,904 long tons, valued at \$1,162,261, an increase of 58,292 long tons in quantity and of \$184,283 in value compared with 1910. These figures are the maximum ever recorded by the Geological Survey for the pyrite industry. Though low-grade sulphide ores of copper containing considerable quantities of pyrite and pyrrhotite and zinc sulphide concentrates have been used in recent years in the manufacture of sulphuric acid, the output of pyrite has shown a great increase during the last five years,

which has been a time of rapid development of the by-product sulphuric acid industry.

The output of sulphuric acid in 1911 amounted to 2,688,456 tons of 50° Baumé acid. Compared with the figures of the censuses for 1899 and 1904, this shows increases of great magnitude.

Six cars of high-grade ore will go out of Cobalt during the present year to Germany. The Crown Reserve company has renewed its contract with the Government of Saxony to supply a car of ore every second month, the cars to average 120,000 oz. of silver each. The Saxony smelters are operated by the Government for the benefit of the silver mines of the country, which are low-grade properties, and the Cobalt ore is required to raise the average to a point which will pay for treatment. The price received by the Crown Reserve for its ore in Saxony is a little better than the New York price of silver, the increase in price being sufficient to pay all the charges of shipping the ore the extra distance. Judging by the output of the mine last year, the Crown Reserve will deliver one-fifth of its total output to Germany, where the treatment of cobalt-bearing ores is highly developed.

Refractory Manganese-Silver Ores—II

By WILL H. COGHILL

(Continued from Page 754.)

The sample of the Jalisco ore tested, amounted to about one-third of the sample screened and could not be assayed because sampling would have involved crushing, but calculating from the table (IV) gave 16.99 oz. silver per ton and 8.16% manganese. Three products were made; the first looked like pure pyrolusite, the second contained small pieces of dioxide and quartz cemented together, which, if the reader will excuse a Joplin term, was 'chatty'; the third looked like nearly pure quartz. (The term quartz is used for simplicity and includes many light-colored silicates.) For want of better names, I will call these 'concentrate,' 'middling,' and 'tailing,' respectively. The analyses of these products bring to light some astonishing relations. The amount of silver found in the concentrate and tailing was about as expected, but the discovery of a middling containing practically the same amount of silver as the concentrate, and only about one-half as much dioxide, would make one feel that he has got some light on a problem which has perplexed so many. In fact, this explains at once why J. B. Empson reported of one of these ores that in a concentration test the tailing contained as much silver as the concentrate, and why E. M. Hamilton, after attempting to concentrate a refractory manganese-silver ore, stated that "the tailing assayed rather higher than the concentrate." Now since the tailing, as shown by Table VI, contains only 12.80 oz. silver and 71.1% (3.6 + 2.5 + 65) of the material in the middling is the same as that in the tailing, it is apparent that there must be some very rich grains in the middling. Thus the part that I had expected to throw away became the most interesting, and indicated that the amount of refractory silver varies, not as the amount of dioxide, but as the amount of cementing material and is therefore at the contact of the dioxide and quartz. Sixty hours grinding in cyanide, during which time the solution was changed twice, extracted 61% of the silver in the tailing (65). Under similar treatment the concentrate (63) yielded on 13.4% and the tailing from this test was given subsequent treatment as shown in Table VII.

TABLE VII				
JALISCO ORE				
0.5 A. T. Concentration (60-hour treatment in KCN):				
	No.	Mn. of Ag	% Total Ag	
Solution	66	2.28	13.4	
Residue	67	0.10	0.6	
(treated in H ₂ SO ₄)	68	0.68	4.0	
Residue	69	12.44	73.3	
(15 minutes treatment in dilute NH ₄ OH)	Error	1.50	8.7	
		17.00	100.0	

Here it seems that the silver is slightly soluble in sulphurous acid or ammonia, but subsequent tests proved that the amount is small and depends on the conditions. The 'error' may be due to the difficulty experienced in fluxing the residue containing the manganese salt, to the silver being put into such a state that some of it adhered to the jar, or more likely to a loss incurred by splitting the sample into four parts.

The most interesting feature of this table at the time the tests were made was the insolubility of the silver in ammonia. This was supposed to prove that cement silver was not present, but later it was found upon making a

test on silver leaf that the metal is practically insoluble in ammonia, though some texts say that it is soluble. During a two-days test on silver leaf in ammonia with frequent aeration, the silver finally decomposed, forming a dark-brown cloud and later a dark-brown flaky precipitate, but this change was too slow to be of consequence. There seemed to be reason to suspect the formation of cement silver (resulting from partial precipitation) in the sample as it was indicated that the acid had exerted at least some solvent effect on the silver. Now, if it had all been converted into a sulphate or sulphite and remained as such, it would have been soluble in the amount of solution used, but since the greater part of it remained with the residue, it seemed quite probable that it had been dissolved and then partly precipitated by the iron of the iron oxide, thus making cement or colloidal silver. All fears of cement silver being formed by the action of iron oxide upon the silver salt were dispelled by the test (70) following: A sample of the ore was treated with sulphurous acid to which was added a known amount of a solution of silver nitrate (the nitrate was of course converted at once into a sulphite or possibly a sulphate). The test was allowed to stand 15 minutes after the dioxide had all dissolved, thus exposing the silver salt to the reducing action of the iron, and was then filtered and washed. The assay of the residue showed that none of the silver was put into an insoluble state. (71) The insolubility of elemental silver in sulphurous acid was indicated by a test on silver leaf, the silver leaf remaining undissolved and without discoloration for two days in a stoppered bottle in the presence of that acid. It then took on a color similar to that of bornite and remained in this condition for several weeks. Therefore, it is seen that elemental silver is soluble in neither NH₄OH nor H₂SO₄; that a sulphate or sulphite is not formed, for if it were it would remain soluble and not be decomposed by the iron oxide, making cement silver.

TABLE VIII					
JALISCO ORE					
	No.	Mn. of Ag recovered	% Total Ag	Gm. of product assayed	Oz. Ag per ton of product assayed
0.2 A. T. concentrate treated in H ₂ SO ₄ :					
Solution	72
Sand	73	0.52	7.6	1.498	10.10
Slime	74	6.00	88.3	0.460	380.00
Error		0.28	4.1		
		6.80	100.0		

Before investigating Table VIII, which contains valuable information, a certain property of native manganese dioxide must be considered. When the dioxide is dissolved in sulphurous acid a light colored nearly gelatinous precipitate is formed which remains in suspension with great persistence. This consists probably of barium and calcium sulphates formed by the reaction of sulphuric acid in the sulphurous acid upon the oxides which exist as impurities in the dioxide. Now, in dissolving the dioxide in these ores the same sort of a precipitate forms, except it is colored a brick red due probably to the limonite in the ore.¹ (The solution, on account of conditions which

¹In fact, admixtures of manganese oxides and limonite are known to occur in all proportions, ranging from manganese limonites to manganese ores carrying only a trace of iron.

were not determined, may become red, due probably to ferric sulphite, and in turn be decolorized upon bottling.) This brick-red slimy material is called 'slime' in Table VIII. The heavier particles consisting mainly of silica are called 'sand.' These were separated very easily by decantation.

The amount of silver in the sand (73) corresponds closely to that in the tailing (65), but the concentration of silver in the slime (74) sufficient to give an assay of 380 oz. per ton gives a clue that is valuable, for the number of mills treating sand and slime separately runs up into the hundreds and in no case is there such a segregation of silver in either sand or slime. This indicates, then, that here we have to deal with silver in a form that has never been previously met in an ore.

After demonstrating that silver is released during the dissolution of the dioxide, forming such a light slimy product, it seemed best to make a series of tests to determine its chemical deportment, that is, to find whether it belongs to class x , y , z , or w .

Silver.	{ Artificial	{ x Elemental
		{ y Combined
	{ Native	{ z Elemental
		{ w Combined

If it is an artificial product, it would be expected to partake of the properties of any precipitate and form slime. If it is still in the native metallic state, remaining unchanged while dioxide dissolves, sliming is not to be expected. If in the native combined state, sliming is quite possible, for it is likely that the mineral stephanite (brittle silver) or any mineral as brittle as chalcopyrite, for instance, would segregate in the slime, though not to such an extent.

TABLE IX

JALISCO ORE

	No.	Me. Ag.	% Total Ag.
0.2 A. T. middling (treated in H_2SO_4 and washed):			
Solution	75	0.18	2.7
Residue	76	0.12	1.8
(treated 15 minutes in acetic acid, decant and wash)			
Residue	77	0.00	0.0
Mercury	78	5.75	86.0
(15 min. vigorous shaking with Hg)			

In Table IX (76) shows the insolubility of the silver in acetic acid, and in so doing, it certainly eliminates Ag_2O from y and probably w , though I am not informed in regard to its action, if such a native compound exists. The rest of the table deserves notoriety such as a criminal receives, therefore I will ask the reader not to place much emphasis on (77), which shows that the silver was refractory toward mercury. However, it led me to make some calcining tests, which are shown in Table X.

TABLE X

CALCINATION TEST, DIOXIDE TAILING, JALISCO ORE

(Calcined $\frac{1}{2}$ hr. after H_2SO_4 treatment, then amalgamated 2 hours.)

No.	Temp.	Per cent Extracted.
79	640	14.0
80	757	9.0
81	885	7.0

The so-called 'dioxide tailing' used in this table and tests following is the result of thoroughly cyaniding a hand-sorted sample containing about one-third dioxide. It assays 20.25 oz. silver. The amalgamating was done by grinding with mercury. An increased temperature of calcination is shown to have reduced the percentage of ex-

traction. After failing to amalgamate by the methods outlined in tables IX and X, what could one do but turn to wet reagents? The results were as follows:

(82) Oxalic acid and oxalic plus sulphuric—common solvents for MnO_2 —converted a part of the silver into an oxalate and sulphate, respectively. In several tests the dioxide was first dissolved in sulphurous acid and then given the above treatment. The results were all erratic and proved nothing except a slight solubility in all cases, the highest extraction amounting to 72.8 per cent.

(83) 'Hypo' was tried both in the presence of sulphurous acid and after the dioxide had been dissolved, but proved also a poor solvent, though as high as 50% of the silver was extracted in one case.

In a series of tests, in all of which the dioxide had been dissolved, a solution (84) of $KI + HgI_2$ with subsequent treatment in $NaCl$ extracted 47% of the silver; (85) agitating 15 minutes in 20% HCl cold chloridized 46.3%; (87) a 10% HNO_3 solution (cold) extracted 66.7% in 45 minutes; (86) fourteen hours agitation in 5% H_2SO_4 extracted 7.4%; while (88) a hot solution of the same strength extracted 75.4%; (89), a concentrated brine solution, failed absolutely.

I will not burden the reader with a further recital of tests which show the perversity of this mineral, though I have before me, tabulated, the results of 40 assays which were made by a student to determine the dissolving power (after the dioxide had been decomposed) of the following reagents which I will repeat in the order of decreasing dissolving efficiency: HNO_3 hot, HNO_3 cold, $KI + HgI_2$, oxalic + H_2SO_4 , oxalic, 'hypo,' H_2SO_4 , $NaCl$, NH_4OH . Suffice it to say that the best is a poor solvent. What, then, was my surprise to find, (90), that a 3% cyanide solution dissolved 89% in 15 minutes, and (91) 96.3% in 1 hour, a dissolving rate comparable with that of silver chloride in trough lixiviation. Of course, I was quite aware that cyanide was a good solvent, but such rapid action is not the ordinary rôle of KCN . Now, what about the criminal referred to in (77) which indicated that mercury was a solvent? This test was repeated and made (92) in the same manner as before, with the addition of an ammonia treatment which followed the acetic acid. The mercury extracted nearly all the silver. In short, it developed that a small part of one cubic centimetre of dilute acetic acid was sufficient to put the silver into such condition that an amalgamation was impossible. No visible films were formed on the mercury. Taking into account the relative amount of materials, it would seem that the silver, not the mercury, was to blame. Just to clear up the matter and show that mercury was a willing solvent, test numbers (93) and (94) were made during two and four hours, giving, respectively, 80.7% and 87.6% extraction. These amalgamation tests now harmonize perfectly with those made on the Arizona ore. The lesson, then, to be emphasized in connection with Table X is evident: do not try to amalgamate after calcining the acid-treated ore, though the temperature be kept low. There seems to be an incipient fusion of the silver or gangue, or both, which prevents amalgamation.

Ordinarily it would be possible to recapitulate after such a series of tests and to draw accurate conclusions, but in this case, if one conforms to the statements in books on chemistry and metallurgy, he must conceit some unheard of compound. However, after correcting an erroneous impression in regard to ammonia, everything except the peculiar conduct toward acetic acid and extreme solubility in cyanide points to x —elemental, artificial, or precipitated silver. Now, any millman would view with disgust the statement that precipitated silver is readily soluble in cyanide and cite good authority for his belief. Though I would not disagree with him in regard to silver precipitated from cyanide solutions, I believe that the rule is not of general application,² and submit Table XI. The

²Louis Janin, *Eng. & Min. Jour.*, Dec. 29, 1888, showed that cement silver is quite soluble in dilute standing cyanide solutions, but less soluble in a concentrated solution. He does not say how the cement silver was prepared.

amount of ore taken in each case was 0.2 A. T. The '25 mg. Ag added' was precipitated silver in the form of a very fine powder, precipitated from an ammoniacal solution with ammonium formate. It was added to the sample and given several hours grinding in a jar-mill previous to the preliminary treatment in sulphurous acid.

The table is intended to show the relative solubility of precipitated silver and the silver in the residue remaining after treating the ore in H_2SO_3 . Incidentally, it emphasizes a point already made: that of the greater efficiency of the 'extra solution' when compared with thiosulphate—compare (95) and (97). The same thing is noted in (96) and (98) where the precipitated silver is dissolved; (99) and (100) show how readily the precipitated silver and the silver in the residue is chloridized by cupric

TABLE XI				
DIOXIDE TAILING, JALISCO ORE (Preliminary treatment in H_2SO_3)				
No.	Mg. Ag Added	Kind of Solvent.	Hr. Agitated.	% Extracted.
95	..	Thiosulphate 3%	16	40.7
96	25	Thiosulphate 3%	16	45.0
97	..	Extra solution ('hypo' 3%, $CuSO_4$ 1%)	16	97.8
98	25	Extra solution ('hypo' 3%, $CuSO_4$ 1%)	16	80.0
99	..	$CuSO_4$ 3%, $NaCl$ 3%, then NH_4OH	8	76.8
100	25	$CuSO_4$ 3%, $NaCl$ 3%, then NH_4OH	8	89.0
101	..	KCN 1.5%	1	96.3
102	25	KCN 1.5%	5	85.0
103	..	Amalgamation	2	80.7
104	25	Amalgamation	2	90.0
105	..	$Fe_2(SO_4)_3$ 3%, H_2SO_4 0.5% cold	10	11.1
106	25	$Fe_2(SO_4)_3$ 3%, H_2SO_4 0.5% cold	10	46.3

chloride. The ready solubility of the silver in cyanide as shown by (101) has been referred to before and is put in this table so that it can be compared with (102) which shows that precipitated silver has about the same solu-

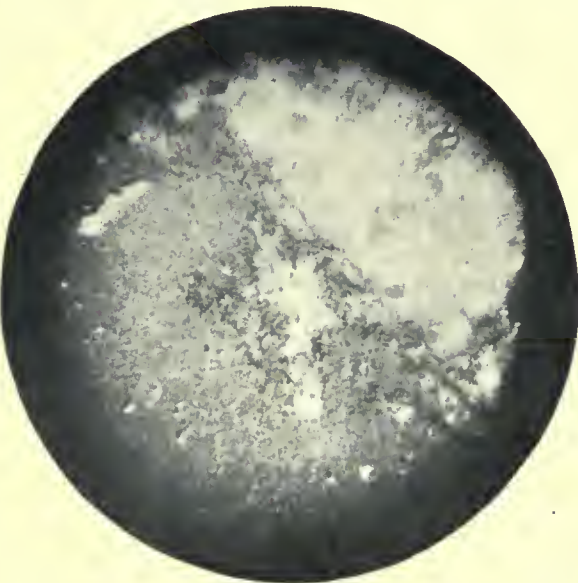

FIG. 1. CONTACT OF QUARTZ (TO THE RIGHT) WITH DIOXIDE OF MANGANESE (TO THE LEFT).

bility as the silver in the residue. The amalgamation tests in (103) and (104) compare favorably. In (105) and (106) there is a lack of the harmony that is not shown in the preceding tests. H. N. Stokes³ has tested the solubility of silver in ferric sulphate and finds that the reactions involved are reversible, silver being dissolved and in turn precipitated upon change in temperature. Consequently, I am inclined to ignore the tests with ferric sulphate and to conclude that since the silver in the residue dissolves in the other reagents at so nearly the same rate as does the 'Ag added', the silver in the sample belongs

to the group *x* and might well be called cement or precipitated silver.

In Table XII the subject is attacked from rather a different viewpoint. After considering the condition of the silver in the dioxide, it seemed desirable to learn in what kind of dioxide grains the silver occurs. The sample was screened and washed as explained in connection with Table V, and six products were made by hand sorting. The calculated assay value is 18.42 ounces.

TABLE XII					
JALISCO ORE (Classification by hand sorting.)					
No.	Gm.	% of Total	Oz. Ag per ton.	% of Total Ag.	
Concentrate	107	15.00	7.5	21.70	8.8
Middling	108	44.50	22.1	39.00	46.7
Tailing	109	135.00	67.1	9.60	35.0
Dioxide (botryoidal and stalactitic)	110	1.85	0.9	134.00	6.6
Dioxide (flaky or cleavable)	111	1.60	0.8	18.20	0.8
Iron oxide (red and yellow)	112	3.20	1.6	25.20	2.1
		201.15	100.0		100.0

The middling or 'chatty' grains (108) running high in silver corroborate the statements made in connection with (63) and (64) and the high silver in (110) and low silver in (111) show that the botryoidal and stalactitic pieces of dioxide give a higher assay in silver than does the very flaky and cleavable dioxide. Or, putting it another way, (108) and (110) show that the chatty and stalactitic grains are the richest. The iron oxide (112) assayed higher than was expected. It was not absolutely free from dioxide; this may account for it. In order to follow up this study of types of grains, a number of micro-sections were made; those of the types included in (108) and (110) receiving the most attention. The slides were all examined by an experienced petrographer and nothing of interest noted. Now the study of opaque minerals, such as the oxides of manganese, of course, involves the use of reflected, not transmitted, light. I felt certain that a 'chatty' piece should reveal something characteristic in the dioxide and near the contact with the quartz. I therefore tried reflected light, both natural and artificial, with and without a vertical illuminator. After several hours of such experimenting, I succeeded in getting focused on some dark brown spots in the steel-gray dioxide and near the quartz contact. I say spots instead of mineral grains, because they did not show a definite contact, but blended into the dioxide. The spots were found along the contact and reminded one of the way drift-wood may be strewn along a lake shore. After these things were found, their identification became much easier, they being most easily seen in a moderately bright reflected sunlight. Wishing to secure photographs, I visited the metallographers for the Illinois Steel Co., who spent about two days with me polishing sections and using their metallographer's outfit for magnifying and photographing. This work was a failure. L. H. Weld, who has made a specialty of photographing micro-sections, then came to my rescue. After several hours adjusting and waiting for a light of the proper intensity, a negative (113) was secured. It has been intensified to bring out the dark brown spots which photographed darker than the polished dioxide. Though the dioxide is actually the darker, it does not seem so in the picture, because of the minute flakes which reflect the light and give it the appearance of micaceous hematite. I cannot say positively that the picture shows an unidentified silver mineral, but believe that it does. It seemed to me that a procedure similar to the following should give proof. Remove the cover glass, dissolve the balsam on the upper surface with

³Economic Geology, Vol. I, 1906, p. 649.

alcohol, then submerge in sulphurous acid and let remain undisturbed until the MnO_2 dissolves. Take from the acid bath and inspect the residue under the microscope and place it in a cyanide bath. Silver would be readily dissolved and its disappearance when noted by means of the microscope would be positive proof of silver. This was tried, but was a failure, possibly on account of the residue of limonite which veiled the silver. However, I think that persistent efforts along this line would be successful. I studied one slide of the stalaetite dioxide (110), but found nothing similar to that noted above.

RESUME

1. A screen sizing test, Table I, showed a decided segregation of the silver in the smaller, therefore softer, grains.

2. Treating the cyanide tailing, Table II, in a Thoulet's solution showed a segregation of the silver in the heaviest grains.

3. About 60% of the silver in these ores (3), (44), (64), and (65) could not be dissolved in KCN.

4. Nitric failed absolutely (4) to dissolve the refractory silver. A silver mineral that could not be dissolved by either KCN or HNO_3 was probably unheard of until noted recently by E. M. Hamilton.

5. The silver can be chloridized (5) and (6) by HCl, which dissolves MnO_2 and possibly other oxides, thus indicating that the silver is in an oxide.

6. The silver can be chloridized (7) by sulphuric acid and salt, a common solvent for MnO_2 .

7. Sulphurous acid is a remarkably active solvent (8) and (9) for MnO_2 , but does not dissolve the silver.

8. After dissolving the dioxide in H_2SO_4 (10) and (11) the silver can be amalgamated or cyanided, though great care would be necessary to prevent undue consumption of cyanide by the soluble manganese salts resulting from the acid treatment. If carbonates are in the ore the acid treatment must be under pressure.

9. The gold (19) is amenable to cyanidation.

10. Many of the common solvents for silver, Table III, are effective only after the dioxide is dissolved.

11. In (24) the order of increasing efficiency of the thiosulphates was, calcium, sodium, potassium, and ammonium.

12. The Russell 'extra solution' (28) might prove that it has virtue where thiosulphating is practised, but the conduct of the NaCl (31) and (34) must be watched.

13. One pound of S as SO_2 (13) and (45) will dissolve about 1.3 lb. MnO_2 .

14. Manganous sulphate (54) does not aid in chloridizing roasting as do iron and copper sulphates.

15. The chloridizing roasting (52) of ores containing MnO_2 is possible and is an absolutely new field as far as published data are concerned, even $CaCl_2$ (58) being operative. Attention has been called to the fact that NaCl and KCl can be mixed in such proportions that they will melt at 135° below the melting point of pure salt. A chloridizing roasting test with this mixture might prove instructive.

16. Comparing (49) and (46) shows that flour has an effect during calcination worthy of investigation. A reduction in a Stetefeldt furnace fired by gas and a deficiency of oxygen might accomplish the same results and obviate the introduction of objectionable constituents.

17. Hand sorting, though ordinarily impossible, can be done with perfect ease, after a wash in dilute H_2SO_4 , thus removing the dioxide stain.

18. Table V shows that the silver is largely in the dioxide, and Tables VI and XII show positively that the amount of refractory silver does not vary as the amount of dioxide, as formerly supposed, but as the amount of dioxide in contact with quartz, that is, as the amount of chatty material. This condition makes wet concentration absolutely impossible.

19. I have shown in (70) and (71) that silver does not form a salt with the reagent when these ores are treated with H_2SO_4 .

20. Table VIII shows what I consider an unheard of condition of silver in the ore, namely: Upon dissolving the dioxide in H_2SO_4 the silver is held in suspension in the solution with the limonite and other slime-forming compounds.

21. Acetic acid (77) makes this residual silver refractory toward mercury, but an additional treatment in ammonia (92) removes the obstacle, and it can be easily amalgamated.

22. Table X shows that the residual silver cannot be amalgamated after calcination at a low temperature. Calcining for $\frac{1}{2}$ hour at 321° below the melting point of silver being sufficient to bring about this refractory condition.

23. Many reagents (82) to (89), inclusive, were poor solvents for the residual silver, and Table XI shows a striking similarity of cement silver to the silver in the residue resulting from treating the ore in H_2SO_4 . The avidity with which KCN (101) attacks it indicates a unique mode of occurrence of the silver.

24. Now, it has been shown in Tables VIII and XI that the silver in the residue resulting from treating the ore in H_2SO_4 conducts itself unlike the silver in any ore familiar to myself, at least, and in a way nearly identical to the porous precipitated silver with which it was compared; that in (70) and (71) silver does not form a salt with the reagent (H_2SO_4) used in the preliminary treatment; that a micro-section (113) shows dark brown splotches in the part of the dioxide in which it had been previously predicted (64); and (108) that there was a segregation of silver. Therefore it seems evident that the cement silver is the result of a silver mineral being decomposed contemporaneously with MnO_2 , this silver mineral being the dark brown splotches above mentioned. To give the composition of this mineral would be mere conjecture. Its association with such a highly oxidized compound would suggest the oxide; if an oxide, then why does it not dissolve in acetic or sulphurous acid?

25. The outlook for investors in mines of this type is not good. Cyaniding without preliminary treatment is absolutely impossible. In the way of preliminary treatments, the one by sulphurous acid must be considered, though it involves purchasing sulphur in amounts of about one pound for every pound of dioxide in the ore, then it would have to be burned, and the resulting fume could not be handled without enough escaping to raise a protest among the millmen. The presence of carbonates such as calcite would increase the consumption of sulphur. The expense of neutralizing after such a treatment preparatory to cyaniding would be considerable. The alternatives of amalgamation and thiosulphating remain. The relative merits of the processes could be determined only by further experiments. If there were a good demand for artificial MnO_2 , the market could be supplied by applying electrolytic precipitation to the manganese solutions. The production of a cheap by-product, brimstone, at the smelters would lend favor to the H_2SO_4 treatment. Chloridizing roasting, I understand, has been practised on ores of this type, but cost of fuel and silver losses militate against success. Chloridizing has been mentioned under 15.

26. I submit this problem to both geologist and metallurgist: to the geologist for him to identify this evasive silver mineral and account for the mode of occurrence; and to the metallurgist for him to map the bodies of refractory manganese silver ores so that investors may receive fair warning, and after giving such warning proceed with the investigation of methods of extraction.

LAKE SHIPS have been increased rapidly in size. Ten years ago a boat which could carry 5000 tons of coal and would take on a load in from ten to fifteen hours was a marvel of efficiency. Today a boat which occupies the same relative position in lake shipping, will carry 15,000 tons and will receive or discharge her cargo in a maximum of five hours.

BULGARIA produces a fair amount of minerals, the chief being copper and lead ores, of which 18,506 and 3419 tons, respectively, were produced in 1910.

The Common-Wealth Mine

By LLEWELLYN HUMPHREYS

*The Common-Wealth mine, which is now controlled by the Montana-Tonopah M. Co., is situated at Pearce, Cochise county, Arizona, in the Turquoise mining district, on a branch line of the Southern Pacific railway from Cochise to Gleason and connected by this branch with the El Paso & Southwestern at Courtland, this branch road having Douglas as its terminal point. The distance to Cochise on the main line of the Southern Pacific railroad from Pearce is 16 miles, and to the smelting town of Douglas on the El Paso & Southwestern is 43 miles.

The properties consist of 10 full mining claims, 600 by 1500 ft., seven of which are patented, and two mill-sites. There is also an additional millsite leased for a term of years, this latter approximating 20 acres in extent, making a total of about 230 acres. The ore was discovered in 1894 by some cowboys by the name of Pearce. In 1896 the property was sold for \$275,000, at which time development consisted of workings only 50 ft. deep. The purchasers proceeded with development, shipping their ore to El Paso and Pueblo. In 1896 a pan-amalgamation mill of 200 tons per day capacity was placed in operation, working continually until destroyed by fire in June 1900. The erection of an 80-stamp mill was commenced immediately on the site of the old one, this latter mill remaining continuously in operation until December 1904, when on account of a cave-in at the mine it was closed down indefinitely.

In January 1905 the accumulated tailing was leased to Messrs. Swatling and Smith, who had been superintendents of the mill and mine, respectively, since the purchase of the property. A year later the company leased them the mine, and it is stated that during their first year's operations they paid \$200,000 in royalties. These leasing operations continued until November 1909, at which time the lessees asked for a renewal of the contracts. This not being granted, Messrs. Swatling and Smith bought a controlling interest in the mine. After securing control and making a series of tests of the ore, it was decided to remodel and add to the equipment of the mill, when unfortunately the mill was again destroyed by fire through some defect in the electric wiring. The owners having exhausted their resources in buying control of the mine and adding new equipment to their mill, were not prepared to rebuild. During the period the property produced about \$10,000,000 and made several owners rich.

There are two distinct systems of fissures which have apparently been the primary cause of the ore deposition. These have a general trend of east and west, and dip to the south about 60° from the horizontal. There is a distance of about 175 ft. between the fissure systems at the main workings, but apparently they come together toward the west end. The andesite is brecciated along their course. This brecciated condition allows the silicification and mineralization of an immense area extending practically from one fissure to the other, but naturally with the heaviest mineral deposition immediately in and adjacent to the fissures.

The principal workings are on the south side of the enriched zone, on what is termed the South vein. The main ore-shoots have been worked along this fissure for a distance of 800 ft., and for a width of 70 ft. into the foot-wall. Numerous small faults, in the main part enriched, are present in the workings. They are, for the most part, parallel to a main fault crossing between shafts B and C. North of the main workings in the east end of the Silver Wave claim, and distant about 250 ft. from the hanging wall, is a very large outcrop of brecciated andesite which is over 70 ft. wide and highly silicified. This forms part of the surface showing on the north vein, contains small amounts of gold and silver, is traceable for

over 2500 ft. along its strike, and dips south about 65° from vertical. As depth is gained, a gradual converging of veins would occur, increasing the possibilities for a highly enriched area.

On the North vein no work from the surface has been attempted except a shaft 72 ft. deep on the foot-wall side, with a cross-cut run into the vein at that depth. Assays from this cross-cut gave returns of 40 cents in gold and \$1 in silver. The only place this vein has been explored at depth is from the No. 3 level of the No. 4 shaft. A cross-cut was run, cutting a 4-ft. fissure, along which a 60-ft. drift was run, but it is doubtful if this is the North vein proper, as the wall underlying it is a mineralized andesite. The assays from this drift show good improvement over the surface. The North vein has exceedingly good territory for exploration, with a probability of finding new orebodies.

At water-level (No. 7 level) of the mine, 363 ft. from the surface, the workings show the numerous seams and fissures as in the upper workings, so that it is reasonable to assume the water action will redeposit precious metals through cross-fissures in solution on the foot-wall side of the North vein, the South veins showing increased values in gold in proportion to silver on the No. 7 level. No. 10, or Brockman shaft, shows a 5-ft. vein lying south of the main fissurings and dipping 60° north. This vein intersects the main South about 20 ft. above No. 7 level.

Altogether, the geological conditions with the nature of the ore occurrences, strongly indicates that large areas will be found carrying payable ores above water-level, which have hitherto been unexplored, while below water-level additional large orebodies may be expected in a territory practically virgin, but under somewhat different conditions from those found above. The large width, richness, and persistence of the orebodies from the surface down, together with the character of the ore deposition, indicate that at depth an unaltered sulphide ore zone exists.

The mine has been developed by a series of shafts, and nine levels to a total depth of 451 ft. vertically, the principal work having been done above water-level, 363 ft. deep, the seventh level of the mine. The different levels have been extensively worked, and on account of the open manner of working in the past several large caves have resulted. The caved areas on the property have uncovered ores on the foot-wall side of old stopes that will increase the tonnage, the caves in no way proving detrimental to the system of mining it is intended to use.

In virgin ground the cost of mining and development is placed at \$1.75 per ton. When the workings are in proper shape it will be possible to mine a large quantity of the low-grade foot-wall ores at a cost not exceeding 75c. per ton. Fuel oil for power purposes is delivered f. o. b. mines at \$1.52½ per barrel.

ESTIMATED ORE RESERVES

Total ore resources reported August 10, 1911.	\$1,783,106.41
Additional ore resources reported March 25, 1912	
1912	186,624.52
Gross 314,545 tons	\$1,969,730.93
Total net profit, report August 10, 1911.....	868,292.16
Additional net profit, report March 25, 1912.	87,375.14
Total net profit.....	\$ 955,667.30

In the report of August 10, 1911, silver in ores and tailing was figured on the quotation of that time, 53c. per ounce. The advance in price of silver to present market quotations, 58¾c. per ounce, will increase the profits to be derived from ores \$124,000. In addition, during the month of March an offer was made by the Douglas smelting works of 60c. per ton for the remaining 80,000 tons of class 'A' tailing dump, which offer will doubtless be accepted. Allowing 10c. per ton for loading the tailing, the net additional revenue to be derived from this source will amount to \$12,800. Adding the above amounts to estimates previously given, the total net profits from all sources up to the present writing will amount to \$1,092,467.

*Abstract from a report made to the Montana-Tonopah Mining Company.

Iron Ore Reserves of Michigan

By C. K. LEITH

*In connection with the work of the State Board of Tax Commissioners, the mining properties of Michigan were appraised in 1911, under direction of J. R. Finlay.† The estimates of iron ore reserve were briefly summarized in the report of the Commission. Further details may now be given and are thus summarized.

A significant feature of the table given below is a comparison of fully developed bottom areas of ore by mines and districts. Only areas that give promise of continuity below have been tabulated. Exhausted or nearly exhausted mines are assigned bottom areas of zero. These figures are not strictly comparable throughout; in other words, each area does not have the same promise of con-

low-phosphorus ores of about 40% grade, which have been mined on both the Gogebic and the Marquette ranges. These lean ores are so abundant and grade so imperceptibly into iron formation that no estimate of their tonnage or area has been attempted. In considering the table, however, they should be taken into account as adding a considerable reserve, which would tend to make the total ascertained reserve nearly equal to the present total shipped from the region.

The probabilities of extension in every district but the Menominee are so strong that it is safe to estimate that for many years the ratio of reserve to total shipment will be maintained—in other words, that as much ore will be discovered yearly as is mined yearly. In fact, today the reserve probably bears a larger ratio to the total shipment than at any time in the past, and the possibilities of developing more ore are so great that ten years from now there will probably be greater reserve in portion to shipments than now. The increasing tendency of the larger interests to make sure of their ore supply for years in advance is leading to the development of increasingly large reserves in proportion to past shipment. Enough facts might be cited in relation to individual mines, explorations, and ranges to show that this forecast of the future is not based on vague surmise. Large extensions, both vertical and areal, are inevitable. Probably not more than 10% of the area of the upper Huronian slates of the Crystal Falls, Menominee, Iron River, and adjacent areas has been explored. Iron formation lenses are likely to be found almost anywhere in these slates. The heavy drift covering will make their discovery a slow and costly process.

The total known area of iron formation is 29,267 acres. In addition, there are fully 20,000 acres of magnetic belt in which exploration has scarcely more than begun. Probably half of this total acreage is iron formation of grade and character that will afford workable bodies of iron ore. The total area of iron ore in Michigan projected vertically to the surface is at present known to be at least 383 acres, or 1.31% of the area of total known iron formation. This area does not include many abandoned mines or worked-out portions of mines that are adjacent to present surfaces of ore. If these were taken into account, the total surface area of vertical projection of all orebodies present and past, would be considerably larger. Future discoveries are certain to increase this area still further. Therefore the av-

erage chance of finding ore in iron formation is larger by a considerable, but at present unknown, ratio than the percentage 1.31 given above. This figure does not necessarily indicate that only 1.31% of the 40-acre tracts carry ore, for the ore is so distributed that it includes or touches a much larger proportion of the tracts.

The conclusion therefore is that at no time in the past has the outlook for long life for Michigan iron ores been any better assured than it is now. There are few regions in which expenditure of money for large explorations can yield more certain results. The future size of the reserve will be in more or less direct ratio to the money expended in exploration. There is yet no indication of diminishing returns from exploration. In fact, increased knowledge of the geologic conditions is bringing more certain results for a given expenditure of money. The reserve will cease to grow only when difficulties of exploration or outside economic influences begin to limit the amount of exploration. This table shows the essential relative standing of the different ranges. The Marquette stands easily first in present tonnage and in future promise. The Iron River and the Gogebic are in nearly the same rank so far as

GEOLOGICAL SKETCH MAP OF THE MICHIGAN IRON REGION.

tinuity in depth. The notably large size of the areas of the Marquette ores is due partly to the low dip and pitch of the soft orebodies, which give them great horizontal and small vertical dimensions. Such orebodies signify future probable development, not below, but laterally, in the direction of pitch or dip.

Area of ore shown by drilling is not directly comparable to area of ore shown in present bottom-developed levels, for the reason that the drills may cut the ore at many levels, whereas the bottom-mine areas cut the ore at a single level. If the mined-out portions of the orebodies lying lateral to the levels estimated were projected to the surface, they would add an amount to the area of the present fully developed bottom levels which would make it more comparable with the area shown by drilling. The aggregate area of ore cut by drilling has been given only to afford a convenient comparison of the exploration in the different districts.

The table assigns no areas or tonnage to high-silica,

*From Advance Chapter 'Mineral Resources of the United States, 1911,' U. S. Geological Survey.

†Mining and Scientific Press, September 9, 16, 23, 1911.

present tonnage is concerned. The Menominee district has evidently seen its best days.

The present estimates of probable ore are limited by certain conventions, described elsewhere, which bring the total reserve to a figure below the total past shipment of iron ore from Michigan. There can be no reasonable doubt, however, that the reserve of iron ore, developed and probably available, approximates the total past shipment. This statement is true for all the ranges except the Menominee, and the shortage in the Menominee is more than offset by the great promise of the adjacent Crystal Falls and Iron River districts.

Most of the estimates received from the mines cover ore actually developed above the bottom levels. Some include, as probable ore, the extensions of partly developed levels. One company adds as probable ore an arbitrary unit of 2000 tons where the breast of the drift is in ore. Others have added as probable ore all the ground from 10 to 200 ft. below the bottom level, where the continuity of the deposits above and the geologic conditions indicate that the

to a few properties a little more ore than the mining company is willing to concede as a part of its probable reserve, but it is believed that these properties are extremely few; in fact, none are known. For most properties the probability is that the orebody is really much more extensive than has been estimated.

Ore cut by drilling has been treated in a still more varied fashion in the estimates received. Certain companies have merely turned in records of drill-holes without attempting to estimate the ore. Others have turned in a lump estimate—generally moderate. Others have given an estimate of the ore within a radius ranging from 25 to 100 ft. of each hole, and have made no attempt to connect holes. Others have drawn around each hole a circle having a radius of 50 to 100 ft., according to the thickness of the ore cut in the hole, and have then connected by straight lines the peripheries of the circles drawn around adjacent holes on the assumption that ore lies continuously between them. Others have treated the holes as means of showing cross-sections of a continuous orebody and have connected

the ore between sections, making no allowance for extensions beyond limiting holes. Still others have allowed extensions of 50 ft. beyond limiting holes. One company estimates its extensions beyond limiting holes to the point of a triangle distant one-third of the thickness of the ore shown in these limiting holes.

The possible variation in reasonable inference from drill-holes is clearly much greater than that from mine workings. It has been found desirable to use the same convention throughout in estimating from drill-holes, but the geologic conditions and the probabilities of connection of ore shown in different areas have been considered in determining a reasonable method of estimate for each property. Where the proximity of the holes to one another and the geologic conditions indicate a reasonable certainty of continuous ore between holes, the limiting holes have been connected by straight lines and the area between them has been rated as showing a thickness of ore equal to the average of that cut by adjoining holes. Allowance is made for irregular spacing of holes in estimating average thickness. Where the orebody has a steep dip or where holes cut it at an angle, due

allowance is also made. Where the holes are so scattered that it seems unsafe to connect the holes through so large an area, they have been connected in small groups and the area is estimated in the same fashion. As a rule, no allowance has been made for ore estimated by the companies to extend beyond limiting holes, and these exclusions should counterbalance possible errors made by including too large areas between holes. Where the holes are so distributed in linear fashion as to make it difficult to connect the corresponding areas, the method used by certain companies has generally been followed. This method gives the limiting holes a radius up to 75 ft., according to the thickness of the ore cut in the hole, and then connects by straight lines the peripheries of the circles of the limiting holes so circumscribed.

Of course, no possible method will bring this estimate of drilling to a single standard or degree of probability, for the geologic conditions shown by the different orebodies are extremely diverse. The method used, however, is so conservative that it can do no property substantial injustice, and it is practically certain that in most localities the quantity of ore present is far greater than that shown by the estimates.

Certain companies have made uniform deductions of 20% for mining loss and waste in their estimates and have reported only the available ore in their reserves. For certain localities, where the nature of or situation at the surface is adverse, still greater deductions have been made. Other companies, and these include the majority, made no

^a Low-phosphorus, high-silica mines not tabulated.

^b The phrase "vertical projection to surface" signifies that the area of dipping and pitching ore bodies is stated in terms of horizontal measurement at the surface—that is, that the structure has been flattened out in making computations.

^c Not rated according to tonnage of outputs.

ore is likely to have somewhat the same persistence below that it has above. Where drill-holes have shown ore that lies in advance of or below present workings and undoubtedly in the extension of the same deposit, the estimate of probable ore has been extended to include these holes.

It is obvious that if the estimates turned in were accepted as they stand, the reserves would not be treated in the same manner throughout, and that companies which used the more liberal methods of estimating would be at a disadvantage as compared with other companies. It has, therefore, been found desirable to formulate a convention to be applied, so far as seems reasonable, to all estimates. The convention is this: Estimates of developed ore are practically accepted as turned in. Estimates of probable ore are modified to include for each mine at least one full level below present workings, with an area equivalent to the average of the lowest fully developed levels. Also, partly developed levels are extended to the dimensions of the nearest fully developed levels. Where drill-holes show ore in advance or below and within reasonable distance of the workings, this ore is added. Where the orebody is actually exhausted or the geologic conditions show a strong probability of the exhaustion or narrowing of the orebody, this convention has been modified accordingly. In applying this convention to each property there have been taken into consideration the total shipment of the mine, the persistence of the orebody, the depth, the comparison of the areas of the lower levels with the average of the levels above, and the geologic conditions. It is possible that this method of estimate gives

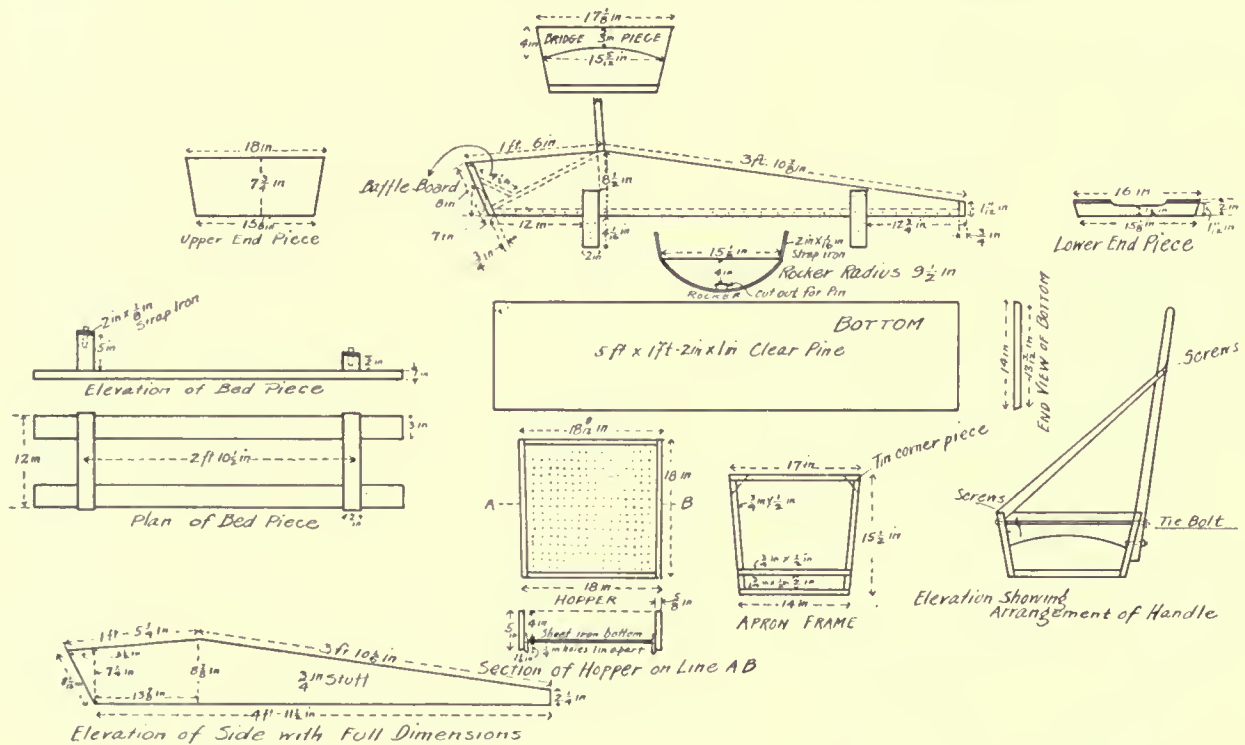

deduction for mining loss and rock. The variation in estimates due to differing treatment of these losses is not so great, especially between similar properties, as the difference in the treatment of these losses by different mining companies would indicate. It is probable that some of the company estimates make allowance for these losses even though it is not so stated. The estimates are made in so many ways and the variations in other features have been so great that in making deductions for mining loss and rock each of the companies has been considered individually. In general, the estimates made from drilling are reduced. The net effect is that the appraisers' estimates increase by 25% those made by the companies.

Rocker for Washing Gravel

By W. H. RADFORD

The following details represent a rocker which in the hands of a fairly careful man will give very clean results. It is a rocker that handles well and can be easily run.

possible to tell when the drill will go through a strong breast of ore into the mud. Workings are shallow and the expense is not heavy. The result is a very pretty speculation; if the ore holds out, money can be made rapidly, especially on such a market as the present one. But, in view of the uncertainty of the ore, it has always been the habit of the 'old-timer', in and about these camps, to have good reasons for selling out his mine just when it looked its best. Below Baxter Springs, Kansas, and across the line into the Quapaw reservation, there is a mining district which came into a good deal of notoriety owing to the promotion methods of some Kansas City schemers and some spectacular advertising. The land is owned by the wards of the Government—the Indians of the Quapaw tribe—and all operations are carried on by lessees. The ores of the district are found in somewhat of a blanket formation, at a depth of 90 to 180 ft. The rock is hard and crushing expensive. While there have been some good mills built, there has been a marked tendency to let the tenderfoot do the mining, the older operators confining their efforts to bringing a property, at a minimum ex-

DETAILED PLAN AND SECTIONS OF A ROCKER.

The only new feature about it is the baffle-break used at the upper end which throws any drippings from the upper holes in the hopper on to the apron. A piece of brussels carpet 13 1/2 in. is laid on the floor of the rocker to catch the fine specks of gold. This carpet, which extends for a distance of three feet from the upper end, is held in place by the crosspiece at the foot of the apron frame and by two strips, one on either side of the rocker. These strips are held down by wedges driven under small cleats nailed to the sides of the rocker. Very thin canvas or flour sacking should be used for the apron so that it can bag slightly.

Zinc and Lead Mining

In mining circles there is much interest in the market for lead and zinc. Lead-producing districts, such as Joplin, Webb City, Baxter Springs, and the various fields of Wisconsin are taking on a new lease of life and the continual prospecting that is necessary in all of these districts is being pushed with increased vigor. Under circumstances like the present, with lead and zinc at record prices, the mining industry as it is carried on in these regions makes a rather attractive gamble. In Oklahoma and in Missouri the ore deposits are irregular; it is im-

pense, up to the point where it shows a maximum of possibilities. Sixty per cent lead ore at \$58 per ton will mean a great deal of activity in options and properties in Missouri and Oklahoma, but the activity is not confined to those areas alone. The Consolidated Mining & Smelting Co., of Trail, British Columbia, is expending \$100,000 in betterments, including additions to its lead refinery. In New Jersey, the New Jersey Zinc Co. is reopening some mines abandoned twenty years ago.

Dividends

On Tuesday, June 4, the Bunker Hill & Sullivan M. & C. Co. paid dividend No. 177, of \$65,400. This makes the total amount of dividends paid \$13,519,350. The International Smelting & Refining Co. has declared a quarterly dividend of 2%, payable June 1. The Utah Copper Co. has declared its regular dividend of 75c. per share, and Nevada Consolidated declared 37 1/2c. per share. The Pittsburg Silver Peak has declared a dividend of 16c. per share, payable July 1. The Tonopah Extension has declared a dividend of 2 1/2c. per share, payable July 1.

Discussion

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Insertion of any contribution is determined by its probable interest to the readers of this journal.

Tonopah Milling

The Editor:

Sir—In glancing over the tenth annual report of the Tonopah Mining Co., by W. H. Blackburn, published in your issue of May 25, 1912, the mention of profitable improvements by cyaniding in place of concentrating leads to a reflection on the milling system practised for years. The use of stamps and concentrators with an endless chain of dewatering devices leads to the presumption of hard ore, as such a system has been the one favored by engineers for hard ore during the whole period of modern milling. At the Golden Star mine, Polaris, Yuma county, Arizona, years ago a system of rolls with coarse feed to tandem tube-mills was introduced and operated for years successfully. The ore was the hardest of quartz and the gold in the pure sulphides was as readily extracted as from the oxides. A saving of 95% was accomplished by cyanide process after thoroughly sliming the ore, agitating, and decanting the slime to a consistence proper for 40-lb. pressure filters. It seems that rolls should be preferred in newly designed mills because of the proved increased efficiency when the coarser feed is sent to tube-mills. This system eliminates the excess of water which must be a perpetual menace in cyaniding.

Drill-Holes and Patents

The Editor:

Sir—In your department 'Decisions Relating to Mining' I was interested to note that churn-drill holes had been allowed as improvements to apply on patent. If churn-drill holes so apply, is there any reason why diamond-drill work done for the purpose of determining the best place to sink a working shaft should not also apply? I had understood that diamond-drill work could be accepted for patent only when such work was in the nature of development rather than exploration. Can you tell me of an example of diamond-drill work that would be considered development and not exploration? If diamond-drill work can be applied on patent, it is of considerable importance to us, and I am seeking information on the subject rather than trying to emphasize a quibble in the use of words. But it seems to me that most mine work is exploration until ore is actually revealed thereby, when it at once becomes development work, and it appears rather strict to limit patent work to such conditions. Will you kindly tell me also where I can get the published decision on churn-drill holes referred to above and mentioned in your issue of May 18?

PAUL E. LODGE.

Bishop, California, May 23.

[The decision *ex parte*, C. K. McCornick and E. W. Bird, referred to in our issue of May 18, 1912, directly determined that diamond-drill holes were allowable as improvements to apply on patent, even when made for prospecting purposes. The First Assistant Secretary uses the following language: "It cannot be doubted that the drill-hole placed upon the Lake claim was for the purpose of prospecting it in order to secure data upon which the further development work could be based. This expenditure together with the other improvements to which the Commissioner made no objection, is more than sufficient." The decision, which is well worth reading, has not yet been published, but a typewritten copy thereof may be obtained for a nominal sum from the Surveyor General's Office at Reno, by referring to the title and date (March

14, 1912). It was on the basis of the above decision that Commissioner Proudfit held churn-drill holes to be acceptable in the case of the Globe, Globe Fraction, and other lodes.—EDITOR.]

The Prospector and the Mining Law

The Editor:

Sir—T. F. Van Wagenen's article, under the above heading, in the *Mining and Scientific Press* of May 18, discusses the occupation and interests of the prospector from an interesting point of view, and, as he says, "one somewhat different from that usually taken by the mining engineer or investor." While agreeing in his premises, as to the inducements necessary for prospecting, one may reasonably hesitate to agree with him in his apparent view that the occupation of the prospector is one that should be supported by continuing extralateral rights even if they lead to complications in operating mines. It is unquestionably true that the prospector depends, for his financial returns, on the speculative value of the prospects he opens. On turning over the files of the mining journals for the past five years, it will be seen that the trend of nearly all discussion has been toward the protection of the investor and toward discouraging him from purchasing prospects on their speculative value alone. After reading Mr. Van Wagenen's article, therefore, I feel confronted by the question whether the interests of the prospector or those of the investor are more to be considered. No doubt, as Mr. Van Wagenen says, the prospector is encouraged to risk his life on the desert and in the wilderness, by mining laws which permit him to initiate his work without capital. It is, however, also true that, no matter how favorable the mining law, he would not go prospecting if he did not hope to find an investor who would pay him cash for the speculative value of an undeveloped prospect.

It is not at all clear that the mining industry is substantially benefited by the opening of a maximum number of prospects and the sale of the speculative chance of their extralateral rights. In fact, I believe that in Mexico, where the mining industry thrives and where fewer prospects are formally opened, because of the expense involved, more care is exercised in selecting prospects for development. In all mineralized regions, as one travels, he sees dozens of properties on which money has been spent, often in considerable amounts, lying idle and exemplifying, as a rule, the profit of some prospector and the loss of some investor. The subject is too extensive and too involved to be settled off-hand, but it properly raises the question as to whether the prospector is the only one to be considered.

The statement that prospecting is much more extensive an occupation in the United States than in Mexico is also open to argument, for while the Mexican mining law theoretically places restrictions on all mining work and prospecting involves expense to those who do it in a formal way, there are, in Sonora at least, hundreds of native *gambucinos* operating without capital, who open prospects, work placers and abandoned mines, and recover very substantial quantities of precious metal. In short, they work with even more freedom than the prospector can in the United States, for the Government seems to ignore them entirely. The majority of these Mexican *gambucinos* work for revenue only; that is, for the value of the ore or metal they recover, but many of them offer to sell information of their prospects to American mining men and to Mexican capitalists, though their return for the sale of this information is usually small. The main difference between their work and that of the American prospector is that they only follow ore and, so far as I have observed, never drive cross-cut adits or sink shafts in barren ground. Without reopening the discussion of the merits and demerits of extralateral rights, I think it must be agreed that in the United States the sale of prospects is at present not nearly as active a business as it used to be, and we may expect, in future, to see the prospector conduct his work on a modified plan.

F. J. H. MERRILL.

Los Angeles, May 24.

Special Correspondence

JOHANNESBURG, TRANSVAAL

MARCH OUTPUT OF THE RAND.—PROSECUTION FOR FALSE RETURNS.—OUTPUT OF BASE MINERALS.

The returns issued by the Government Mining Engineer go to show that the gold output for March was really not as high as for the month of February, the Chamber of Mines output declaration for March being inflated by the inclusion of accumulated gold reserve. The following statement will show the position:

February		March	
Output, oz.	Value.	Output, oz.	Value.
Witwatersrand .735,230	£3,123,061	729,492	£3,098,686
Heidelberg 6,848	29,088	7,176	30,481
Klerksdorp 2,743	11,650	2,788	11,846
Ottoshoon 69	293	143	607
Pretoria	1	3
Barberton 9,198	39,072	7,345	31,202
Pilgrini's Rest... 12,767	54,234	13,974	59,358
Pietersburg 173	734	292	1,239
	767,028 £3,258,132	761,211 £3,233,422	

Sydney Penlerick, the ex-general manager of the East Rand Proprietary Mines, has been fined £100 for a breach of the Transvaal mining regulations in sending to the Government Mining Engineer false returns and figures regarding the gold output each month at various periods between April 1909 and August 1911. All the gold had been accounted for, but as previously pointed out, where the clean-ups were delayed to such an extent it was impossible to file correct returns, and it was proved that cyanide gold had been returned as mill gold to make the statements harmonize with the total gold produced. It was also proved that the gold was not always recovered during the same periods of time shown in the returns, and it was clear that there was no alternative but to institute proceedings in such a glaring case.

Good progress continues to be made in the output of base minerals, which during March, exclusive of diamonds, attained the value of £336,595. Owing to the English coal strike the export and bunkering trade of the Transvaal was lively, and a slight improvement was noticed in Natal, the total coal sold in South Africa during March reaching 680,988 tons, as against 605,034 tons in February. Instead, however, of prices improving they showed a decline of 1d. per ton, the average pit-top price in the Transvaal falling to 4s. 4d. per ton, and if the present tendency continues coal in the Transvaal will soon be as cheap as in any other mining country in the world. The value of the copper ore shipped from the Union of South Africa was during March £117,463, as against £119,954 in February, and the prospect of any marked increase in the amount of shipments south of the Zambesi are not encouraging. The output of tin continues to belie anticipations, for despite the discovery of the Waterburg fields in the Transvaal the output does not materially improve. The production of other miscellaneous base minerals and metals is unchanged. If diamonds are included, the monthly value of the mineral output of South Africa is well over £4,250,000, so that during the current year it is not at all unlikely that it will reach a total of £52,000,000.

Now that unskilled native labor has become more plentiful, it is evident that it is displacing a number of rock drills hitherto used for stoping, because in March the number of drills operating was again reduced, and only totaled 4689, against 4791 in January, despite the fact that during the last twelve months necessity has shown that drills can be substituted for native labor with satisfactory results. It is also satisfactory to find from last month's returns that the number of stamps dropped in the Transvaal and also in Lydenburg, Barberton, and Pietersburg districts along with the Rand continues to increase. Lydenburg is an outside district of some promise, where the gold output in the fu-

ture may be expected to show a steady increase. The total number of stamps dropped in the Transvaal in March is given as 10,236, as compared with 10,110 in February, but tube-mills running show a decrease of one. The outlook for the gold output of the Transvaal is still promising, but the increase can scarcely be expected to be as marked as during the past twelve months. The condition of the market has not lately conduced to the provision of more capital and several developing mines have had to close down on this account. Several of the amalgamated properties and new producers have, however, a reserve of idle plants which can be brought into use as labor and power conditions improve, so that on the Rand, at least, a steady increase in the output ought to be assured for some time.

TORONTO, CANADA

ORGANIZATION OF THE CANADIAN M. & E. CO.—DEVELOPMENT NOTES AT PORCUPINE.—OUTPUT AND DIVIDENDS AT COBALT.

A strong combination of Canadian and American capitalists has organized the Canadian Mining & Exploration Co., Ltd., with a nominal capital of \$5,000,000, half of it paid up. The board of directors contains a number of names notable in the financial world of both countries. The Canadians are: Sir Edmund Oster, H. S. Holt, Sir Edmund Walker, Sir Edward Clouston, Sir William Mackenzie, Duncan Coulson, D. Lorne McGibbon, W. Nesbitt, David Fasken, and P. J. McIntosh, and the United States is represented by Wm. E. Corey, E. C. Converse, P. A. Rockefeller, A. H. Wiggin, T. L. Chadbourne, Jr., J. R. De Lamar, Ambrose Monell, C. H. Sabin, R. M. Thompson, and C. L. Denison. The principal promoter of the enterprise is Ambrose Monell, the president, who receives no salary. The object of the company is the investigation and exploitation of American mineral resources, the idea being to secure the influence of men of large affairs, and to make sure at the outset of ample resources to obtain the best engineering talent to investigate opportunities for investment. The \$2,500,000 subscribed will be placed in high-class securities as an endowment fund and the income used for the maintenance of a staff and offices. The intention is to have offices at New York in charge of William W. Mein, and at Toronto in charge of A. D. Miles. It is proposed that apparently desirable opportunities will be examined and perhaps prospected, and the subscribers to the endowment fund are to have the privilege of participating proportionately in the promotion of subsidiary companies, in consideration of which they in the meantime waive interest on their contributions, the principal remaining unimpaired.

The country around Porcupine has been almost stripped of timber available for fuel, and many of the mines are beginning to use coal, among them being the McIntyre, which has ordered 2000 tons. This company on May 20, found a quartz vein 27 ft. wide on the 200-ft. level, near the centre of the west end of Pearl Lake. It is supposed to be the Hollinger lode. Another 4-ft. vein parallels it a few feet to the south. An 8-ft. quartz vein has also been found in the cross-cut on the 200-ft. level north from No. 4 shaft. The Pearl Lake property is to be re-opened, a syndicate of New York and Philadelphia capitalists having a controlling interest, liquidated the debts, amounting to about \$100,000, and provided a fund to carry on development work. M. J. Ramsay and J. E. Wright, of Philadelphia, have been elected to the board of directors, and R. W. Stevenson, an experienced mining engineer, has been placed in charge of the mine.

Directors of the La Rose mine from Montreal visited Cobalt and made a thorough inspection of the property on May 29. Their visit is supposed to foreshadow the investment of a portion of the accumulated surplus in some other mine, the Chambers Ferland being mentioned. The Trethewey is putting down a sixth shaft, near the mill, which will be sunk to 175 ft., at which depth it is intended to drive east along the line of the property adjoining the

Nipissing. The company has made a 10% distribution of profits. At the annual meeting of the Peterson Lake stockholders on May 27, an attempt was made to oust the directorate, which proved unsuccessful. The balance sheet showed \$44,022 cash in the treasury. The operating account showed a loss of \$1463. The leases have nearly all been cancelled, the only two leasing companies working on Peterson Lake ground being the Gould and the Seneca Superior. The plant of the Little Nipissing was bought for \$2400, and the Peterson Lake is now working the area formerly leased to it. The McKinley-Darragh produced in April 306,000 oz. of silver, and the management forecasts a total output for the first six months of the year of 1,500,000 oz. The two swamp veins, on which work was commenced April 1, yield ore running approximately 4000 oz. per ton, and carry occasional rich pockets of argentite. A 3% dividend plus a 7% bonus has been declared.

The Cobalt Townsite, which is nearly all owned in England and has lately made great strides, will take over the Cobalt Station Grounds mine, which comprises 19 acres of mining rights, under the land reserved for railroad purposes, and two town lots. This will bring the combined area of the two mines up to 57 acres. The Nova Scotia property was sold on May 2 to D. M. Steindler, of New York, a director and one of the largest creditors, for \$82,000. The total indebtedness of the company was \$245,000. The Coniagas has adopted an extensive plan for the development of the southern portion of the property, which has remained largely unexplored. A cross-cut is being run from the 225-ft. level toward the southern boundary, from which an adit will be driven toward an old disused shaft cut down for 60 ft., which will be reached by a raise. At the Nipissing good ore has been found in a raise from the intermediate level of vein 122, 60 ft. from the surface, where 12 ft. of a shoot has been developed along a drift. There is a 6-in. vein of 5000 oz. ore showing up for 9 ft. of height. A considerable tonnage of low-grade ore has been found on vein No. 73. At the W. S. M. K., formerly the Green Meehan, a vein found on the 200-ft. level has been proved for 125 ft. At first a mere stringer, it has widened to 9½ in. of high-grade, with good milling ore.

NEW YORK

COPPER MARKET LAGGING—TENNESSEE COPPER MERGER—CANADIAN MINING & EXPLORATION COMPANY.

The copper shares are still dull, in spite of much work by press agents. The investors are apparently studying the discrepancies that seem to exist between the reports from the mines and the refinery figures that are given out, and are asking "Where is all the blister copper that figures as mine output?" The market feature, both in New York and London, for some weeks past, has been a specialty that in its future depends almost wholly upon the elimination of copper as a conductor of electricity in telegraphy—the Marconi Wireless Telegraph issues. John Hays Hammond is about to attend the international wireless conference in London, and in the meantime is erecting two wireless telegraph towers on his estate in Connecticut to be used in experimental work in directing dirigible submarines in the waters of Long Island Sound. It seems odd that one of the world's famous mining engineers should act as a delegate to a conference to further a means of communication which will do away with one of the chief uses of copper when the system is fully perfected—which, by the way, seems to be a most distant day. Still, the fact remains that the American Telegraph & Telephone Co. is the owner of more copper metal than any other consumer in the world and one of the largest users of the metal.

Another passing phase of events just as odd is the talk of a proposed merger of the Tennessee Copper Co. with the American Agricultural Chemical Co. Farmers and smelters have always been considered as natural hereditary foes, and that it should be possible to merge anything which had to do with the one into anything which had to

do with the other, would seem most anomalous. The American Agricultural Chemical Co. has come forward as one of the successful handlers and dealers in chemical fertilizers, and the Tennessee Copper Co. has become one of the large producers of sulphuric acid. The story of a merger is denied, but nevertheless, chemistry, like politics, makes strange bedfellows when smelting plants that are looked upon as devastators of vegetation and fertilizer companies are spoken of as factors in possible consolidation.

American Smelters Securities are being pushed in the Paris market. The Bank of Paris and the Société Generale are offering the 6% cumulative shares on a basis of 95.

A concern with ambitious plans has recently been incorporated in the Dominion of Canada. The new venture is known as the Canadian Mining & Exploration Co., Ltd., and is made up officially of representatives on each side of the line in equal numbers. The promoters are all prominent either financially or in the mining field. The following are among the directors: Sir William Mackenzie, of Mackenzie & Mann, the great firm of Canadian railroad builders; Sir E. B. Oster, Sir Edmund Walker, Sir Edward Clouston, David Fasken, one of the most prominent attorneys in the Dominion, and who has taken a very large part in the development of Canadian mining industries; D. Lorne McGibbon, of the Nipissing and La Rose boards, and others of equal prominence. Among the American directors are Wm. E. Corey, former president of the United States Steel Corporation and now one of the inner circle in the copper combination headed by John D. Ryan; E. C. Converse, of the Bankers Trust Co. of New York, who is a member of the board of directors of the Dome Mines Co.; Percy A. Rockefeller, one of the most prominent financiers on the board; A. H. Wiggin, of the Chase National Bank of New York; Thomas L. Chadbourne, Jr., whose father was one of the determined and triumphant opponents of the Calumet & Hecla consolidation and who is one of the controlling forces in the Ahmeek; J. R. De Lamar and Ambrose Monell, both of whom are on the board of the Dome Mines. Mr. De Lamar being known all over the country where mining is being carried on, and Mr. Monell being head of the International Nickel Co. The concern is capitalized for \$5,000,000, half of which is paid in and is to be invested in high-class securities, the income from which is to be used to maintain an office and a staff of expert engineers who are to pass upon mining and other projects, and if available or worthy of development the stockholders of the company are to have the first privilege of supplying money for further work. The company's announcement is that the prospectors and deserving promoters are to be afforded a market for properties that will pass inspection by trained experts. The establishment of such an "endowment fund," as it is termed by the company's representative, appears at first sight to be tinged with a spirit of benevolence. The formation of a well equipped exploration company is a move in the right direction, and it is not to be disputed that the group of gentlemen mentioned will have at their call unlimited funds to develop anything that may be presented. Another phase of the situation not quite so encouraging is the possibility of the development of what is known as a one-man market. If everything which comes to New York must be presented to the one customer, and if turned down by it will receive a black mark that precludes its being taken elsewhere, so powerful a concern will be enabled to buy at its own price; and while the promoters will always have a market, it may not be a satisfactory one.

Probably of much greater importance to the mining industry in general is the encouraging aspect of affairs in Mexico. Speyer & Co., the international bankers of New York and London, have agreed, with the consent of the State Department at Washington, to lend to the present government of Mexico ten million dollars. It is expected that with this financial support the government of Madero will within a year be enabled to restore tranquility and then get its own financial affairs on a more substantial footing.

There has been a great deal of discussion recently as to the possible increase in dividends by the Nevada Con-

solidated and the Utah Copper Co. The rumors in regard to such increases were unfounded, as the regular dividends have just been declared. There is likely, however, to be an increase in the disbursements made by the Guggenheim Exploration Co., as this stock is expected to be placed on a 12% basis at a very early date. Neither Utah Copper nor Nevada Consolidated have ever been active traders. From the trend of events at the moment it is apparent that an effort is to be made to bring the Guggenheim Exploration Co. into greater popularity, and to this end it is pointed out that should either of the mining companies increase dividends, the Guggenheim Exploration Co. will be the largest sharer in such distribution. The Shannon Copper Co. is about to enter the dividend list, and it is expected that within 60 or 90 days its disbursement will begin.

The outstanding stock of the Inspiration Con. Copper Co. (\$14,452,160) has been admitted to trading privileges on the floor of the New York Stock Exchange. The stock will be quoted in dollars and cents. There is a good deal of talk to the effect that the Inspiration Con. Copper Co. is to absorb the new Keystone, which is a Lewisohn property, and J. Parke Channing has been in the Southwest watching some of the churn-drilling that is being done at the Keystone.

The Baltimore refinery of the A. S. & R. Co. is still having trouble with its 'hustlers', who handle copper ingots from refinery to steamer bottoms. Last month some 5,000.-000 lb. of copper was on the dock at Baltimore, and it is expected that exports will be delayed when the June figures come out, unless the present deadlock is broken.

SPOKANE, WASHINGTON

IDAHO MEETING OF SPOKANE SECTION OF AMERICAN INSTITUTE OF MINING ENGINEERS.

At the Wallace, Idaho, meeting of the Spokane local section, American Institute of Mining Engineers, May 11 to 13, about 100 members and guests were present. A special car was provided for those going from Spokane by the Oregon-Washington Railroad & Navigation Co., which arrived at Wallace on the evening of the 10th. The meeting opened at 10 a.m. May 11 at the Carnegie library, where an address of welcome by E. R. Denny, president of the Board of Trade, was followed by the formal turning of the keys over to the engineers by J. T. Taylor, Mayor of Wallace. F. A. Thomson, dean of the mining school of the Washington State College at Pullman, made a fitting response. R. S. McCaffrey, head of the department of mining and metallurgy of the Idaho State University, then called for the reading of papers. R. S. Handy, mill superintendent for the Bunker Hill & Sullivan M. & C. Co., at Kellogg, read a paper on the new unit of the Bunker Hill mill, which was illustrated by a flow-sheet. After discussion of this paper, O. B. Hofstrand, ore-dressing expert with the Federal M. & S. Co., at the Morning mill at Mullan, read a paper on the tube concentrator flotation process, with special reference to its installation and operation. As the process was first installed at the Morning mill and is practically new in ore-dressing practice, the discussion was extended and interesting. As a concluding paper, Mr. McCaffrey treated the subject of lead and zinc separation with special reference to conditions in the Coeur d'Alene district.

The afternoon was spent in an inspection of the Hercules mill, near Wallace, where the new Franz concentrating-table is being operated and experiments are being extended. There are one or two new features about this table which may prove valuable in concentration; one being the slots into which the metallic contents drop before reaching the lower edge of the table, and another being a device for classification which is employed on only a few of the newer tables and may yet be discarded. The Hercules M. Co. was the first to introduce ore-sorting from belt conveyors into the Coeur d'Alene district.

Next morning the party went by special train to the

Hecla mine at Burke, where the electric hoist is still doing duty as the most satisfactory hoist in the district. With a storage reserve, the hoist continues to operate for two hours after the current has been turned off the main line. Two hundred and fifty dividends are to the credit of this mine. From Burke the party went to Mullan, where the Morning mill with its tube concentrators engaged attention during the forenoon. These tubes are best described in Mr. Hofstrand's paper, which will soon be published. The first installation proved so satisfactory in saving lead and zinc which heretofore went out in the tailing, that the capacity of the tube plant is being greatly enlarged. The Federal M. & S. Co., both here and at its other ore-dressing plants, has introduced many innovations. Some of them in operation elsewhere are new to this district, but nearly all of them have come to stay. After luncheon a trip was made through the two-mile adit of the Morning mine, and the west face of the mine was inspected several hundred feet below, where 40 ft. of ore of all grades is exposed. The station in the adit is one of the largest in the world and contains the compressed-air plant for operating the hoist and ear loaders.

Returning to Wallace at evening, the party next morn-

KELLOGG PEAK, COEUR D'ALENE.

ing went to Kellogg, where headquarters was made at the Y. M. C. A., erected by the Bunker Hill & Sullivan M. & C. Co., a monument to better social conditions than formerly existed in this district. Although Mr. Hardy had faithfully described the Bunker Hill new mill, it is only by a visit to the mill itself that the automatic operation and devices which make possible such a high percentage of saving at so low a cost, can be understood. A miner who has worked for several years in the Bunker Hill & Sullivan mine, on being asked what the walls were, said "the walls are ore"; nor was he far wrong. This great property does not show the signs of exhaustion which might be expected from one which has been producing an enormous tonnage for a quarter of a century and which has paid \$12,000,000 in dividends. There are now large reserves of ore which may be mined at a profit with reasonable market prices for lead and silver, and new territory is being constantly explored.

At Kellogg the party separated, having spent a most profitable three days. Great credit was due the local committee and others for the profitable meeting and the facilities afforded for viewing the mines and mills of the district.

Last year the Coeur d'Alene district produced 30% of all the lead mined in the United States, and 8% of the silver, with large amounts of gold, copper, and zinc. The annual production of the state of Idaho, at the present rate, is about 120,000 short tons of lead, 2000 tons of zinc, 2,000,000 lb. of copper, 7,500,000 oz. of silver, and 60,000 oz. of gold. The rising price of the metals is stimulating prospecting and mining throughout the state.

BOSTON

COPPER MARKET ACTIVE.—WALKER'S ESTIMATE OF BUTTE.
—OLD DOMINION WINS SUIT AGAINST BIGELOW.

The movement of the copper metal market at present presages unabated activity through the summer months, and the possibility of 18 or 20-cent copper before the year is over. The statement for May will show a substantial reduction in stocks and bring out conclusively that the normal demand for the metal is well up with, if not ahead of, the supply. The continued rise in the price of the metal will enforce increased dividend payments in all the dividend-paying Boston coppers which have not yet raised their rates, and when these increases have been made and a few new coppers are also settled in the dividend column, the public will surely be in the market and the brokers will be prospering on commissions. The presidential campaign will not disturb the copper market. The final figures tell us that the production of copper has been stationary for the past two years, there being practically no change as between 1910 and 1911, but consumption has been steadily gaining ground, with no prospect of any reaction. Hence there arises a condition in the copper market similar to that which existed six years ago.

George L. Walker, editor of the *Weekly Copper Letter*, here, has been visiting Butte recently, where he went to look into the properties of East Butte, Butte & Superior, Butte Central, and other independents, from a market standpoint. Mr. Walker estimates the gross value of Butte's production to date as \$1,160,000,000, saying that only a few entire states in the Union have produced more mineral wealth than the Butte district alone. He quotes those having a comprehensive understanding of the district as saying that it will be a large producer of copper 100 and perhaps 200 years hence. He writes that prominent mining men in Butte declare that the Butte & Superior company has opened the largest known deposit of high-grade zinc ore, its orebodies being so large as to immediately force Butte into prominence as a zinc producer.

The United States Supreme Court, on Monday last, handed down a decision in behalf of the Old Dominion Copper Co., of New Jersey, against Albert S. Bigelow, of Boston, for \$2,200,000, plus interest at 6% for two years, making the total \$2,464,000. This terminates litigation of ten years standing and probably constitutes a record award as made by the court of last resort against an individual. I have already outlined the history of this extraordinary case. Mr. Bigelow, who is a member of one of the wealthiest 'Back Bay' families, had deposited with the New England Trust Co., as trustee, securities sufficient to settle the judgment against him for this amount which had been secured in the Massachusetts courts. The securities in trust now become the property of the holders of the trust receipts of the Old Dominion Co. of New Jersey. These trust receipts were created on account of this case and have been traded in fitfully from time to time. They have a par value of \$10, but have been traded in at all prices, from a dollar or so up to \$9 on Monday, the day the decision was handed down. The first sale Monday on the Curb of these receipts was made at 3½. The next sale was 9. A possible value of \$14 per share for the receipts is estimated. Richard Olney, Alton B. Parker, C. E. Littlefield, J. C. Spooner, and Louis E. Brandeis, of this city, were legal lights in the case. It is estimated that Mr. Brandeis, who is on the winning side, will receive a fee of \$220,000 for his work. It is believed in Boston that Mr. Bigelow has put down a fairly soft pillow to fall upon by 'hedging,' having, it is said, been persistently accumulating trust receipts for the past two or three months in anticipation of an adverse verdict. Mr. Bigelow was associated with the late Leonard Lewisohn in forming the Old Dominion Copper Co., and it was discovered that they, as promoters, had appropriated considerable secret profits. When the discovery was made, Old Dominion stockholders started

a movement against them both for restitution. Suits were instituted in New York against Lewisohn and in Massachusetts against Bigelow, the cases otherwise being identical. Lewisohn's estate won the suit, though Bigelow lost. Mr. Bigelow, who is advanced in years, retired from the copper field when the Calumet & Hecla company purchased of him his interest in Tamarack, Osecola, Ahmeek, Laurium, Seneca, and Isle Royale for \$8,284,375, three years ago.

SALT LAKE CITY, UTAH

ZINC IN PARK CITY MINES.—BAG-HOUSE AT UNITED STATES SMELTING PLANT.

The strength of zinc in the metal markets is giving an impetus to Utah mines in which zinc is a by-product, where in many instances it was previously a detriment. The greater part of the Utah production of zinc comes from the Park City district, where Daly-Judge and Daly West are the principal shippers of zinc ore, particularly the former. Daly-Judge stopped shipping zinc middling last October, and at the first of the year had 1136 tons piled up awaiting more favorable conditions. Since that time, however, it has resumed shipments, and the zinc middling is now contributing largely to the revenues. The North Tintic district, where the Scranton is the principal shipper, is also looking up for similar reasons, and the holders of property in the new Santaquin district, where zinc occurs largely under conditions similar to those at Park City, are greatly encouraged. The United States S. R. & M. Co., which is using the Huff electrostatic process at its Midvale plant, is engaged in a more active campaign for the purchase of ores containing zinc. In this connection it is interesting to look back a decade to contrast the value of metals and metallurgical methods. At that time the old Anchor mine, which is now a part of the Daly-Judge, had been practically given up by its owners, so far as hope of immediately profitable operations was concerned, because of the large proportion of zinc in the ores. The Daly-Judge, while it includes a vastly increased area and has opened other orebodies, has nevertheless reaped large profits from the Anchor zinc ores, which were previously a serious detriment.

The strike at the American S. & R. Co.'s Murray plant has apparently been broken, and lead ores are being received there the same as ever.

Utah Copper is steadily approaching its maximum production. The Magna and Arthur mills will be in shape next month to handle 20,000 tons of ore per day, and with adequate transportation facilities there will be nothing to prevent maintaining that production, which will bring the annual output of copper close to 150,000,000 lb. One day recently the output from the mine was 24,000 tons, a feat so enormous that its magnitude is not realized at first blush. The work on the Panama canal affords the only comparison.

Frederick Lyon, assistant managing director of the United States company, is authority for the statement that the company has solved the fume problem in its copper smelters as well as in its lead plants. Since the installation of the present bag-house system at the Midvale plant of the United States company, the trouble with farmers has died out. The company is operating its lead plant only, under order of the federal court, but the success of the bag-house at the Kennett copper smelter may presage the renewal of the treatment of copper ores at the Midvale plant.

The most extensive operations in recent years in the old district of Alta are in prospect, the newly organized Michigan-Utah Consolidated company being the active factor. The company includes the Utah Mines Coalition, City Rocks, and other properties, and is well financed. One of its plans is to utilize the old Continental-Alta tramway to a connection with a branch of the Rio Grande railroad in order to maintain shipments all winter. The camp is usually snowbound during the winter months, but the overhead tram will overcome this difficulty.

General Mining News

ALASKA

FAIRBANKS

The first two clean-ups from the winter dumps on the Bigelow claim on the left limit of Goldstream netted \$51,000. Water is available for only one string of sluice-boxes, but it is estimated that one-third of one dump has been washed already and the operators hope to have the two dumps cleaned up within a month.

JUNEAU

The report of the Alaska United G. M. Co. for April 1912 states that 18,144 tons of ore was crushed from the Ready Bullion claim, and 19,320 tons from the 709 Foot Claim. From the two mills 821 tons of concentrate was saved, with an estimated value of \$40,400. The estimated gross value of the free gold was \$45,750. The value of the total production was \$86,149, with a realizable value of \$85,288. The estimated net profit was \$26,431. Development to the extent of 607 ft. was carried on, and the stock of broken ore increased 4914 tons.

The report of the Alaska Mexican G. M. Co. for April 1912 gives the amount crushed for the month at 19,152 tons, with 419 tons of concentrate saved. The estimated gross value of the concentrate was \$32,550, and of the free gold \$25,586. The estimated realizable value of the monthly production amounted to \$57,635, with an estimated net profit of \$17,525. Development to the extent of 176 ft. was carried on and the stock of broken ore increased 16,956 tons.

The new Nugget Creek power-plant of the Alaska Treadwell company is to be completed this summer, and a large force of men is now at work.

ARIZONA

COCHISE COUNTY

The steel framework for the new flue-dust chamber at the Calumet & Arizona smelter is about half in place, and will be finished in a few weeks. Additional time will be required for the riveting.

The site for the new Shattuck smelter has been selected south of the Calumet & Arizona property. Plans are being prepared for this new reduction plant, which will have a daily capacity of 400 tons. Arthur Houle, of Douglas, will have charge of the smelter construction work.

GILA COUNTY

(Special Correspondence.)—Over 400 men are employed at the Inspiration Con. mines, and the force is being increased. Three development shafts are being sunk to greater depth, and ore from development work is being hoisted through another. The grading is being done on the site of the two concrete, 3-compartment working shafts which will be sunk 50 ft. apart near Inspiration. Ore from the Live Oak mine will be conveyed by underground haulage through the Keystone mine and hoisted through one of these shafts. Grading has not yet been started for the 7500-ton concentrator, as some details remain to be settled. The preliminary surveys for the railroad to the mine and to the concentrator site have been finished, and the dam across Pinal creek will be finished in a few days. W. C. Browning, formerly chief engineer at the Inspiration mine, has been made assistant superintendent and E. G. Deane is now chief engineer. The firm of Repath and McGregor, consulting construction engineers, has charge of all construction work. Associated with them are F. J. Brule, H. J. Wallace, and W. C. Holman, at the head of a corps of 14 engineers.

At the Miami mine diamond-drill hole No. 1 is 125 ft. below the 570-ft. level and has shown ore of commercial grade for the entire distance, which may be taken as indicating that the ore deposit extends to a greater depth than has ever been estimated, all previous estimates having allowed only 50 ft. of ore below this level. The tailing elevator is finished and working satisfactorily. All

tailing is now elevated 60 ft. and conveyed by a launder to the gulch, east of the mill, where it is impounded. The total number of men employed about the mine and mill is about 900.

The Copper Hill shaft of the Arizona Commercial company has been refimbered to the fourth level, and a drift is being run on that level to connect with a drift from the Gray shaft of the United Globe mine of the Old Dominion company. At the Copper Reef mine, 15 miles south of San Carlos, the face of the main cross-cut is being advanced, and is now in over 1000 ft. The drift from this adit on the California vein is in 60 ft., and its full width in vein material consists of red hematite and clay gouge. Charles Saxman is superintendent and 11 men are employed.

Globe, May 30.

MOHAVE COUNTY

The Frisco Mines & Power Co. is shipping regularly about \$15,000 in bullion from the mill each month. The ore is broken in the stopes by a caving system, and only six or seven miners are required to keep up the supply for the mill.

PINAL COUNTY

The American Smelting & Refining Co. has made its initial shipment of blister copper from the Hayden plant. Three cars were sent out consigned to the Perth Amboy refinery in New Jersey.

SANTA CRUZ COUNTY

The Sunnyside and Volcano groups of mines in the Patagonia mountains are reported to have been bonded by L. D. Ricketts, of the Greene-Cananea company. This property is within a few miles of the R. R. mine recently purchased by N. L. Amster, of the Shannon. It is also reported that the Calumet & Arizona company has acquired under bond the Chief group of mines in the same district. The Shattuck company of Bisbee also holds options on a large acreage of mining claims near Patagonia. Mr. Amster is prospecting about 30 claims by driving an adit several hundred feet in length. An orebody 47 ft. in width has been cut, and drifts are being driven to develop the ore.

CALIFORNIA

ELDORADO COUNTY

(Special Correspondence.)—H. Summertfield, of San Francisco, and Oliver Roberts of Alamos, Sonora, Mexico, have bought the Big Chunk and Tropical placer mines in the Kelsey district from the Murphy estate, and a company will be formed to begin work as soon as Mr. Roberts completes the examination of the properties. Placerville, June 1.

INYO COUNTY

The old Cerro Gordo property of the Owens River valley has been purchased by F. J. Hagenbarth, L. D. Gordon, and R. J. Shields, Utah mining men. The Cerro Gordo was one of the earliest mines worked in the Southwest. First operated by the Mexicans and then by Haggin & Hearst, it has a recorded production of \$20,000,000, the ore being a lead carbonate carrying an ounce of silver to the unit of lead. In late years the mine has had a succession of owners, and the last deal came about through the agency of bankruptcy proceedings and the foreclosure of bonds which the Four Metals company, recently owning it, issued to secure funds. The mine is developed by both adits and shafts to a depth of 1150 ft., and a great amount of zinc carbonate ore is blocked and left in the stopes from former operations. The equipment of the mine is modern, and the underground workings are reported to be in good shape. An aerial tramway connects the mine with the Southern Pacific tracks at Keller, and the present owners hope to ship 1000 tons of ore per day, with a zinc content of 35 to 42%, to Oklahoma.

PLUMAS COUNTY

(Special Correspondence.)—The Lawrence and Hudson placer claims, west of Greenville, have been taken under bond by the Altona syndicate, composed of Seattle and

Alaska people. The property, comprising about 800 acres, will be tested by shafts and drills. The same company has commenced sinking at the Altona quartz mine. A gasoline hoist is in place, and other equipment provided for. J. M. Wiswald is manager for the company. The Anti-Débris Commission has filed complaints against the Neoscene Hydraulic Mining Co., operating at Seales. The company has asked for permission to continue work until a clean-up can be made. The Crescent Hills company is rapidly completing its new cyanide plant, which is intended to treat tailings from the Crescent Hills and Green Mountain mines.

Greenville, June 1.

SACRAMENTO COUNTY

The Embaugh Mining Co. has reported the discovery of a rich gravel deposit, yielding \$20 per pan. The mine is at Prairie City, one of the oldest placer districts in the state, and all of the land in that vicinity had been thoroughly prospected, yet Sacramento capitalists who compose the Embaugh company have spent considerable money in developing their property.

SHASTA COUNTY

(Special Correspondence.)—There is renewed interest in the gravel deposits lying west of Redding. The Union Mining & Power Co. has planned to employ a force of 25 men for placer operations on Clear creek. Several small operators are active in the Igo, Muletown, and Shasta districts. The Santa Rosa National Bank has filed a suit claiming the Brush tract, immediately west of Redding. The Hazel G. M. Co., near French Guleh, is sinking the Gladstone shaft an additional 250 ft. to a total depth of 1150 ft. below the adit-level. This adit is 3000 ft. long and taps the vein about 1000 ft. below the outcrop. In the mill 30 stamps are at work, and the average monthly output approximates \$30,000, the 1911 yield aggregating \$362,000. The company has disbursed \$810,000 in dividends. I. O. Jillison is managing director and E. L. Young superintendent of this mine, which employs 120 men. The Milkmaid M. Co. is developing a 2-ft. shoot of ore averaging about \$20 per ton, in a drift 100 ft. from the mouth of the adit. H. F. Musser, superintendent of this property, has developed 200 ft. of this orebody in the roof of the drift. The Noble Electric Steel Co. is enlarging the capacity of its electric iron smelter at Heroult.

Redding, May 28.

A company has been organized which will purchase the railroad from Anderson to Bella Vista, and will then extend this railroad to the Afterthought mine and smelter at Ingot, subject to the approval of the State Railway Commission. No doubt the railroad will be extended in the future into the timber and agricultural lands northeast of Ingot, but at present the main idea of the company is to improve the transportation facilities to the Afterthought mine.

The Victor Power & Mining Co. has filed suit against the Midas G. M. Co. in the Superior Court at Redding. The Victor company owns a small mining claim, the Bonanza, adjoining the Midas ground, and alleges that the Midas company is taking ore from the Victor property in the workings on the 1200-ft. level. A restraining order is asked for enjoining the Midas from mining in the disputed territory until a survey under the direction of the court determines the rights of the two companies. The Victor company does not sue for a specific sum in damages, but asks the court to determine the amount. At the Midas 30 stamps have been dropping steadily this spring and fair profits have been claimed.

SIERRA COUNTY

Many mines in the Alleghany district will resume operations this month. Development is under way at the Rainbow, the El Dorado, and Oseola. The Sixteen to One is planning to place new machinery and deepen the shaft, and a new shaft will be sunk on the Lincoln-Roosevelt vein. In the Independence a drift is being driven north from the bottom of the 350-ft. shaft. The big adit on the Fruitvale is 650 ft. long, and a raise is being made on the vein, which is 12 ft. wide. The Lookout has started

an adit after an idleness on the property of fifteen months, and work at the Kenselbach and Red Ledge will be resumed in a few weeks. On the Hardy Kate property an air-compressor, driven by electric power, is being placed, for the purpose of driving a shaft on the northern extension of the Gold King.

A clean-up at the Bear Creek mine, a few miles above Alleghany, resulted in a yield of \$157 per ton. The ore came from a stope in a drift about 150 ft. from the surface, where the vein is 3 ft. wide. The mine is worked by John Andrews.

TRINITY COUNTY

The Trinity Gold Mining & Reduction Co. has reported a production of \$207,831 from the Headlight mine for 1911. The expenses of the company were \$141,566, leaving a profit of \$66,265. Additions to the equipment have been made and an increased output for 1912 is expected. The company claims to have a large amount of \$5 ore which can be mined by open-cut methods.

COLORADO

CLEAR CREEK COUNTY

(Special Correspondence.)—At the Kelly adit property on Democrat mountain, work has been resumed. As soon as the workings have been cleaned out, the compressor plant will be brought into commission. The 50-ton concentrating plant will be started during the next two weeks. F. Bromley is manager.

Georgetown, May 31.

OURAY COUNTY

The Camp Bird mill has resumed operations after a shut-down of several weeks. The new shaft is completed and a sufficient supply of ore for 30 stamps hoisted daily. Development has shown a large body of sulphide ore in the territory which is tributary to the new shaft.

TELLER COUNTY (CRIPPLE CREEK)

The Trilby mine on Bull hill, operated by lessees, is producing about 1000 tons per month from the 1100-ft. level. The properties of the Ophir M. & M. Co., together with machinery thereon, have been advertised for sale on June 25 by the sheriff, under decree of sale from the District Court, to recover the sum of \$67,245.03, the amount of a judgment in favor of Colin A. Chisholm, as trustee for the bondholders. The properties are the Carbonate Queen and Dead Pine, both situated on Battle mountain. The Dead Pine has been producing ore under a lease.

The lessees on the Burns property of the Aeacia G. M. Co. have shipped about seven cars per week during May, and the royalties for the month are expected to exceed \$3000. The ore was mined in the seventh, eighth, and ninth levels, and development has opened up new orebodies, to replace the tonnage hoisted.

The gold production of Cripple Creek for the month of May was \$1,263,245, as against \$1,216,693 for April. The tonnage was 76,800, compared with 77,281 tons treated the month before. The following is the table of production:

Plant.	Tonnage.	Av. Val.	Total.
Smelters	3,963	\$65.00	\$ 256,395
Golden Cycle	34,100	21.00	716,100
Portland	9,500	21.00	195,000
Colburn	2,860	2.50	7,150
Stratton's Independence ..	10,851	3.16	33,436
New Portland	14,400	3.51	50,644
Wild Horse	1,000	3.20	3,200
Kavanagh	300	4.00	1,200
Total	76,800		\$1,263,345

The Portland mill at Colorado Springs has been changed from a chlorination mill to a modern plant for the cyanide process. The second unit was started May 8, giving the mill a capacity of 11,000 tons per month. G. M. Taylor, the manager, says that comparisons with the former process are not possible as yet. The Blue Flag cyanide mill, owned by the Blue Flag M. & M. Co., will start operations by July 1 with a daily capacity of 150 tons. The

Isabella mill will also start in June and will re-treat an old tailing dump said to average \$1.50 per ton.

IDAHO

BONNER COUNTY

The Golden Scepter Mining Co. has awarded a contract for 100 ft. of development work. This will extend the main drift from No. 5 cross-cut toward the main ore-shoot, which is estimated to be 200 ft. ahead. The workings now have a depth of 700 feet.

COEUR D'ALENE

The Federal, Bunker Hill & Sullivan, Hecla, and Hercules mining companies have acquired the overflow valley of the Coeur d'Alene river to Coeur d'Alene lake, in northern Idaho, for \$100,000. This eliminates the damage suits instituted by farmers who claim that their property has been ruined by the lead in the water, which has run through the concentrating mills before reaching the river. The Caledonia mine at Kellogg is reported to have found an important body of ore in the raise between

Pilot Butte company have subscribed \$100,000 for development and the purchase of new machinery for this property. The shaft is now at a depth of 1100 ft. and will be sunk to a depth of 2000 ft. before any cross-cutting is done. At this depth the management hopes to reach the rich orebodies found in the Berlin claim of the North Butte. A shipment of concentrate has been made from the first unit of the Butte & Superior concentrator to the zinc smelter at Bartlesville, Oklahoma. A new electrically driven air-compressor with a capacity of 5000 cu. ft. of free air per minute has been ordered by this company for two weeks' delivery. It will furnish air for 60 drills. The copper production of the Anaconda company for the month of May is estimated at 26,500,000 lb., of which the Washoe smelter turned out 20,000,000 lb. and the Great Falls smelter 6,500,000 lb. Included in the Washoe output was 2,000,000 lb. from the North Butte and 750,000 lb. from the Tuolumne company. The East Butte smelter produced about 1,250,000 lb., and of this amount about 600,000 lb. belonged to the Butte-Alex.

BUTTE MINES.

the 700 and 800-ft. levels. Charles McKinnis, the manager of the mine, reports that the ore has been followed for 160 ft. and is not yet fully exposed. Samples taken in the raise have assayed as high as 700 oz. in silver, 1.8% lead, and 22.8% copper per ton. Some of the ore in the drift on the 700-ft. level went as high as \$63.5 oz. silver and 22.4% copper per ton.

Work has been resumed on Sunset mine, near Wallace, owned by William A. Clark. Loads of machinery and supplies have been sent in and preparations are made for developing the property. The principal work at present is the sinking of a shaft from the end of an adit. This, it is said, will be driven 800 ft. or more, directly on the ore, to determine whether a lower adit is needed for working the mine.

SHOSHONE COUNTY

Earnings for the Federal M. Co. for the first quarter of 1912 amounted to \$218,000. Thomas A. Edison is experimenting on a method to treat the refractory ores from the Morning mine of the company.

MICHIGAN

The Calumet & Hecla is building a new re-grinding mill at Lake Linden. A building some 300 ft. long is to be erected and Huntington re-grinding mills installed.

MONTANA

SILVERBOW COUNTY

(Special Correspondence.)—Butte men interested in the

Scott. This brings the total output of the district to about 27,800,000 pounds.

Butte, June 1.

The Butte Miners' Union has rejected, at a mass-meeting, the latest proposal of the Anaconda company to fix the scale of wages at \$3.75 per day for all underground men when the price of copper is 15½¢. per pound and \$4 when the price of the metal is 17¢. per pound. The miners demanded a flat increase of 50¢. per day, bringing the wage scale of the shoveler in the mines up to the grade of the more experienced miner.

The annual report of the East Butte M. Co. will be presented at the meeting on June 11. In the year ended March 31 the company produced approximately 13,000,000 lb. of copper, more than 400,000 oz. of silver, and 20,000 oz. of gold. The cost of producing copper averaged about 9¢. per pound in New York. The first-class ore of the East Butte company during the year averaged over 7% copper and the second-class ore about 3 per cent.

NEVADA

ESMERALDA COUNTY

(Telegraphic Correspondence.)—The May production of the Goldfield Consolidated is estimated at 30,209 tons. The gross value of this output was approximately \$500,000, and the operating expenses of the company \$200,000, leaving the net earnings for the month \$300,000.

Goldfield, June 3.

The newly discovered orebody in the 250-ft. level of the Florence mine has supplied ore for shipment to the Western Ore Purchasing Co. D. D. Dewey, superintendent of the Florence, states that the vein has been opened for a length of 30 ft., and that both faces show about 3 ft. of high-grade ore, with samples going as high as \$2000 per ton, and an average value between \$200 and \$500 per ton. A body of milling ore about 8 ft. wide forms one wall of the high-grade streak. This vein is about 1000 ft. east of the shaft of the Florence, in virgin ground, and from the work done so far appears to be almost vertical. Mr. Dewey believes that the vein was worked, above the present discovery, by old lessees on the Jumbo claim.

The miners in the employ of the Pittsburg Silver Peak G. M. Co. went on a strike June 1 rather than adopt the reduced wage scale proposed by the company. W. A. Bradley, manager, reports the camp orderly and 60 of the 120 stamps dropping. The mine staff, including foremen and shift-bosses, who were unaffected by the reduction, will continue to work the mine. A new crew is handling the tramway which conveys the ore from the mine to the mill. There is a large tonnage of ore broken in the stopes, and the present force can supply 60 stamps in the mill for some time.

The full report of the Goldfield Consolidated Mines Co. for April shows the operating costs distributed as follows:

Development	\$0.87	
Stoping	2.28	\$3.15
Transportation	0.10	
Milling	2.10	
Marketing	0.20	
General expenses	0.32	
Bullion tax	0.18	
Marketing ore shipped.....	0.12	
Construction	0.25	
Total cost of operation.....	\$6.53	
Miscellaneous earnings	0.10	
Net cost per ton.....	\$6.43	

The net cost for March was \$6.61. Development for April amounted to 3369 ft. In the Combination the 311-P raise, together with the 200 and 205 drifts in the Reilly orebody, produced 295 tons of ore averaging \$80 per ton. The 111-M sill of the Mohawk was extended and produced about 50 tons of \$26 ore. The 30 drift on the 150-ft. level produced 45 tons of \$23 ore. The 3-E sill produced 195 tons of ore averaging \$12 per ton, and the 407 sill on the 600-ft. level southwest of the shaft was considerably extended, and produced 250 tons averaging \$12.80 per ton. Development in an intermediate below the 250-ft. level, under 111 stope gave promising results. At the Clermont, the sill of the 428 stope, south of the shaft, was extended and produced 350 tons of \$75 ore. The 700-M stope, opening between the 1000 and 1200-ft. levels, produced 500 tons of ore averaging \$39.60 per ton. In the Laguna the shaft has been completed to the 720-ft. level, where a station and sump are being cut and from which point drifts may be driven both north and south.

LINCOLN COUNTY

Diamond-drills have been used in prospecting the Golden Prince property of the Pioche Coalition company. The last hole drilled reached a depth of 400 ft. and cut on its way 31 ft. of iron manganese ore. Other drill-holes which have been driven have all penetrated ore, one body being 20 ft. thick.

LYON COUNTY

The Nevada Douglas has increased its output and shipped to the Mason Valley smelter 11,700 tons of ore in May. Development is reported to be keeping the orebody well ahead of shipments.

NYE COUNTY

A report recently issued by the White Caps mine at Manhattan, gives the company 10,000 tons of developed milling

ore, and 7500 tons additional in what is known as the east ore-shoot, making a total of 17,500 tons.

WHITE PINE COUNTY

At the new shaft of the Giroux Con. M. Co. the only work is the handling of about 1200 gal. of water per minute from the 1400-ft. cross-cut and the shaft below that point. The water from the shaft is pumped to the sump in the 1400-ft. station and from there to the big pump in the 1200-ft. station which elevates it to the surface. No work is being done away from the shaft stations. Development is concentrated at present in the Morris and Bunker Hill mines, on the opposite side of the hill from the Giroux shaft, in an attempt to bring the production up to 1000 tons of ore per day. At present only four or five cars of ore are shipped each day to the smelter at McGill, but a large force of men is at work underground putting the mines in shape to produce more rapidly. The surface equipment at the Bunker Hill will not be completed for several weeks, but a force of carpenters and mechanics is at work there.

NEW MEXICO

GRANT COUNTY

The Chino Copper company mines have been closed by a strike of the steam-shovel crews and the train crews operating the locomotives and ore trains. The men demanded an increase in wages, which the company was not willing to grant.

SOCORRO COUNTY

(Special Correspondence.)—The old ore-bins at the Treasure M. & R. Co. were destroyed by fire on May 25 and the entire mine crew was put to grading for new ones, which will be in commission within a few days. A good ore reserve at the mill will prevent a shut-down. The Ernestine M. Co. reports that two clean-ups for the first 20 days of May yielded 21,725 oz. gold and silver bullion and 22,550 lb. of high-grade concentrate. This is the best 20-day record of the company. The past week's ore treatment was 698 tons. At the Deadwood mines 30 ft. of development was done in the mine. The mill treated 320 tons of ore during the week, producing 18 sacks of concentrate. The Pacific and Johnson mines of the Oaks Co. shipped 30 tons to the Deadwood mill from 21 ft. of development during the week.

Mogollon, May 31.

PENNSYLVANIA

(Special Correspondence.)—The Safe Harbor Iron & Steel Co. has been financed in New York to acquire and operate the Martie iron mines in south central Pennsylvania near Lancaster. This undertaking is notable for the very low grade of the ore which it is proposed to mine and treat. The deposit consists of hornblende schist with magnetite and has an average content of less than 20% iron. About 7,000,000 tons of iron-bearing rock has been proved by drilling, and it is expected that the deposit is much larger. The tests made indicate a satisfactory saving by magnetic concentration, the tailing containing not over 1/2% magnetite and the product running from about 60% iron with low sulphur and phosphorous content. It is proposed to sinter the concentrate, although experiments now being made indicate the practicability of electric smelting of the product to produce steel. A capacity of 1000 tons of product daily is proposed. A plant is now installed on a spur connecting with the Pennsylvania railroad at Safe Harbor.

Lancaster, May 22.

UTAH

SALT LAKE COUNTY

The Bingham Mines Co. has resumed work on the Yosemite, and two shifts of miners have started sinking a shaft to connect with the Mascotte adit. A raise has already been driven 280 ft. from the adit, and when the connection is made the shaft will be 2220 ft. in depth on the incline. From the 800-ft. level and above, the old Yosemite company produced about \$1,000,000 worth of

ore. No development has been done below the 800-ft. level and the Bingham Mines Co. hopes to find large bodies of lead and copper ore in the ground to be opened by the new shaft.

The International S. & R. Co. has ordered material for the third lead stack at the Tooele smelter, and at the site construction work has already commenced. The fourth reverberatory is in operation at Tooele, and the lead and copper plants are smelting 1000 tons per day.

The Mines Operating Co. has taken a ten years' lease on the property of the Ontario Silver M. Co. and is remodeling the Ontario mill for the treatment of low-grade ores by a cyanide process similar to that which has proved successful at Mercur. The Ontario has a production record of nearly \$50,000,000 and a dividend record of almost \$15,000,000. In the early operation of the mine, only the high-grade ore was hoisted, and poorer ore was stored in the stopes. It is estimated that the mine has 1,000,000 tons of ore blocked out and stored in the old stopes which will average over \$8 per ton. A recovery of 80% is expected from the remodeled mill at a cost of \$6 per ton.

SUMMIT COUNTY

The annual report of the Silver King Coalition Mines Co. shows cash in the treasury April 30, the end of the fiscal year, to the amount of \$410,000, after \$100,000 had been spent in electrifying the mine, the purchase of motors, straightening drifts, and replacing old rails with heavier ones. An increased production is planned for the ensuing year. The Mayflower property of the Silver King has been worked by lessees for the past two years. This mine is still producing a small amount of rich ore from a few thin veins and the lessees are encouraged by the company, in the hope of finding a large body of ore.

The John the Revelator property, which is worked by Sam Hair under a lease, has produced rich carbonate ore in May. An incline 60 ft. in depth has been driven in this ore and the vein still shows about two feet wide in the bottom of the shaft. The hanging wall is limestone and the foot-wall quartzite.

CANADA

BRITISH COLUMBIA

The Red Cliff Mining Co. has secured an option on the controlling interest in the stock of the Tyee Copper Co., Ltd., owners of the smelter at Ladysmith, Vancouver Island. One of the most valuable assets of the Tyee Copper company consists of a perpetual coke contract, at a stated price. Since this contract was secured the price of coke has advanced, and should the Red Cliff company complete the deal, it will effect a saving in the cost of reducing the company's ore, as well as allow a handsome margin of profit over cost of treatment at other customs smelters on the coast. About \$500,000 is involved in the transaction.

ONTARIO

(Telegraphic Correspondence.)—The town of Cobalt has been swept by fire, which at last reports was not under control. The Canadian Pacific Railroad Telegraph Co. at Montreal gave out the news early this morning, but since then direct telegraphic communication with Cobalt has been cut off.

Montreal, June 6.

The Hollinger mill in Porcupine has placed an order for 10 additional 1500-lb. stamps for July delivery. This will make a total of 50 stamps for the Hollinger, and will give the Hollinger the largest capacity in the district. At the time construction was started, the cyanide mill was made large enough to take care of a possible addition to the crushing department. The Dome mill is now operating at full capacity. The tube-mill, which has been the principal cause of delay, has been repaired, and the only shut-down now necessary is to clean the plates, and then only one battery out of five is thrown out of gear. The West Dome mine has closed down, on account of shortage of fuel, but is expected to be in operation again by July 1, with either coal or electricity for power. The Nipissing Mining company has started hydraulic operations to remove the over-

burden from certain claims and make it possible to find any outcropping veins which may exist. The water is raised from Cobalt Lake by an electric pump. About two acres have been washed by this method, and several small cobalt outcrops uncovered. The company intends to prospect several hundred acres by this method.

JAPAN

(Special Correspondence.)—The most serious disaster that has ever occurred in the coal mines of Japan happened about 11 a.m., April 29, in one of the mines of the Tanko Kisen Kaisha (Coal Mine & Steamship Co.) operating in Hokkaido. An explosion of fire-damp in No. 2 incline led to the death of all the men underground at the time, 266, and of 7 men at the surface. A great gust of gas came to the surface, wrecking buildings and blowing out mine-cars. The noise of the explosion was heard for a considerable distance. Following the explosion, fire was found in levels No. 1 and No. 2, and there were finally stopped off with brick walls after great difficulty. No fire was found in the other levels, and rescue parties were able to recover bodies. The mine will be idle for some time, as machinery as well as buildings was destroyed. This will reduce the output of the company, which is a serious matter for it, since, in addition, the widows and orphans of the men killed must be cared for. The company is making generous provision for them. The cause of the explosion has not been ascertained.

Tokyo, May 14.

MEXICO

CHIHUAHUA

The annual report of the Alvarado M. & M. Co. for 1911, together with a supplementary report for the three months ended March 31, 1912, has been issued. The revolution interfered greatly with the operations of the company during 1911, but a profit of \$106,468 was earned. The supplementary report shows a profit of \$58,961 for the first three months of the present year. Conditions are still unfavorable for the operation of the mine. It has been impossible to move any freight into Parral since early in the month of February, and since the middle of April there have been no banking facilities. Almost all the mines and mills in the Parral district have been closed, and the Alvarado has been enabled to run by having large amounts of supplies on hand when traffic was interrupted. Under normal conditions the Alvarado mine should be able to increase its earnings, as a large body of good ore is blocked out and a constantly increasing tonnage is being hoisted. The water from the mines is handled with-out difficulty.

JALISCO

(Special Correspondence.)—The El Tajo M. Co., at the suggestion of the manager, Ferdinand McCann, has decided to close the mill until connection has been made between the lower and upper workings, which will materially diminish the cost of mining. While this connection is being made, the lower portion of the vein will be thoroughly explored, and if the results are as anticipated, the mill will be enlarged to a capacity of 100 tons per day. electric power will be introduced, and many other changes made with a view to diminishing the cost and increasing the extraction in treatment. In the meantime, Mr. McCann has severed his connection with the company and intends to go to the City of Mexico, opening an office as a consulting engineer.

San Sebastian, May 28.

SONORA

The Greene-Cananea company has recently acquired a large interest in the Sonora Bonanza, a property situated on the main line of the Southern Pacific in Mexico, south of Nogales, Arizona. The mine is said to have a large amount of gold ore averaging \$10 per ton, and carrying a large percentage of silica. The company has been anxious to obtain silicious material to smelt with the basic ores produced in its own mines, and the Bonanza property was regarded as a valuable acquisition and one which would facilitate the desired metallurgical results.

Personal

Professional men are invited to send news of their engagements and travels. Such news is interesting to friends.

H. G. PEAKE is in London.
F. W. BRADLEY is at Kellogg, Idaho.
J. R. FINLAY has been in Wisconsin.
JOHN B. FARISH is at the St. Francis.
HENRY P. CHANDLER has gone to Nome.
H. D. McCASKEY has been in San Francisco this week.
R. H. ELLIOTT has returned from West Africa and London.

J. P. SMITH has gone to Shasta county for geological work.

ALEXANDER McLEOD is at Orangedale, Cape Briton, Nova Scotia.

J. W. STIMMONS, of Glendale, Oregon, is at Seward, Alaska.

W. H. LANDERS has returned to San Francisco from Nevada.

FREDERICK E. BROWNE, of Salt Lake City, is at Hart, California.

BYRON E. JAMES has returned from Mexico and is at Nevada City.

A. C. VEATCH has gone to Tampico, Mexico, from Washington, D. C.

NORMAN N. BLYE is with the Con. Mercur G. M. Co. at Mercur, Utah.

J. C. NICHOLLS has returned to San Francisco from South Porcupine.

OSCAR H. HERSHEY has returned to Kellogg, Idaho, from southern California.

TADASHIRO INOYE, of the Imperial University of Tokyo, is in Berlin, Germany.

R. C. SPECHT is engaged in examination work in Trinity county, California.

FRED T. WILLIAMS has been in California and Arizona on professional business.

S. L. G. KNOX is vice-president and general manager for the Natomas Consolidated.

F. CUSHING MOORE, formerly of Payette, Idaho, is at Walla Walla, Washington.

SUMNER S. SMITH left Juneau on June 2 for the interior of Alaska, by way of Dawson.

F. G. CLAPP has been in California and has gone to Alberta to examine oil properties.

H. NORTON JOHNSON is general superintendent for the Consolidated Goldfields, Reefton, New Zealand.

F. M. CHAMBERS, of Goldfield, is representative for the International Smelting & Refining Co. in Nevada.

ROLLA E. CLAPP is making a geological examination of the Railroad mining district, Elko county, Nevada.

DAVID MORGAN has gone to Long Beach, California, for the summer and will return to Arizona in September.

H. J. MIESEL has been appointed superintendent for the Independent Lead Silver Mining Co., Keeler, California.

J. B. TYRRELL has arranged with S. N. GRAHAM to carry on his professional work during his absence in the North.

W. R. BASSICK has succeeded S. L. G. KNOX as vice-president and general manager for the Yuba Construction Company.

FERDINAND McCANN has resigned as manager for the El Tajo Mining Co., and will open an office as consulting engineer in Mexico City.

GEORGE MILLER, formerly with the Mexican Mines Co. at Bolanos, Jalisco, Mexico, is now with the Liberty Bell mine, Telluride, Colorado.

HOWLAND BANCROFT has resigned from the United States Geological Survey and has engaged in consulting geological practice at 730 Symes building, Denver.

W. W. JOHNSON, C. C. WEBSTER, P. D. WINTER, JOHN S. KIMBALL, CHARLES KIMBALL, J. S. JOHNSTON, J. D. CAMPBELL, G. H. RUSSELL, W. M. WITHER, and S. W. BEARDSLEY were among those sailing on June 1 from San Francisco for Nome on the *Umatilla*.

Anaconda Copper Mining Company

The report of the Anaconda Copper Mining Co. for the year ended December 31, 1911, is chiefly remarkable as an exhibit of the strong position and wonderful resources of the company, thus enabling it to produce copper at a profit, from the deep orebodies at Butte, even in a year of low prices for copper. The combination of the Butte companies has evidently increased efficiency in each branch and led to economy in the actual working of the mines and smelters. The greatest gain, however, seems to be due to the fact that all of the Anaconda's far-reaching interests are now controlled by a single policy. During the year 1911 the policy of the company dictated a curtailment of the copper output, while reconstruction work and extraordinary repairs were carried on, which left the mines and smelters in better shape than at the beginning of the period and in position to add greatly to their output whenever the market conditions warrant.

Development was carried on at a normal rate throughout the year, and several new orebodies opened in the lower levels of the mines. The total amount of ore developed was in excess of the amount extracted. In the Anaconda department ore was hoisted principally from the Mountain Consolidated, Diamond, Original, Steward, and West Gray Rock shafts. The Anaconda shaft was out of commission for the entire year, and was thoroughly repaired to the 2400-ft. level. The St. Lawrence shaft was also repaired, but sinking and hoisting operations were resumed in May. At the High Ore, Belmont, Diamond, and West Gray Rock new cylinders have been placed in the hoisting engines preparatory to their operation by compressed air. At the Diamond and West Gray Rock the change has been found satisfactory, and the management is confident of complete success in this particular. The Gagnon and East Gray Rock shafts have been closed permanently and are to be used as air shafts. The Never Sweat will also be closed for ore, but still used for lowering men and timber and for ventilation. The shafts of the Anaconda, St. Lawrence, Mountain Consolidated, Belmont, and West Gray Rock will be sunk deeper, and connections made in the lower levels to aid in the ventilation of the underground workings. The water from these mines will all be drained into the High Ore shaft, which will do the greater part of the pumping for the district. The Anaconda is now draining into the 2800-ft. level of the High Ore through diamond-drill holes, and the Diamond and Poulin mines are unwatered through cross-ents into the High Ore workings. At the High Ore the fire in the stopes threatened serious loss for a time, but after a fight of three months was put out in April. Skips were substituted for cages at this shaft and ore pockets cut on the 1600, 1800, 2200, 2400, and 2800-ft. levels. Three electrically driven quintuplex vertical cylinder pumps were installed on the 1200-ft. level, and three similar ones on the 2200-ft. level, each pump having a capacity of 600 gallons per minute. The power-lines were carried down an auxiliary shaft, and the steam pumps will be maintained in case of accident.

In the Boston & Montana department, development was carried on throughout the year, and the ore reserves were not depleted by hoisting. New air-cylinders were placed in the engines at the Mountain View shaft, and the hoists at the Leonard and Pennsylvania will be changed over in 1912. Cross-ents were driven to connect the lower workings of the different mines as an aid to ventilation, and the shafts on the Tramway and Buckley mines deepened. All told, the Anaconda company did 30.7 miles of development during the year and sank the shafts an additional depth of 3711 ft. The total amount of ore hoisted during the year was 3,844,070 tons, and in addition 4602 tons of copper precipitate was produced. The Great Falls Power Co. furnished power for the mine operations throughout the year in a satisfactory manner, and the engineers of the company anticipate a great saving in operating cost in the displacement of steam by electric power and in the use of electrically compressed air in the hoists.

The reduction works treated for all companies during the year 3,154,036 dry tons at Anaconda and 1,101,778 tons at Great Falls. Of this amount, 599,578 tons was purchased from other companies. The Washoe production was 191,573,780 lb. of copper, 8,510,122 oz. of silver, and 40,546 oz. of gold, while the Great Falls production was 67,833,313 lb. of copper, 1,221,439 oz. of silver, and 8404 oz. of gold. The total production was 259,407,093 lb. of copper, 9,731,561 oz. of silver, and 48,950 oz. of gold.

At Anaconda tests were carried on with a large centrifugal concentrating unit, which gave promise of good results when certain mechanical imperfections in the machine are overcome, so that it will operate continuously. Experiments which have been carried on for years in the concentrator at Great Falls, tending toward a higher recovery from the ores treated, have finally been successful. One full section has been equipped with new machinery and operated continuously, with such promising results that the whole mill at Anaconda will be changed over, section by section, to conform with the new flow-sheet. The new method will not only increase the saving, but also the capacity of each section.

From the coal mines of the Anaconda company in Montana and Wyoming over 800,000 tons of coal was produced, largely for use in the other departments of the company. The lumber department cut at the mills 90,000,000 ft. of lumber, the greater part of which was sold. These subsidiary departments of the company show profits of \$256,301.55.

The Butte, Anaconda & Pacific railway has planned the electrification of the road from the Butte mines to Anaconda, and an extension of the road to the Georgetown district to provide transportation facilities for several low-grade mines in that district. The railroad handled 4,659,696 tons of ore and freight, and 191,797 passengers during the year, earning a profit of \$46,944.28.

An analysis of the financial statement of the company shows the cost of mining to have been \$3.77 per ton of ore, transportation costs 32c. per ton, and the average cost of reduction \$1.82 per ton. The cost of producing, shipping, and selling copper was about 11.77c. per pound, which, after deducting a credit of 2.37c. for gold and silver, leaves 9.4c. per pound as the net cost of the Anaconda production. These costs include all the charges for repairs, development, and construction for the year. The balance sheet shows the fixed assets of the company, including mines, reduction works, townsite property, all buildings and machinery, timber lands, and investments in sundry companies, to be \$95,028,477.98. The deferred assets, materials, and supplies for future operations, and insurance paid in advance amount to \$2,779,782.91, while the current assets are merchandise and metals held for sale, accounts receivable and cash to the amount of \$20,334,528.57. The total assets on January 1, 1912, were \$118,142,789.46. The total profits for the year, after deducting interest charges, were \$8,043,718.76. The four quarterly dividends amounted to \$8,608,750, exceeding the profits by \$565,031.24. B. B. Thayer, president of the Anaconda company, states in the report that this difference was more than offset by the item of extraordinary repairs and expenditures, in excess of normal years, which amounted to \$583,462.27, all of which was charged directly to operations during the year 1911, and not carried for future proportionate distribution.

James Lewis & Son's Copper Report

Standard copper varied in value £1 per ton during the first 16 days of May. The opening on May 1 was £70 2s. 6d., from which it fell to £69 on May 3. A recovery was made to £69 5s. 0d. on May 6, followed by a decline to £68 18s. 9d. the next day. The American statistics announced on May 9 proved more favorable than expected, bears anxiously covered their previous sales, and speculators bought freely, resulting in an advance to £73 for three months prompt delivery on May 14. On May 15 realization of profits caused a drop to £72 for cash, and

£72 7s. 6d. for three months, warrants for free delivery being offered in limited quantities. On May 16 the publication of favorable statistics advanced the market to £73 cash and £73 10s. 0d. for three months. Sales for the fortnight totaled 27,000 tons. Large sales of electrolytic copper are reported to American consumers at up to 16½c. per pound, a considerable quantity being also taken for export at £74 to £74 10s. 0d. per ton c. i. f. With continued large deliveries from Europe, the quantity available there in stock is much reduced, and some anxiety is felt as to supplies proving sufficient for future requirements in view of the greatly increased consumption in the United States as well as in Europe.

In the last four months there has been an increased import into the United States of 5532 tons, but a decreased import into Europe from other countries of 9554 tons, or a total diminution in supplies of 4022 tons. The consumption of the United States has increased 19,861 tons and that of Europe 17,738 tons. Exports from the United States have increased 15,990 tons and from Europe have decreased 2717 tons, those from England having fallen off 3564 tons, chiefly due to the coal strike. Stocks in the United States and Europe have together diminished to the extent of 20,803 tons in this period, whereas last year in the same time they increased 14,477 tons, although the total decrease for the year 1911 was 43,082 tons.

In the past fortnight, stocks including Germany and Holland have decreased 3075 tons and the visible supply 4350 tons. The arrivals in England and France have been 6559 tons and the deliveries 8892 tons. The arrivals at Liverpool and Swansea from the United States have been 1077 tons bars, and 435 tons plates, equal to about 1510 tons fine, in London 75, and in France 2100 tons fine. The arrivals of Chile in Liverpool and Swansea have been 1123 tons, and the deliveries 1119 tons, and from other countries 795 and 859 tons fine respectively. The Chile charters for the past fortnight are advised as 650 tons, including 175 tons to the United States.

Total imports to date this year are 6629 tons, and deliveries 4296 tons less than last year. These latter include 3400 tons shipped to the United States, as against 6200 tons last year.

Quotations May 16 were: Standard copper £73 0s. 0d. for cash and £73 10s. 0d. for three months' prompt; electrolytic wire bars, £75 0s. 0d. to £75 10s. 0d. net, e. i. f.; English best selected ingots, £77 0s. to £78 0s. per ton, and tough cake £77 0s. to £77 10s. less 2½%, ore of 20% 12s. 9d. to 13s. 0d., and regulus and matte 13s. 3d. to 13s. 6d. per unit.

Decisions Relating to Mining

Specially reported for the MINING AND SCIENTIFIC PRESS.

OIL WELLS—INJURY TO ADJOINING REALTY ENJOINED

The pumping of oil and salt water from oil wells, and permitting it to flow on lower adjoining lands so as to accumulate and stand in pools and destroy the crops and timber thereon, and to permanently injure the productiveness of the soil, and cause noxious odors, is an actionable injury, which may be enjoined.

Niagara Oil Company v. Ogle, (Indiana) 98 North-eastern 60, April 3, 1912.

MEASURE OF DAMAGES FOR TAKING COAL

Defendant was the owner of coal land adjoining a tract belonging to plaintiff. Having no facilities for mining the coal he executed a lease to other parties on a royalty basis, authorizing them to mine under defendant's land. The lessees unintentionally pushed their workings across the boundary and extracted large quantities of coal from beneath plaintiff's land. Held that the measure of damages for which defendant should be assessed was a reasonable royalty of 7c. on all bituminous and 25c. on all cannel coal wrongfully extracted.

Lyons v. Central Coke & Coal Co., (Missouri) 144 Southwestern 503. February 6, 1912.

READJUSTING BOUNDARIES—EFFECT OF EXCLUDING BOUNDARY POINT

Where a placer location was unintentionally made to cover a trifle more than 20 acres, and subsequently the boundary lines were drawn in to correct the error, if the locator in so readjusting his boundaries leaves his only point of discovery outside of the new lines, he thereby invalidates his entire location by leaving it without a mineral discovery. A United States mineral surveyor is, by virtue of his office, disqualified from making mining locations or acquiring any interest therein during his tenure of office.

Waskey v. Hammer, (U. S. Supreme Court) 32 Supreme Court Reporter, 187. January 22, 1912.

OIL CONTRACT—RIGHT OF GRANTOR TO RECOVER

Where a contract granted the exclusive right to explore land for gas and oil and provided for the payment by the grantee of 50c. per acre per annum, after the first year, until a well should be completed producing gas in sufficient quantities to justify marketing it, it is not essential to the right of the grantor to recover such sum to show that the grantee ever took or held possession of the land under the contract. As long as said contract was in force the grantee had the right to enter upon said land and prospect for natural gas and oil and he is liable for the compensation fixed in the contract for this privilege until the contract is cancelled.

Kokomo Natural Gas & Oil Co. v. Matlock (Indiana) 97 Northeastern 787. March 6, 1912.

ASSOCIATION CLAIM—EFFECT OF PART CONVEYANCE PRIOR TO DISCOVERY

Where eight persons made an association location of 160 acres of oil land, and thereafter conveyed a portion of their claim to a ninth person in consideration of his performing the exploration work necessary to perfect the location, the performance of such work by the grantee upon the portion of the claim conveyed to him or his grantee inures to the benefit of the entire 160 acres. The only difference between such a grantee and one to whom a conveyance of a segregated portion has been promised upon a discovery by him sufficient to perfect the location is that the grantee has been paid his consideration in advance. In both cases the work is being done for the benefit of all the associates and of the whole claim.

Merced Oil Co. v. Patterson, (California), 122 Pacific, 950. March 22, 1912.

Concentrates

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

TRANSVAAL mines, June 30, 1910, employed 257 air-compressors with a total horse-power of 100,291, while 400 hp. of compressed air was purchased.

ARIZONA, though it has produced no coal on a commercial scale, contains large areas of workable beds, according to the U. S. Geological Survey.

MONTANA, in 1911, according to E. W. Parker, produced 2,975,358 tons of coal, worth \$5,339,058. This was a slight increase over the output for 1910.

PHOSPHATE ROCK has been found in central Kentucky and, according to F. B. Van Horn of the U. S. Geological Survey, a considerable production from this area is to be expected.

ZIRCON is used in the manufacture of electric lamps, as an insulator for electricity and heat, in making refractory crucibles, in lining electric furnaces, in making paints, and as an abrasive.

OIL of remarkable purity has been found at Pine Prairie, Louisiana. It contains no asphalt, gasoline, or paraffin wax. The crude product contains a large percentage of illuminating oil.

POTTERY was made and marketed in the United States to a total value of \$34,518,560 in 1911, according to Jefferson Middleton of the U. S. Geological Survey. The largest amount came from Ohio.

BEARING and pinions made of manganese steel are used in the tube-mills of the Goldfield Consolidated mill. The gears have been in service for three and a half years now and seem good for two more years. The pinions last two and a half years.

COST of electric power varies enormously, but the following figures may be quoted, they being in cents per kilowatt-hours: Pennsylvania railroad, 0.58; Long Island, 0.697; West Jersey & Seashore, 0.592; Interboro Rapid Transit, 0.543; Twin City Rapid Transit, 0.62.

METAMORPHISM of olivine to serpentine is accompanied by increase in bulk. In the case of one of the South African diamond pipes it is figured that since the surface presented the only free end, the increased bulk necessitated a vertical movement of approximately 800 feet.

SCRAP MICA is ground in large quantities and used for the decoration of wallpaper and in the manufacture of lubricants and fancy paints; it is also molded for electrical insulation. When mixed with grease or oils, finely ground mica free from gritty matter forms an excellent lubricant.

MEERSCHAUM is mined almost exclusively in the vicinity of Eski Shehir in Asia Minor, about one day's journey by rail from Constantinople. It occurs in nodular form in clays, and has been mined for a thousand years. It is sold principally through Vienna merchants, and the annual exports from Turkey are estimated to be worth \$260,000.

NITROGLYCERINE begins to decompose at temperatures as low as 50°C. Snelling and Storm, of the Bureau of Mines, have recently conducted experiments on the behavior of nitroglycerine when heated, and were able, by careful work, to decompose it and char the residue with-

out explosion. The experiment is not recommended for amateurs.

IN DRAWING down a superincumbent mass of dirt, as is necessary often when driving beneath caved ground, many operators endorse the system of effecting an opening for the descent 10 or 12 ft. back from the heading, thus leaving the ore face unimpaired. Where repeated pulling of the ground is required they favor pushing the heading on in advance of the openings through which the dirt is drawn down.

BURNING of coal and wood in a mine fire differs in some respects from the ordinary combustion of coal or wood in a boiler furnace; yet, just as periodic analyses of the escaping gases will indicate combustion conditions in the furnace, so periodic analyses of the atmosphere within a burning mine or section of a mine will indicate combustion conditions there, although these indications are less clearly understood, and will be until some features of mine fires have been studied more fully.

HOISTING TIME increases with depth, but not in proportion to the depth. Since the starting and slowing absorbs a constant amount of time whether the hoist be long or short, each additional level is gained with a decreasing added increment of total hoisting time. At Kimberley in South Africa, when hoisting from 1000 ft., 30 sec. per skip was necessary. When hoisting from 2500 ft., the time became 59 sec., and when the skip was sent to 3500 ft., the increase was only 11 sec., or a total of 70 seconds.

WHEN an entire mine, or a section of it, has been sealed to exclude air, the sampling of the atmosphere within the sealed area becomes desirable in order to determine the effectiveness of the stoppings or dams in excluding air. If the stoppages are tight, the fact is shown by a depletion of oxygen in the atmosphere behind them. A period of anxiety always follows sealing, and any aid that tends to allay fears as to whether the fire is spreading or enables the mine officials to act promptly in case conditions get worse, is worthy of consideration. The U. S. Bureau of Mines has been studying the analysis of mine gases, as one means of meeting this situation.

ZINC prices abroad are controlled by a 'Zinc Convention,' formed first in 1909, and which has gradually come to include practically all the leading producers. By this convention the production, within certain limits, was at first allotted in advance to the various members. If the market showed signs of over-production the output was curtailed pro rata. The basis price for metal was fixed at the equivalent for 4.11c. per pound. In 1910 the convention was continued to 1914, but the restriction clause was changed. Under the new rule there was to be no restriction so long as the total stock of spelter did not exceed 50,000 metric tons, or the London price fall below £22, equivalent to 4.8c. per pound. Should either occur, production was to be restricted pro rata on the basis of the output of each smelter for the last preceding quarter.

DIAMONDS are sold all over the world, but approximately 60% of the output is absorbed in the United States. In 1907, when there was a financial crisis here, the demand at Kimberley fell off 75% and many men were thrown out of work. Other countries are much richer than the United States, but their wealth represents accumulations of previous years. Diamonds and jewels have already been bought and are handed down from generation to generation. In the United States the wealthy people have generally made their own fortunes and have their diamonds still to buy. It is also true that here it is possible for even poor men to buy good diamonds because of the system of sale on the installment plan. The stones cost the ultimate consumer more, but it is possible for him to meet small monthly payments when he could not pay out the whole cost at once.

Book Reviews

Any of the books noticed in these columns are for sale by, or can be procured from, the MINING AND SCIENTIFIC PRESS.

THE BASIC OPEN-HEARTH STEEL PROCESS. By Carl Diehmann. Translated and edited by Alleyne Reynolds. Pp. 329. D. Van Nostrand Co., New York, 1911. For sale by the *Mining and Scientific Press*. Price \$3.50.

This book, according to the author's statement, is intended to answer some of the theoretical questions which arise in connection with the manufacture of steel by the basic open-hearth process. The author, in his twenty years experience, has evidently felt the need of a reference text which would not only summarize the knowledge on the open-hearth process, but would also supply several gaps which have existed in previous literature. The translator has confined himself to a literal translation and to the removal of a few inaccuracies in the original text. The first part of the book deals with the fuels available for the manufacture of producer-gas, and the chemical reactions which take place in the furnace and later in the regenerator chambers of the furnace. Stress is laid upon the thermal conditions in the oxidation of the carbon, in contact with steam, and the influence of the individual reactions upon the final temperature produced. The method of judging the work of producers from gas analysis is taken up, and several examples are given to illustrate the possibility of controlling the work of a producer, the admission of steam and air, and the temperature of the distillation chamber from examination of analyses. The effect of the quality of the gas upon the air required for combustion and upon the transference of heat to the furnace walls is also taken up from the standpoint of the analytical chemist.

The second part of the book deals with the chemical reactions which take place on the hearth of the furnace. The formation of slag, the removal of impurities, and the influence of temperature of the flame upon the work of the furnace are discussed in detail with a number of illustrative tables and charts taken from tests and from actual practice. The last chapters of the book are taken up with a comparison of the different methods used in working the basic open-hearth process, and in urging the advantages of the process from a commercial standpoint. The appendix contains a number of tables and formulae for the use of a gas analyst in determining the composition and heat values of producer gas. The book as a whole shows the result of careful study, and emphasizes the importance of a thorough understanding of the principles which underlie the basic process. To a furnace superintendent the book will be especially useful, but to all students of the steel industry it will appeal as a valuable contribution to the literature available for reference.

Recent Publications

GAS ANALYSIS AS AN AID IN FIGHTING MINE FIRES. By George A. Burrell and Frank M. Seibert. Technical Paper No. 13, Bureau of Mines. Washington, 1912. In the introduction to this paper the authors say: "The Bureau of Mines is conducting, as an essential part of the mine-accidents investigations entrusted to it, an investigation of the factors involved in the origin and spread of mine fires, and of the means by which such fires may be prevented, limited, or extinguished. The authors, in connection with their work on mine gases, have made gas analyses and recorded observations on the condition of the atmosphere in mines. Some conclusions from their work are presented in this paper in the hope that they will be of service to those who may have to fight fires; for, although analyses of the gases from such fires have been made in the past, the systematic analysis of samples of the atmosphere of a burning mine or section of a mine has not received the attention its usefulness warrants. In the early stages of

a mine fire effort is directed toward fighting it at close range by using water from buckets, hose, or portable extinguishers or by loading out the hot coal. Frequently this effort is not successful, and the mine or a section of it is sealed in order to smother the fire. Some fires gain such headway that the entire mine has to be flooded. This expedient, though effective, requires the use of an enormous quantity of water, not always easily obtained, and a subsequent expenditure of much money and time in draining the mine and putting it in working order."

Topographic maps of the U. S. Geological Survey of the quadrangles named below are now ready for distribution:

Gridley, California, embracing parts of Butte and Sutter counties; scale 1:31,680.

Miami Copper Belt, Arizona, in Gila county; scale 1:12,000.

Mount Goddard, California, embracing parts of Fresno, Inyo, and Mono counties; scale 1:125,000.

Randsburg, California, embracing parts of Kern and San Bernardino counties; scale 1:62,500.

BEHAVIOR OF NITROGLYCERIN WHEN HEATED. By W. O. Snelling and C. G. Storm. Technical Paper 12, Bureau of Mines. 14 pp. Washington, 1912. Very little information as to the behavior of nitroglycerin at high temperatures is available, and this investigation accordingly fills a marked gap in technical literature.

Catalogues Received

ALBANY LUBRICATING CO., New York. 'Economical Lubrication.' 32 pages. Illustrated. 4½ by 6½ inches.

LUNKENHEIMER CO., Cincinnati, Ohio. Catalogue covering its line of engineering specialties. 654 pages. Illustrated.

FORT WAYNE ELECTRIC WORKS, Fort Wayne, Indiana. Bulletin 1142, 'Fort Wayne Electric Fans.' 30 pages. Illustrated. 8 by 10 inches.

SPRAGUE ELECTRIC WORKS, 527 West 34th St., New York. Catalogue No. 325, 'Sprague Electric Fans.' 40 pages. Illustrated. 8 by 10 inches.

AMERICAN PULVERIZER CO., 410 Mermod-Jaccard Bldg., St. Louis, Missouri. 'American Ring Pulverizer.' 4 pages. Illustrated. 8 by 10 inches.

KEYSTONE PLACER DRILL CO., Beaver Falls, Pennsylvania. Catalogue No. 6. 'Downie Deep Well Pumps.' 86 pages. Illustrated. 8 by 10 inches.

WESTINGHOUSE MACHINE CO., East Pittsburg, Pennsylvania. Circular WM No. 506, 'Westinghouse Turbo-Alternators.' 40 pages. Illustrated. 7 by 10 inches.

ROBINS CONVEYING BELT CO., Park Row Bldg., New York. Bulletin No. 5, 'Robins System of Coal, Coke, and Ash Handling.' 40 pages. Illustrated. 6 by 9 inches.

TAYLOR IRON & STEEL CO., High Bridge, New Jersey. Bulletin No. 114, 'Application of Tisco Manganese Steel to Crushers and Pulverizers.' 4 pages. Illustrated. 6 by 9 inches.

McKERNAN-TERRY DRILL CO., 115 Broadway, New York. Bulletin covering 'Wizard' Rock Drill. 12 pages. Illustrated. 6 by 9 inches. Also bulletin on heavy-duty pile hammers. 8 pages. Illustrated. 6 by 9 inches.

SULLIVAN MACHINERY CO., Peoples Gas Bldg., Chicago. Bulletin 63 F, 'Sullivan Continuous Coal Cutter'; 32 pages. Bulletin 58 K, 'Sullivan Duplex Air Compressors'; 16 pages. Bulletin 66 F, 'Sullivan Lightweight Rock Drill'; 12 pages. All illustrated. 6 by 9 inches.

UNION CONSTRUCTION CO., San Francisco. 'Catalogue of Elevator Dredges for Placer Mining.' A well printed and illustrated catalogue of dredges for gold and tin, built by this company. Contains interesting matter on tin-dredging and gives operating costs and discussion as to types and sizes. 52 pages. 7 by 10 inches.

MINING men interested in Mexico have all taken heart since the announcement of the completion of the Speyer loan of \$10,000,000 to the Madero government. Silver is at its best price since in the latter part of 1907, the market for the month of May in New York averaging about 60½ cents per ounce. At this price there is a

margin of profit for many properties in Mexico that have only paid expenses or have been operated at a loss for many months, and shareholders and managers alike are eagerly awaiting assurances that Mexican highways are safe. With the waning interest in the Canadian mining districts, there is a large public that will welcome an opportunity to become interested in Mexico. If the present Mexican government can get affairs firmly in hand, the next few years should see a real mining boom south of the Rio Grande.

HOME rule for Alaska is receiving serious attention at Washington. A bill providing for local government has passed the House and has been reported favorably in the Senate. As amended by the Senate Committee, only one legislative chamber is provided, an interesting move toward simplification that seems especially appropriate in the government of a territory having a small and widely scattered population. It is further proposed to establish a local Railway Commission to consist of an engineer officer each from the Army and Navy, and a geologist from the Geological Survey. This would seem to assure expert and disinterested officials for a critical part of the work to be done in the Far North.

MINE inspectors now maintain an active and helpful Institute, which is to meet this year at Columbus, Ohio, June 17 to 21, inclusive. One of the encouraging signs of the times is the raising of standards among state mine inspectors. There have always been some able and conscientious officials in the work, but there have been far too many men who held positions because of their political activity and who were far too narrowly trained. The Mine Inspectors' Institute of the United States is now in its fourth year. It was organized by the Inspectors themselves and is a movement from within, to better themselves and their work. It is accomplishing great good, as must always flow from frank interchange of experience and ideas among men of the same profession. The Columbus meeting promises to be a particularly interesting and profitable one.

PANAMA is not the only centre of important canal construction just now. Boston has an important canal enterprise nearing completion after two hundred years of agitation. Mr. August Belmont, president of the Boston & Cape Cod Canal Company and American representative of the Rothschilds, a few days ago entertained a party of a hundred guests, including prominent public men and engineers from Germany, Russia, The Netherlands, and Canada, by taking them to view the canal being cut between the deep waters of Cape Cod and Buzzard's Bays, shortening the New York route. Nearly two-thirds of the Cape Cod canal has been completed, and the work should be opened to the public about the same time as the Panama canal. As all those interested in canal sight-seeing will want to view the work done before the water has been turned on, both the Panama and Cape Cod canals may be expected to attract thousands of visitors this year and next.

POLITICS occupy such a large share of the public attention that matters of finance, and especially mining finance, do not just now get much of a hearing. One day last week despatches were printed in all of the New York morning papers to the effect that the town of Cobalt was being wiped out by fire. Later despatches limited the damage to \$150,000, but in the meantime not a trader attempted to make any market capital out of the incident. Not so very long ago any similar event would have furnished a basis for speculation in thousands of shares of stock. Another instance of similar import was the cut-

ting of the dividend by the Goldfield Consolidated. It had long been anticipated that the extra dividend of 20 cents per share that had been paid each quarter would be dropped, and formerly there was always an accelerated movement in the stock just before the date of the declaration. Last week when the regular dividend only was declared, there was hardly any comment made concerning the action of the board nor any general discussion concerning the property and its further possibilities.

STATISTICS of accidents in metal mines are neither so common nor complete as in the case of coal mines. In the latter the occasional great explosion with the resulting death of a hundred or more men at once, long since attracted popular attention to the dangers of mining at the same time that it distorted the public view. The chief danger in coal mines as in others, is not that arising from gas or dust explosions, terrible as they are, but the ever-present danger of minor falls of rock. The majority of the miners killed in coal mines lose their lives because of falls of roof. In metal mines the same danger is present, and it would seem likely that an even larger portion of the deaths would be traceable to this cause. A list recently published records all the deaths from accidents in the mines of Clear Creek county, Colorado, beginning with 1863. The total is 176; not a remarkably large figure when the number of miners and number of years involved, is taken into account. The causes of the deaths may be summarized as follows: misfires, 21; explosions and premature blasts, 40; rock falls and caves, 60; suffocation, 5; miscellaneous, 50. Here it happens that death from accidents due to powder has come to about the same number of men as were killed by rock falls. The miscellaneous causes included such widely varied items as falling down a shaft, fall from a bucket, flood, falling timbers, and electrocution.

Funds for the Bureau of Mines

Congress is now busy with appropriation bills, always a sign of impending adjournment. The Sundry Civil bill as reported to the House fails to make any provision of funds for extending the work of the Bureau of Mines so as to cover metal mining in the West. As the matter now stands, except for a small sum available for administration and general expenses of the Bureau, all the appropriations are for the purpose of analysing and testing coal for the Government itself, mine rescue work in the coal mines, and the study of accidents, mainly in coal mines. The House passed, by a nearly unanimous vote, the newly drafted organic act which makes clear the purpose of extending the investigations of the Bureau to cover all branches of mining, but it has failed to furnish money to the Bureau proportionate to the scope of its work. The Secretary of Interior, Mr. Walter Fisher, has, in response to a Senate resolution, written a strong letter urging that \$100,000 be devoted to "inquiries and investigations into the mining and treatment of ores and mineral substances, and for equipment, supplies, travel, and other expenses incident thereto." It is hoped that this increase will be voted on the floor of the House. There will be general disappointment in the West if some provision be not made for work in the metal mines. Problems relating to fire, dust, and caving ground make investigations relating to the health and safety of the men as pertinent as in the Eastern coal mines. With the limited sum available the active director, Mr. J. A. Holmes, has occasionally sent the rescue cars into the metal-mining districts to demonstrate the new methods of fighting fire and giving first aid treatment. A much wider campaign of education is needed. The limited studies of health conditions in Colorado mines made by an officer detailed from the Marine Hospital service have been enough

to indicate that here is a wide field for usefulness. In the investigation of smelter-fume troubles the mining industry certainly deserves the aid of the Government quite as much as the farmers. Throughout the field mineral waste is a subject second only in importance to problems of the health and safety of the men. The United States has spent from the proceeds of the sale of government land, \$65,000,000 on reclamation work. This is a far-seeing and wise policy which has amply justified itself. During the period in which reclamation work has been under way \$7,000,000 has been realized from the sale of mineral lands. Why should not this sum, or some reasonable part of it, be spent to stimulate and protect the great primal industry of the West?

The Copper Situation

Statistics of the American Copper Producers' Association, presented on another page, indicate another reduction of surplus to the amount of 15,450,386 pounds. This resulted, not through any lessened decrease in production, which was in fact a trifle greater than for March or April, but because of increased domestic consumption and exports. The price of the metal continues to climb, and there is much speculation as to the soundness of the apparent demand. It is to be remembered that buyers seldom stock up till convinced that prices are to rise and that they usually come into the market with a rush. At the same time there is widely current a feeling that a tremendous deal is being worked out. The press agent's work is being handled most admirably, the only possible criticism being a tendency to overwhelm with denials when discrepancies are pointed out. The world's surplus has disappeared, but there is something of a mystery as to just where it went, in the face of record production that is not a matter for boasting just at this time. It is indirectly admitted, or stated upon apparently good authority, that the operating pool of producers which took the market in hand last fall bought 50,000,000 pounds of copper. It is only natural to ask: Was this all that was purchased, where is it, has it been sold, is it taken into account in the monthly figures given out, is it in dead storage? Copper prices are going up; spot is quoted at 17¼ cents, but this very fact may mean a pinch for the operators. The real question is, have the operators or the pool been able to market any of the metal which they have accumulated? It is not a particularly hard matter for one with a long purse to engineer a rise in the price of a commodity or a stock; the real work comes in unloading the accumulation at a profit. In broker's parlance, these operations, which go hand in hand, are known as 'running a corner,' which is not primarily such a difficult matter, and 'burying the corpse'; it is in the unsuccessful attempt to accomplish the latter that market manipulators most often come to grief. There is no thought of any financial disaster overtaking the men who are at the moment behind the movement in copper, but the fact remains that mine output is increasing and likely in the next few months to further increase largely, and it would seem to be a not unsafe prophecy that if the copper situation is to be kept in hand, another season of curtailment will become necessary. It is quite true that producers are stating publicly that increased production will be a boon, that otherwise the price cannot be held down and a 'runaway' market will ensue. The manipulator of a corner can never let the market take care of itself; if he cannot sell, he must buy; the moment he fails to maintain the price, his corner crumbles. There may or may not be any corner in copper; every copper authority is up in arms proclaiming loudly that there is not; but there are signs that would justify some activity

by bear operators—at least a 'feeling out' of the situation—were it not for the practically invincible financial strength of the men now in control.

The gist of the whole matter is very well summed up in a paragraph in an interview given by an authority on copper in New York: "Some surprise has been expressed that the copper shares have not responded more to the five-cent rise in the price of the metal during the past eight months. The answer is simple: there never was so much doubt as to the genuineness of a movement in copper as there is concerning the present one. When the public realizes that copper-share earnings are going to be very handsome during the next few years, stock-market quotations will commence more thoroughly to discount them than they have yet done." If the public would only come in and buy copper shares in large quantities, it would show a handsome profit on the entire operation, and losses taken in the metal could be considered negligible. Amalgamated is climbing for a high mark; it sold last week at 87½, which is higher than at any time since late in 1909. Dividends are being increased in some instances, and resumption is talked of in other cases, and while speculation in the metal is deprecated, investment in copper shares is encouraged in every way possible. In the meantime, as our New York correspondent shows, the large copper producers are rapidly increasing their outputs. Fundamentally the matter resolves itself into a question of the rate at which new production will follow the increased price.

Bolivian Goldfields

Bolivia has been much in the public eye this spring because of reported discoveries of placer gold, especially in the Tipuani district. A number of prospectors have gone down from San Francisco and in response to numerous requests for information, Mr. Carlos Sanjines, the Bolivian Consul, wrote a general description of the country and routes of travel to it, which we published on March 9. Washington despatches have recently stated that accounts of the discovery in the Tipuani valley were based upon misleading information and that the influx of American prospectors was likely to lead to serious distress. The Bolivian Government has risen to the occasion and is assisting the prospectors to go to other districts in which there are good chances of success. In the Tipuani valley there are numerous placers and much gold has been won, but the land is in private ownership and the difficulties to be overcome are severe. Bolivia, however, is a large country, and gold is widely distributed. The Dirección General de Estadística y Estudios Geográficos has recently issued a general monograph on the mineral industry of Bolivia, written by Sr. Pedro Aniceto Blanco. For those who read Spanish this is the best guide to the country, and to all the mining map accompanying the text will prove valuable. In studying the region it should not be forgotten that ancient records are far from accurate, and that in writing a general report such as this, no mining engineer could do more than sift and compile. It is not to be expected that placers examined and sampled as they would be by a mining engineer with ample time and assistance, await the staking. At the same time, a California prospector who worked in the country last year and returned to the United States this spring, found sufficient encouragement to warrant his return with reinforcements. In every rush, statements emanating from the district must be heavily discounted, and to go to any foreign country a prospector must have adequate financial backing, but with these provisos, the Bolivian field seems decidedly worthy of investigation.

Mining and Civilization

JAMES RALPH FINLAY

*On the night of April 14, of this year, the greatest steamship in the world struck an iceberg and foundered, causing the death of 1600 persons and shocking the civilized world. The serious comments of the press, outside of the mere news, centred mainly upon the thought that the accident was a case of failure in man's struggle with the forces of nature. It was so indeed in one sense; but the cause of the disaster was not really inability to master the forces which sent the ship to the bottom. It is not fault finding to say that the cause of the accident lay in human psychology. The men who ran the ship believed the *Titanic* to be unsinkable. Even after she struck, the passengers felt such confidence in her that many thought the getting into life boats was merely a disagreeable tribute to be paid to a sense of caution among the officers.

The salient fact of the whole affair is that a human mastery over some of the forces of nature is now generally taken for granted. To get a point of view, think of the adventures of Robinson Crusoe. On every voyage that hero either met or saw shipwreck. Robinson Crusoe is of course fiction but is better than a mere narration of facts to show what the people of that day thought and felt. In our day we have no more doubt of a good ship weathering a windstorm than we have of being able to read the morning newspaper. The *Titanic* disaster no more shakes our faith in successful navigation than a kick from a mule would disturb our faith in agriculture.

I suppose the three great steps in the progress of the human race to be or to have been the following: (1) The conquest and domestication of animals and plants; (2) the subjugation of weak and disorderly men by organized government, thus permitting the intelligent to pursue their chosen activities without the burden of incessantly defending themselves, and to travel and find out about the whole earth; (3) conquering the elemental forces of nature.

We are just taking the third step now. All our great achievements lie in that one province. In prehistoric times people could ride horses and take care of herds as well as we can today. In the time of the Romans the science of government and jurisprudence was advanced practically to where it is now, and many of the arts which government permitted and lack of government hindered, such as literature, sculpture, and architecture, were likewise developed as well as they are today.

What we have recently done, and are doing still, are things like mastering the properties of light which have given us the telescope, the microscope, and the spectroscope, thus opening up fields of information which would have made the Romans gasp with astonishment. Conquest along this line has shown us something of our place in the universe in a detail inconceivable to our predecessors. It has shown us both how little and how big we are. On the one hand, we can realize that the earth we live on, compared with the rest of the universe, is like a grain of sand to the Sahara, or a drop of water to the ocean; on the other hand, we know of organisms so small that billions live in a glass of liquid. Similarly, we have explored into the properties of heat, energy, and chemical reactions, opening up thereby another world of information. We have explored into the manifestations of life and into its history on this earth. All these conquests are quite new, and the really effective imagination of our generation is employed in them. Here is the special realm of modern thought.

The most evident thing about these great achievements is the effect, not the cause. Scientific understanding of natural forces underlies a prodigious expansion of industry and wealth. What does that wealth consist of? In the main it consists of marvelously improved vehicles of communication and travel, telephones, telegraphs, railroads, automobiles, elevators, and steamships; of comfortable and

safe abodes built, perhaps, of steel and concrete; of innumerable factories capable of supplying nearly every luxury or utility we can think of. This describes it inadequately. Our wealth consists of our ability so to use the natural elements of light, heat, gravity, and chemical reactions that each man no longer has at his service merely the muscular effort of his own body, and of the bodies of horses and cattle; but such great forces that with their aid one man may do what formerly required ten or twenty men to do.

I wish to draw your attention to the fact that practically all the means for these accomplishments are supplied by our mines. We dig out of the earth not only our materials but our energy. The modern ship is as good an example as any. She is wholly built of and propelled by the products of mines. The energy which makes possible the very process of building is supplied by mines, for almost every lathe and riveter in the world is driven by steam which is furnished by coal.

How shallow, then, is the idea so often entertained, and so casually expressed, that the business of mining is a kind of gambling from which the prudent business man should carefully shy away! On the contrary, mining is the main-spring of our whole industrial system! This, I think, must be so plain to every thinking man, that I shall not dwell on it further.

What I wish to inquire into is how far has this particular effort of civilization been accomplished? Have we gone nearly as far as we shall ever go in finding uses for minerals? Or is there still a vast field for expansion ahead? It is too big a question to be more than partly answered. It is plain enough that the expansion is still in full progress and that it is too big a movement to be stopped suddenly. This can be easily ascertained by the most casual inquiry into the facts. But it is a different and more difficult question when we come to look at it in its larger aspects. A parallel example may be found in the growth of cities and populations. Statistics show a rapid and undiminished rate of growth for our largest cities. A chart prepared by a distinguished engineer to show the probable growth of New York City, using all available indications for the serious purpose of laying out the city transportation lines, shows that by 1950 that centre will have a population of 19,250,000 within its present limits. Personally, I do not believe it, yet there is of course no visible evidence to the contrary. The only way to provide oneself with a good reason to doubt such calculations is to carry them on until they reach an absurdity. Why stop at 1950? The same growth might continue until the year 2000. If so, New York would be provided with a population of over 100,000,000. We may all be sure that there will be no such city. If our reason does not tell us so, our common sense does.

Similarly we must expect some limit to the increasing use of minerals. The main cause for increase is the rising consumption per capita in the great industrial nations. In 1850 each person in the United States used 1028 lb. of coal and about 75 lb. of iron; in 1910 each person used 11,000 lb. of coal and 600 lb. of iron. Now this enormous increase of consumption has taken place since a date when the age of steam and iron was already well started. Even in 1860, steamships went regularly between the principal parts of the world, railroads already connected the principal cities, and steam engines were driving the principal factories. Yet in the fifty following years the use of coal increased ten-fold. We have added in that time electric lighting, electric railroads, steel buildings, cement pavements, power elevators, automobiles, power-driven farm machinery, ocean cables, wireless telegraphs, and innumerable other avenues for the consumption of metals and of power.

If such an expansion is to continue for another fifty years we shall be using minerals with a lavishness that staggers the imagination. If it does continue, then each person will use 120,000 lb. of coal and 5000 lb. of iron every year, with other things in proportion. Allowing for the increase of population, such figures would mean a consumption of 10,000,000,000 tons of coal and 400,000,000 or 500,000,000 tons of iron annually in the United States alone. This

*Annual commencement address, Missouri School of Mines, May 31, 1912.

seems incredible and utterly out of the question. In other words, I believe that the enormous expansion in the use of minerals will soon begin to slacken. But I said a little while ago that there is no present evidence of slackening, so that it is necessary to explain.

My idea is that approximately the same causes which are producing the general increase of population, and particularly the growth of enormous cities, are behind the great expansion in the use of minerals. The cities grow because transportation is easy and quick; the largest cities grow especially because the perfection of communication allows certain forms of business which otherwise might be scattered all over the country to be carried on to best advantage in the largest city. New York, for instance, is growing on a multiplicity of small manufactures. Forty-odd per cent in number of the new manufacturing enterprises of the country are situated there, but the average number of employees is only 24. Undoubtedly this goes on because a great centre of population supplies artisans for each specialty, and because the city itself is the greatest single market. The highly improved transportation facilities naturally act to better advantage in carrying articles from big markets to lesser ones, than from lesser markets to big ones, for a variety of reasons that will occur to everyone.

The general increase of population is without doubt due to the same causes. This increase is taking place only in the great industrial nations or in regions controlled by them. The improvements in the means of getting a living, the cessation of useless wars and disorders, the reduction of plagues and famines have all been caused by improvements in transportation and production. These agents have afforded populations which had been brought to a standstill by restricted living conditions another chance to grow.

But in the centre of the world's civilization we find a great nation where the population is not increasing. I mean in France. The census figures show a marked decline in the birth rate also in the United States, and I believe the same facts are beginning to appear in England. I am not going into a discussion of race suicide. I am merely giving these evidences of a change in the swing of events. An enormous and continued increase of population is, I think, generally taken for granted. As a general fact it cannot be disputed, but its unlimited continuance is a manifest absurdity, for a few centuries of increase like that of the past fifty years would multiply the human race until there would not be standing room. A check is inevitable, and I believe it is already perceptible.

Similarly, we can find reason to expect a check in the growth of cities. This will come from the working out of the present cycle of industrial development. Whenever the perfection of transportation shall have brought all the people to the great cities who can profitably go to them in the pursuit of business or pleasure, the disproportionate growth of those cities will cease. Our greatest cities are already becoming so crowded and so excited that many people who once found them pleasant would be glad to leave them.

My idea is that the most highly civilized, or at least most active industrial nations may be already somewhere near their maximum productivity, although they certainly have not reached it. There are forces in action now which are plainly still adding to the industrial activity of the average man. While I do not pretend to have any special knowledge of mechanical matters, I take no risk in stating that not one of the great systems of power utilization has reached its full development. I mean that a given million people is not yet fully supplied with electric lights, telephones, automobiles, and other comforts and luxuries. To illustrate this I will give one or two specific examples. A classmate of mine is connected with the Boston Edison Electric Co. He told me that in 1896 that company had a total of 200,000 lights on its circuit. In 1908 they were adding lights within the same territory at the rate of 200,000 each year and expected to continue doing so for many years to come. Just think of that! Each year they are adding as many as were added in the whole 20 years after the business began, and that in the most mature city in the country.

The practical gas-engine is barely 20 years old, but in that short time it has revolutionized certain forms of industry and is rapidly revolutionizing, through the automobile, what we may conveniently call neighborhood transportation. It has also made real a dream of many ages, the navigation of the air. But it occurs to me that any specific thing accomplished by the gas-engine is of minor consequence compared with the fact that through it high-class machinery has become a plaything. It seems to me this may indicate that with us at least the great cycle of industrial development may be approaching its culmination. Let us dwell on this idea for a moment.

Water-wheels have supplied industrial power for thousands of years, but because no means had been invented for transmitting that power that form of machinery was chained down to certain localities. The invention of electric transmission removed that shortcoming and the power from water-wheels is rapidly becoming more usable. But, generally speaking, the manipulation of electric machinery remains in the hands of the specialist; and certainly up to the present the mass of the people have not been accustomed to use machines driven by water-power. The steam-engine has been in use for about 125 years. Its usefulness has been and is stupendous; but the necessity of providing with each unit a cumbersome boiler has always confined its use to trained specialists. Very few of us have ever tried to run any kind of a steam engine. To be sure the use of both steam and electricity has been gaining ground ever since they were made practical, but, after all, it remained for the gas-engine to bring high-class machinery into the hands of the average man. We may say that the age has arrived when it is as customary for the every day citizen to drive an automobile or operate a pump as it has always been to drive a horse. There is an enormous significance in this fact. Heretofore industrial efficiency has been growing because the use of machinery has been spreading from one class of people to another and from one industry to another. It has been growing because it could spread. When the use becomes universal there will be no such chance to spread. I am inclined to think, therefore, that we are within hailing distance of the time when the highly civilized and creative nations will have put as many power-using devices into the hands of their citizens as they can use. Now, since the principal use of minerals is to provide the means of utilizing power, I argue that the consumption of minerals will reach its maximum per capita amount at the same time.

In order to be understood, I will state the case in concrete form. Every person in the United States uses 600 lb. of iron each year, and uses more each year. I would not like to state a figure of how much each person will ultimately use, for that would be mere guesswork; but we may be sure that the amount will increase at least as long as the percentage of people who run automobiles increases. Since that point ought to be reached in a decade or two, I argue that each person will increase his consumption of iron for that long, but not much longer. For curiosity, let us see what this will mean to the steel business. In 1900 each person used 400 lb.; in 1910, 600 lb. At this percentage rate, by 1920 each person would be using 900 lb.; but suppose that the present decade is the culmination of the great power-using cycle, that the percentage rate will not be maintained and that the amount of iron used by each person increases only by the same number of pounds as during the last decade. We should by this calculation allow 800 lb. per person in 1920. The population of the country by that time should be 110,000,000. The amount of iron manufactured by that time should be about 44,000,000 tons, against 26,000,000 in 1910. Allowing that during the following decade the consumption would increase only 100 lb. further per capita and allowing for the increase of population, the output in 1930 would be 60,000,000 tons.

I am called a crank on statistics and I must try to avoid making myself tiresome. What I am driving at is to put before you some ideas about the prospects of the mining business. One question for a young man to consider is what hopes to entertain. There is no use going into a form

of activity which you do not believe in. I have used the figures just stated because I believe that they give a fair idea of the growth which may be expected in the mining business in the immediate future. It is perfectly fair, even conservative, to expect that the consumption of all mining products will double inside of twenty years. I have had in mind thus far the progress of our country only; let us consider the rest of the world a little.

The active industrial nations constitute today only a fifth, or perhaps a quarter of the human race. We may specify only Great Britain and her English-speaking possessions, Germany, Austria, Italy, France, Norway, Sweden, the Netherlands, and the United States as the really active industrial nations. The rest of the world is not altogether without knowledge of power-driven industry, but its knowledge as yet is only borrowed and its application sporadic. If the whole race used iron as fast as the people of this country the annual consumption of the world would be at least seven times what it actually is. Now I conceive that the industrial ideas of Europe and America are sure to be adopted in some form or other by all other peoples until they become universal, just as agriculture in earlier times must have spread from some source until it became universal. One would be bold indeed to say when all this will be accomplished, for nations and races have an obstinate way of working out their own destinies in their own way, but the events of the past few years contain many striking signs of the stirring up of intellectual life in Asia. The most conservative nations of the world, China and Persia, have broken with the traditions of ages and have not only undertaken to create republics, but China at least has succeeded in its establishment. Turkey and India have shown in different ways a capacity and desire for advancement. In India, for instance, a large steel plant has been started with native capital.

When we come to that word capital we reach one of the stumbling blocks of those nations that are industrially backward. According to many of our advanced labor unionists, capital and capitalism are the source of grievous economic injustices. Perhaps that is true, but whatever evils lie in the existence and domination of capital are surely counterbalanced by benefits that cannot exist without capital. I have lived in countries where there was little or no capital. There was likewise little or no industry, and little or no security, little or no labor, and mighty low wages. Capital is the symptom and the product of good morals, good government, and fair dealing, as well as of energy and natural resources. It cannot exist without general confidence in the integrity and ability of other people. Modern industry is most emphatically co-operative. The business or the enterprise owned by an individual is now a rare thing. The industrial unit is now the corporation, and that is created only by joint action and joint capital. People who are afraid to trust each other cannot form corporations and cannot participate very much in the best efforts of modern civilization. The progress of industry, therefore, in some countries may have to wait until the people prepare themselves for owning capital.

But at any rate there is an immense field for the further development of industry throughout the world. It is a fair presumption that the nations that are ahead now will continue to be ahead for some time. Undoubtedly they will find considerable business in furnishing the backward nations the facilities for making a start. The position of mining with reference to the development of civilization and of industry has been steadily growing and must continue to grow. In our own country we may be somewhere near the point where we have as much mineral wealth per capita as we can find use for, but in the world at large that point is still far off.

FORMOSAN mining statistics for the year 1911 are given in a consular report as follows: Number of mines: gold, 9; gold-copper, 1; gold dust, 27; copper, 2; mercury, 1; coal, 270; petroleum, 39; sulphur, 16. Production: gold, \$1,065,400; gold dust, \$48,882; silver, \$32,525; copper, \$264,513; coal, \$468,317; petroleum, \$3243; sulphur, \$22,950.

The Bradley Process

*The plant of the Copper Extraction Co., built near the Washoe plant of the Anaconda Copper Mining Co. by A. C. Burrage and others for the operation of the Bradley process in the extraction of copper, gold, and silver from the slime of the Washoe concentrator, is in operation, but is not yet up to what was expected of it, although it may yet be considered in the experimental stage. However, those who are closely watching the plant claim that it is only a question of time when the process will be giving every satisfaction. The plant was erected at a cost of nearly \$300,000 and has a capacity of 250 tons of material per day, part of the plant being capable of handling 500 tons per day.

In the operation of the process the ore is subjected to a carefully conducted roasting operation in what is known as an 'amphidizer,' the copper in the ore being roasted to a sulphate and most of the iron converted into ferric oxide. The finely crushed ore is heated in the amphidizer, which is a rotating furnace, to a temperature of between 450 and 550°C., air being blown in the amphidizer to accelerate oxidation. The roasted ore is next brought into contact with an excess of calcium chloride solution in a reaction drum, which is maintained at a temperature of about 100°C. Cupric chloride is produced by the reaction between copper sulphate and calcium chloride, while any ferric sulphate in the ore coming from the amphidizer reacts with calcium chloride to produce ferric chloride, which is soluble. The calcium sulphate resulting from both these reactions is insoluble and is separated by filtration in the succeeding step. The production of ferric chloride at this point is advantageous in that it dissolves any copper oxide, copper sulphate, or metallic copper which was unaffected in the amphidizer, producing copper chloride, and this ferric chloride also maintains the copper chloride in the cupric state. The gold and silver in the ore is brought into solution by making all the copper into cupric chloride and then adding a small amount of chlorine. The chlorides of silver and gold, being soluble in calcium chloride solutions, may afterward be precipitated with the copper and subsequently separated. After leaving the reaction drum the mass of gangue, solution, and precipitate is subjected to filtration. The solid matter forms a cake which consists of the gangue, except a small amount of iron and alumina which have been taken into solution, and the calcium sulphate precipitate already mentioned. The solution contains the dissolved copper, a small amount of iron and alumina, and any zinc which may have been in the ore; the arsenic will have been separated by filtration, as it has been rendered insoluble.

The solution is then in condition for treatment for separation of the dissolved metals. The precipitation of iron and alumina may be made by cupric oxide, or milk of lime, and as this precipitate will carry some copper, it is returned to the amphidizer. In the amphidizer the iron and alumina in the precipitate are rendered insoluble, while the copper is left in a soluble condition and can be recovered. The solution from which the iron and alumina have been removed is run to a second tank in which the copper is precipitated by lime as oxide of copper. This precipitate is filtered from the solution and the copper is recovered.

The zinc contained in the ore passes into the solution as chloride of zinc. It is therefore necessary at stated times to run the solution or part of it, after the final treatment and before returning it to the reaction drum, to a third precipitator in which the zinc is precipitated by means of lime. Then the regenerated solution, from which the gangue and all metallic compounds have been removed and which contains calcium chloride, is returned to the reaction drum for the treatment of additional ore from the amphidizer, thus completing the cycle. There are over one million tons of slime stored up near the Washoe smelter, and it is increasing, though the company is handling some of the material by briquetting it and treating it in the blast-furnaces. The slime carries about 2¼% copper and about \$1 per ton gold and silver.

*Abstract from the *Boston Commercial*.

The Three Giant Producers on the Rand in 1911

By ROWLAND GASCOYNE

A good deal of attention in one way and another has been attracted during the year to the doings of the three giant gold producers of the Rand, and it may not be amiss to compare their results in a short article. Each of these giants has in turn, during the year, in different months, occupied the proud position of the biggest gold producer in the world, when based on their monthly outputs, but it seems doubtful to which of the two leading producers that position will ultimately fall. The Randfontein Mines has held that position for the past six months and has still 350 stamps in reserve, while the Crown Mines has just completed a new mill of 160 stamps and crushes higher grade ore than Randfontein, so that it is

Perhaps the most remarkable feature of the above table is the exceedingly narrow margin in the total value of gold recovered separating the three companies, but it ought in fairness to be pointed out that the Randfontein did not start its mammoth mill of 600 stamps until Mareb. It will be noticed that with the exception of the total tonnage crushed, the Crown Mines is ahead of its two near competitors in its gold output, costs, and profits. Naturally its higher output of gold and profits are due to the better grade of the ore and high extraction. The consulting engineer explains that the working costs of the year are high on account of capital expenditures incurred during the year. It is difficult in the absence of

CASON G. M. CO., EAST RAND PROPRIETARY MINES.

by no means a foregone conclusion as to which of these two concerns will hold the coveted position in the immediate future. The East Rand Proprietary Mines can scarcely be expected to again aspire to first place in the face of the latent growing powers of the other two companies, but at all events, for many years to come, it should make a creditable third. Taking the total gold recovered during 1911 as the index to the position of the company, their relations will stand as shown:

	Crown Mines.	East Rand.	Randfontein.
Tons milled	1,618,500	2,194,552	2,159,033
Total value of yield....	£2,831,625	£2,784,882	£2,661,280
Value per ton.....	35s. 0d.	25s. 4½d.	24s. 7d.
Cost per ton.....	19s. 0d.	16s. 8½d.	16s. 8d.
Total profit	£1,271,106	£956,621	£849,241
Profit per ton.....	16s. 0d.	8s. 8d.	7s. 11d.

further explanation to understand why this is so, unless it is meant that these extensions require unskilled labor which otherwise would be used for revenue-producing purposes. At the East Rand Proprietary Mines it transpired that as soon as the extension ceased, the working costs advanced, because then the true position had to be faced. Standing charges could no longer be allocated to capital outlay, as is often done when capital outlay and revenue expenditure run side by side. At the Crown Mines it almost seems as though the reverse effect was claimed. It must be pointed out that generally on the Rand, as elsewhere, high costs usually accompany high-grade ore, but at the Crown Mines, ever since the consolidation and the huge capital expenditure was undertaken, working costs have been steadily rising above the average of the individual companies prior to the amalgamation. When, however, the main 13th level is finished throughout the property, the hoisting and haulage arrangements completed,

and the underground and surface operations concentrated, a material reduction in the working costs is expected.

It is difficult to realize the huge scale upon which the Crown Mines will be ultimately worked. It is an amalgamation of half a dozen mines, stretching three miles from east to west, and has, in addition, such a considerable area to the dip, proved and unproved, that the resources are impossible to estimate with any degree of accuracy. Its milling equipment consists of 835 stamps; a new mill of 160 stamps having been recently erected. The profitable ore reserve at the end of the year stood at 10,124,072 tons, of an average assay value of 7.25 dwt. over 62½ in. There were seven main hoisting shafts on the property at one time, but these are being reduced to two; No. 5 with an equipment capable of hoisting 6000 tons per day of single shift, and No. 7, equipped for an output of 5000 tons. These shafts are connected with the different mills by an elaborate system of electric railways. The construction program and extension will probably be finished soon after the middle of the current year, and huge as the ore reserves are, they are none too great when once the hoisting and milling equipment gets into full swing. When compared with the previous year the average working costs show an increase of 1s. 2d. per ton, an increase which the general manager attributes to closer sorting, higher charge for development and sand-filling, and not to the influence of capital outlays as maintained above.

With regard to the East Rand Proprietary Mines, it is difficult to know what to say, as so much has been said regarding the affairs of this concern during the past six months. If the figures shown above are reliable—and they are as trustworthy as the staff can compile—they show a remarkable similarity to the Randfontein figures for 1911 in tonnage milled, grade of ore, costs, profits, and even in the profitable ore reserve. The superintending engineer has made a report on the year and shows that 820 stamps were at work, crushing 2,194,552 tons, representing a duty per stamp per 24 hr. of 8.23 tons, a screen value per ton of 6.579 dwt., and a yield of 6.054 dwt. The actual extraction is quoted as 83.9%. The cost of mining is given at 8s. 3.7d.; development, 3s. 1.5d.; reduction expenses, 4s. 8.8d.; general expenses at mine and head offices, 5.9d.; total working cost for 1911 equalling 16s. 7.9d. per ton, as compared with 15s. 6.4d. in 1910. The working costs have somewhat increased per ton of late, owing to a revision of figures of tonnage treated and the stopping of development and capital outlay, thus throwing all the cost upon revenue. The general superintendent points out "that the method previously adopted by the management to secure cheap tonnage by milling rock of low grade is being changed for a policy of eliminating as far as possible from mining operations all ore of an unprofitable grade. This will tend to restrict tonnage and increase working costs, and must ultimately result in increased profits to the company." There can be no two opinions about the general soundness of this new policy, but on the Rand low-grade ore has sometimes to be mined to get at that of a higher and profitable grade, while the raising of costs at the East Rand has thrown 4,000,000 tons out of the profitable ore reserve and also materially increased the cost per ton. There are so many million tons of ore near the profit limit in the East Rand that the mines are not all suited to what is known here as the policy of selective mining. The ore of high grade is limited, and the salvation of the East Rand would seem to be low tonnage-costs coupled with wholesale mining and close sorting. As a proof of this assertion, it may be pointed out that whereas, under the present inflated working costs, the profitable ore reserve on December 31 last was estimated at 6,716,605 tons of an assay value of 6.9 dwt., over a stopping width of 55 in., there is another 11,000,000 tons of lower grade, one-half of which would be profitable were working costs brought down to a reasonable level. In estimating the profitable ore reserve, the superintending engineer raised the profit limit from 3.1 dwt. to 4.3 dwt., whereas at Randfontein, with almost

the same grade of ore and working costs, the profit limit of some of the ore reserves is taken as low as 2.832. While it is generally recognized that all the trouble at the East Rand during the year was due to inept management, its effects have been somewhat exaggerated, and advantage has been taken by the new management of the old position to make the future more easily adapt itself to their estimates.

The Randfontein Mines, although the least in area of the three properties considered, owns over 2600 English acres. During the year 745 stamps were at work, and it is expected that the present year will enable the others to be started, thus bringing the total number of stamps up to a thousand. The estimated ore reserve at the end of the year was taken at 6,637,271 tons, of an average assay value of 6.6 dwt., of which 5,658,859 tons assayed 7.29 dwt., the remainder assaying only 2.8 dwt. per ton. As an instance of the amount of development carried out during the year, the footage totaled 87,541 ft., of which 1747 ft. represented shaft-sinking. Despite this large amount of work, the property as yet is far from being excessively developed. The Randfontein is a compact self-contained property, possesses its own power-station, and seems likely to continue to make a strong bid for the position of premier gold producer of the world; a position, be it noted, it has already held for the past six months.

It may be interesting to notice that these three concerns produced practically a fourth of the whole of the gold output of the Rand last year, although the Randfontein did not start its huge mill until March of that year. These large Rand mergers were expected to materially reduce the costs of working, and especially of administration. At the Crown Mines the costs have gone up by several shillings per ton. The following figures speak for themselves on this matter:

COSTS OF WORKING PER TON MILLED

	Crown Mines.	Randfontein.	East Rand Proprietary.
Mining and development.	13s. 0d.	12s. 0d.	11s. 5¼d.
Ore treatment	4s. 3d.	4s. 3d.	4s. 8¾d.
General mine and office..	1s. 9d.	0s. 6d.	0s. 6d.
Total	19s. 0d.	16s. 9d.	16s. 8d.

There can be no doubt, however, that when the whole of the milling plant at the Crown Mines gets to work, the new equipment finished, and the cost divided into a larger tonnage, the costs of administration per ton milled should witness a decline.

THE Crown Reserve M. Co. has become involved in some rather interesting litigation growing out of the transactions occurring when the company was organized. The properties were secured from a syndicate, to each of whom individually certain allotments of stock were made. In addition to the issue of stock to the individuals a block of 570,000 shares of stock was set apart to be used by the directors as working capital, and to be disposed of as might best advance the interests of the company. Out of this amount of stock 390 shares have been sold and the syndicate has now come into court to compel the conclusion of the trust, whereby these shares were held, and the distribution of the residue of 231,000 shares pro rata among the members of the original syndicate, the claim being made that the mine is fully developed and the reason for the original trust agreement no longer exists. The company denies the claim of the syndicate members to this stock, and also contends that the stock so put in trust should be held to meet the possible treasury needs of the company in the future, and that this is true, notwithstanding that just at present the Crown Reserve is in a flourishing condition. It will be somewhat interesting to have a judicial determination upon the point as to when a mining property is fully developed.

CANADIAN exports last year amounted to \$303,763,328. Breadstuffs and provisions are the principal items of export, but to the United States the chief exports are minerals and metals and wood for paper pulp.

Genesis of Silver-Lead Ores in Wardner District, Idaho—III

By OSCAR H. HERSHEY

(Concluded from page 786.)

ALHAMBRA TYPE

In the eighth system I place the Alhambra and Upper Cate faults, great reverse faults that resulted from a strong thrust from the southwest, a repetition of the conditions under which the fourth system was formed. It also includes the Gus fault. The displacement on the Alhambra fault is at least 3600 ft. The fault is accompanied in places by lenses of a peculiar, very fine-grained ore, consisting of finely-sheared quartzite cemented by quartz, siderite, pyrite, very fine-grained galena, and probably sphalerite. One lens is described as 60 ft. long and 6 in. to 3 ft. thick, and another 30 ft. long and 4 to 5 ft. thick. Assays have yielded as high as 30% lead; generally there is 1 oz. silver to each per cent lead. This type of ore is probably confined to the narrow zone of severe shearing accompanying the Alhambra fault.

BUNKER HILL TYPE

The most characteristic feature of the Bunker Hill mineralization is the scarcity of pyrite. The orebodies consist of a breccia of quartzite fragments cemented by siderite and galena, with a small number of white quartz seams, the latter often younger than the galena. Small quantities of chalcopyrite, tetrahedrite, and pyrite present may belong to earlier stages of mineralization; this certainly is true of the rare blende. The Bunker Hill type is genetically connected with the Upper Cate fault. It was the compressive stress that produced the Upper Cate thrust with a displacement of over 2700 ft. that gave rise to the ascending currents of water in this stage. The chief development is in the March ore-shoot. This is clearly and definitely related to several structural features. It occurs chiefly in the roughly triangular block of Upper Burke quartzite that is bounded by the Upper Cate, Sullivan, and Flint faults (the latter, in a faulted condition, extending to the Upper Cate). Its position in this block seems to have been controlled by the locus, on each level, of a certain brittle white quartzite; hence, it wanders about somewhat. It never passes below the Sullivan fault nor above the Upper Cate fault, but on certain levels extends a short distance below the Flint fault. The Lower Cate fault has cut through the ore and dragged some of it down to a lower position; on this account, on certain levels, the shoot is largely in the inter-Cate zone. It has been traced from the surface to Bunker Hill No. 12 level, a distance on the pitch of 3150 ft. It is the greatest ore-shoot in the Wardner district and has produced to date over 1,675,000 tons.

From a point below Bunker Hill No. 8 level to No. 12 level, an arm extending along the Key seam southeastward from the March shoot had produced about 248,000 tons up to June 1, 1910. Another Bunker Hill ore-shoot came to the surface in the Serafford open-cut; the original discovery of lead ore in the district was made on it. Before the Lower Cate faulting it was merely a north-west wing to the March shoot, with which it merges in depth. The total production has been about 378,000 tons. The Stenwinder shoot has probably produced 275,000 tons. The East Tyler is another Bunker Hill shoot. These three shoots I regard as due to branch currents which left the main March current and made their way up between the Upper Cate and Sullivan faults on much steeper courses. As they rose, the solutions spread and made larger ore-shoots. The total production of ore of Bunker Hill type has been over 2,584,000 tons. This is significant, in view of the fact that it represents the latest important ore mineralization in the district, a stage succeeding a complex series of faultings and associated mineralizations. Its ore-shoots converge in depth into a sort

of chimney whose site is controlled by the Flint fault because that is the line along which the block being up-thrust by the Upper Cate faulting dropped over the edge of hard quartzite on to more easily fractured Upper Burke quartzite. As far down as the structural relations remain the same, we can expect considerable Bunker Hill ore in this vicinity.

JACKASS TYPE

The Jackass, the only reverse fault in the ninth system, with a displacement of at least 3200 ft., has a breccia which, on the Jackass claim, has been largely cemented by seams, and pockets of quartz and limonite that yield

JACKASS FAULT.

(Photo by W. J. Elmendorf.)

a little lead and silver by assay. This is the latest lead mineralization, so far as I can see, in the district. It may have been derived from the bands of disseminated lead and zinc ore that come up under the Jackass fault in the vicinity. The great normal faults of the ninth system are the Osburn with a probable displacement of 10,000 ft., the New Era proper with a displacement of 5000 ft., and the Lower Cate with an apparent displacement of 800 ft., more or less. They cut the earlier faults and veins into fragments which they dragged so far apart that it is difficult to correlate them. Many faults of comparatively small throw belong to the system, including the Taylor, Howard, Omaha, Switchback, Nellie, Dull, Arizona, and Keating, but being post-mineral they are of no importance in this discussion. The age of the Tyler, Flint,

Kellogg, Presley, Schofield, Bee, Hornet, Sandow, Silver, Hoffman, Kirby, and Silver King faults is not known with sufficient definiteness to warrant giving them place in the nine systems, but some of them have played important parts in the mineralization of the district.

RELATIVE IMPORTANCE OF MINERALIZATIONS

In the early part of 1911 I estimated the production of the Blue Bird type in the district as over 2,515,000 tons, the Jersey type over 831,000 tons, and the Bunker Hill type over 2,584,000 tons, a total of over 5,930,000 tons of ore. In the future the Bunker Hill type will greatly predominate for a number of years, but if the Hatton, Roberts, and Fan shoots that have been sliced off at depth by the Upper Cate fault be picked up under the Lower Cate fault as I expect, the Blue Bird type will gradually regain its standing. The most notable change will be a great increase in the importance of the Jersey type.

GENERAL DISCUSSION

In the Coeur d'Alene district, three things have been necessary in the making of an orebody, namely, a source for the minerals, a fissure, and a cause for the movement of water along the fissure. F. L. Ransome³ argues that the ores have been derived from considerable depth and precipitated from ascending solutions that were hot and under high pressure. In the Wardner district the distribution of the lead mineralization in at least two stages, the Blue Bird and Bunker Hill, points distinctly to ascending solutions that spread out fanwise as they made their way up through the rocks. For instance, in the Motor system of orebodies, descending solutions would hardly have left the Phil Sheridan mineralization and become confined to small seams under that zone. A lateral movement of the water is out of the question on account of the many fault gouges that it would have to pass through. The occurrence of the ore in shoots that descend to great depths proves that, whatever may have been the initial direction of movement of the water, it was deflected by the faults to a parallel course, either up or down. Deposition from descending water would imply more or less 'secondary enrichment' in the sulphide zone, of which there is absolutely no evidence. Enriched ores due to the influence of proximity to the surface can be found locally in the district, but only in the zone of oxidation, and then only on the sites of the original veins. I have been surprised at the scarcity of lead in crevices of the rock north of the vein zone, the first mile of which must at one time have been overlain by the vein zone containing millions of tons of lead. One would expect the meteoric waters to carry more or less of this lead down into crevices of the underlying crushed quartzite, and it is a remarkable fact that almost nothing of the kind can be found. The Wardner sulphide ores extend unchanged to too great depths to be due to the secondary enrichment process. The Blue Bird type before the Cate faulting had a known vertical range of at least 3250 ft. Before the formation of such great faults as the Osburn and New Era, which are younger than practically all the ore in the Wardner mines, the bottom of the valley of the South Fork of the Coeur d'Alene river was at least as high in the strata as the top of Kellogg peak; in other words, Blue Bird and Jersey ores found on Bunker Hill No. 12 level were, at the time of their formation, at least 5800 ft. below the surface, far too low to be within reach of descending meteoric waters capable of depositing sulphides. Since the ore deposits on the south side of the Osburn fault were formed they have been dropped at least 8600 ft. by the Osburn fault, those south of the New Era fault at least 3200 ft. additional, and the orebodies of the inter-Cate zone at least 225 ft. additional, by the Lower Cate fault. Thus there is evidence that the range was originally over 13,000 ft. The ore in the Murphy stope on Bunker Hill No. 12 level must have been deposited at least 11,000 ft. higher than the ore on the main tunnel level of the

Senator Stewart mine. This ought to effectually dispose of all theories of the origin of the minerals involving descending solutions.

Mr. Ransome is disposed to regard the faulting of the Coeur d'Alene district as in some way related to the intrusion of the great quartz-monzonite batholith of central Idaho, whose northern extension he considers may underlie the district with a very irregular surface, permitting some of the higher points to appear at the present surface in small areas extending from Two Mile creek to beyond Prichard creek. It is true, as he argues, that after the monzonite masses, as we see them at the present surface, had solidified, the deeper portions of the magma may have remained fluid for a very long time and may have continued to disturb the overlying strata, but it seems to me unlikely that no dikes of monzonite would have penetrated along some of the faults to the present surface. My impression is that he did not attach sufficient importance to the wonderful complexity in the faulting of the district and how it may be generalized into distinct systems, due to forces of different nature and certainly representing a very long period of time. It seems to me unlikely that the magma continued to be active to as late a period as the formation of the Upper Cate fault. I have the same objection to his idea that the ores were formed by solutions that continued to emanate from the deeper portions of the magma long after the arms that reach the surface had solidified, namely, that the ascending solutions continued too long, as proved by the relation between the orebodies and the structure, to be reasonably referable to the action of the same magma. I attribute the disseminated zinc-lead mineralization in the Wardner district to magmatic waters expelled by the monzonite batholith, and I think the influence of the heat of the batholith may be seen in the Sullivan pyrite dissemination, but all the ore-making mineralization I believe to have originated in a different manner. Without any very important exception, the ores of the Wardner district are genetically connected with the reverse faults. One reason may be that normal faulting made stronger gouges than reverse faulting, and gouges were distinctly inimical to the deposition of mineral; but I think the principal reason is that the compressive stresses necessary to make great thrusts forced the waters universally present in the rocks at great depth to ascend to the surface. No magma is required, for the initial heat of the water, intensified by compression of the rocks, would satisfy the chemical requirements.

Mr. Ransome attributes the origin of the lead and zinc in the Coeur d'Alene district to the monzonite magma. He says: "Some of the sulphides were deposited at once in the contact zone simultaneously with the development of magnetite, pyroxene, garnet, biotite, and other contact minerals. * * * The greater part of the sulphide of lead and all the ferrous carbonate traveled farther through the fissured sediments and under suitable conditions of temperature and pressure attacked and replaced the quartzite rocks." Lack of space will not permit me to fully discuss this subject, but I want to say that I am seriously considering the idea that the source of much, if not all, of the lead and zinc in the district has been in a comparatively thin band near the top of the Prichard slate formation. They may have been precipitated with iron carbonate and pyrite at the time of the deposition of the fine carbonaceous mud that has been altered into the Prichard slate; or the metals may have been derived with the sediments from the land area. It is significant that the lead prospects in Prichard areas are all rather high in the formation. Sphalerite is usually a notable constituent. In the Canyon creek group of mines sphalerite seems to become more abundant as the monzonite area is approached and also as depth is attained, but both of these directions happen to coincide with the approach to the Prichard slate. Though not noticeable as yet in the Wardner mines, throughout the Coeur d'Alene district an increase in the sphalerite content of the ores is supposed to be a function of depth; this does not vitiate the statement that throughout the district sphalerite, as an important con-

³Professional Paper No. 62, U. S. Geol. Surv., 1908.

stituent of the commercial ores, is limited to a particular stratigraphic horizon, namely, near the top of the Prichard formation. It seems to me this must be more than a mere coincidence; also, that it is hardly compatible with the idea of a magmatic origin for the deposits. If the upper part of the Prichard were the gathering ground, deposition would not extensively occur until a higher horizon was reached, explaining why 99% of the lead has come from veins in the Burke and Revett formations. When the solutions started at the Prichard slate they were richly laden with the elements necessary to deposit sphalerite, but they lost the zinc faster than they did the lead. The disseminated zinc and lead deposits in the Wardner district are among the few examples of a high zinc ratio

PART OF IDAHO.

in mineral deposits in Revett quartzite. The waters were under such intense pressure and heat that they were able to carry much of the zinc higher than usual. It is to be noted that the Cataldo quartzite areas are notably barren of lead and zinc deposits, though doubtless also underlain by the monzonite batholith.

I do not consider the problem solved beyond any doubt, but I believe that Mr. Ransome's magmatic theory and my theory of the minute dissemination of lead and zinc in the upper portion of the Prichard slate and possibly some of the Lower Burke quartzite, exhaust the possibilities in so far as the Wardner district is concerned. We may, therefore, expect the lead, zinc, and associated silver to continue down to the Prichard formation, or until the sediments are cut off by the presumed monzonite batholith. Without a radical change in the structure with depth, the ore deposits may continue to an almost incredible depth. The great Blue Bird ore-shoots are, with depth, slowly advancing stratigraphically upward in the Lower Revett quartzite. The March ore-shoot, for a distance of 3150 ft. on the pitch, has nowhere departed far from one band of white quartzite near the top of the Upper Burke. The Jersey and 'N' veins are advancing to higher stratigraphic horizons with depth, and the Caledonia vein may remain in Upper Burke rocks to a very great depth. In short, the danger that menaces the mines of the Canyon Creek group, the danger of reaching the Prichard slate, need not be feared at all in the Wardner district. Through studies of the post-mineral faulting I have determined that the danger of the ore-shoots being cut off by the

monzonite at a depth attainable by mining is very remote. Furthermore, if my theory of the origin of the lead and zinc minerals be correct, the known disseminated lead and zinc deposits above the Buckeye fault are probably at least 11,000 ft. above their source, the latter being at least 8800 ft. deeper than Bunker Hill No. 12 level. The only apparent serious menace to mining in general lies in the tendency of the ore-shoots to converge with depth. However, I have no fear that the principal company operating in the district will not find commercial orebodies of no mean size at the depth of at least a mile below its present deepest level.

Briefly summarized, I favor the theory that the lead, silver, and zinc minerals of the Wardner district were originally disseminated through certain bands of the Belt sediments; were first concentrated into the visible disseminated zinc and lead deposits through the action of the heat and probably water emanating from a monzonite magma; and were then concentrated into commercial orebodies by hot waters that were forced to ascend by the compressive stresses that produced the thrust faults, these thrusts opening the fissures in connection with which the ores have been deposited. The ores of each successive stage have probably been derived in part from those of earlier ore-forming stages, in part from the visible disseminated deposits, and in part from the original minute disseminations in the sediments.

The Silver Market

There is a noticeable tendency among the followers of the metal markets in Eastern financial centres toward silver as a medium of speculation. The situation in copper is such that, while the market is looked upon as fundamentally sound, it is at the same time admitted to be in the hands of producers and held with so much strength as to overcome for a time the law of supply and demand. The markets in other metals are receiving more than their usual share of attention. Silver is higher now than it has been at any time during the past several years, and the situation in the Far East furnishes a basis for speculative action. The large loan that is to be made to the new Chinese Government is one of the features receiving attention, and if the negotiations are carried to a favorable conclusion the result will be a largely increased demand for silver. For some months the leaders in the market for silver bullion have been paying a great deal of attention to the condition of the treasury in India, and the approaching necessity of the Indian Government to resume the purchase of silver for coinage. In addition to the increase in demand from these sources tending to make for higher prices, there is liable to be some curtailment of output. The production from Cobalt is decreasing, rather than increasing, and may be expected to decline in a greater ratio as the various properties near the limit of production. The Mexican situation makes also for curtailment. The labor situation in Mexico is as bad as the political situation; in fact, the two are so intermingled that it is sometimes hard to tell which element predominates. There has been a great deal of discussion concerning the imports of gold into British India, and not a little emphasis has been laid upon the tendency of people in India to convert their savings into bullion, in a form that will admit of its being carried about on the person and the possibility of an enormous amount of yellow metal being withdrawn from the monetary supplies of the Western nations by this means. The most recent reports indicate, however, that there has been a lessening of the demand from India, but it is still considered by some of the best authorities a very important question when considering the industrial needs and the requirements for circulation by American and European countries.

VLADIVOSTOK is 7443 miles from London, and the distance can be covered by the Siberian railway route in 11 days. The trip from Peking to London is made in 12, but when the proposed cut-off from Kalgan to Khabarovsk is constructed the time will be reduced to 9½ days.

Small Concentrating Mills in the Wisconsin Zinc District

By W. F. BOERICKE

The economic conditions in a mining district will largely control the means used for concentrating the ore. Many of the small zinc mines of Wisconsin are worked on a small scale by lessees with limited capital, and milling methods are the outcome of experience. Lack of capital, as well as lack of the technical knowledge necessary to build and operate a mill of large capacity, have held back the lessees, and the mills, therefore, are of nearly uniform type: small, light, low in first cost, low in operating cost, and capable of being run successfully by ordinary labor. The fact, moreover, that the lessees do not actually own the land, and hence are obliged to pay a royalty to the owner, tends to make them wary of sinking a large amount of money into a plant that, once their mine plays out, is usually only so much junk. Leasing seldom makes for the best development of the mine, as the tendency is usually to look only for high-grade ore, and prospecting and working of low-grade ore is either neglected or minimized. In Wisconsin a mill of 50 to 75-ton capacity per 10-hour shift usually satisfies the operator.

The ore mined is mostly sphalerite, or 'jack,' as it is universally known, and occurs in a peculiar pitch and flat formation which I believe is unique. The geology of the field cannot be discussed here; an excellent description is given in Bull. 9 of the Wisconsin Geol. Nat. Hist. Surv., and Bull. 294 of the U. S. Geol. Surv. Along with the jack is found

for Wisconsin, as given by the United States Geological Survey, are below, in percentages:

	1909.	1910.
Total concentrate in crude ore.....	10.8	9.7
Lead	0.7	0.5
Zinc	10.1	9.2
Metallic content	4.3	3.6
Lead	0.5	0.4
Zinc	3.8	3.2
Average zinc content of sphalerite concentrate...	37.6	34.8
Average lead content of lead concentrate.....	79.3	78.7

It will be noted that the metallic content is considerably higher than that reported from Joplin, in both the soft and the sheet-ground. The lead is non-argentiferous, and the zinc is free from cadmium. Zinc concentrates usually carry a little lead, which the jigs are not able to clean entirely. No doubt were tables used generally in the district, a cleaner product would result, but they are rarely seen. A typical assay of the concentrate of a well known mine is:

	Per cent.
ZnS	61.6
FeS ₂	28.3
PbS	0.7
CaCO ₃	4.4

The remainder, 5.0%, includes silica, magnesium carbonate, and alumina, in varying amounts.

The ore occurs in the so-called galena limestone, a granular crystalline dolomite of varying hardness. In general, it

PRODUCTION OF LEAD AND ZINC IN WISCONSIN IN 1911, BY DISTRICTS, IN SHORT TONS.

closely associated considerable marcasite and calcite, or as the miners put it locally, 'sulphur and tiff.' Above the jack, in the so-called 'top flat,' is found 'dry bone' (smithsonite) and galena, which were extensively worked in the early days. It is, of course, the object of the millman to keep these products separate; a mixed concentrate of dry bone and jack being objectionable to the smelter. In some mines of the district this is nearly an impossibility, and this naturally interferes greatly with successful work. Fortunately, the 'jack' deposits are usually considerably below the 'bone,' and they can thus be mined separately.

The district, speaking generally, does not produce high-grade ore, nor does the mine-run rock, even after sorting, make a high-grade concentrate. Very few mines ship a product assaying more than 50% zinc. Even 40% is usually considered high grade, unless the ore has been roasted. Here at once is seen a striking difference between the Wisconsin field and Joplin, where 60% ore is the rule rather than the exception. The average of the Wisconsin field would probably be between 35 and 40%. The official figures

breaks clean from the mineral. This important point makes coarse crushing possible and reduces the sliming materially, as the rolls and crusher may be set wider. There is, of course, a maximum size where the limestone is not broken from the jack, but the usual tendency is to go to the other extreme, and crush finer than necessary, with heavy loss in slime. The marcasite and jack are often so closely associated that they are not separated by the rolls, but stay together as one piece, even in the finer sizes. This makes little difference, as, if the former is there, it will come out with the jack in any case on the jigs. Of course, if the ore is to be subsequently roasted, it is important that the two should be separate.

The mills are usually spoken of as having a capacity of so many tons per 10-hour shift—50, 75, or 100 tons. The figure is somewhat misleading. It is possible to crowd the ore through a mill so as to almost double a stated capacity, the limiting factor being where the loss in tailing exceeds the increased economies of operation, or to put it otherwise, where the loss of zinc per ton of tailing is greater

than the decrease in cost per ton of ore milled. The practical limit is a matter of experience, and must be decided by the operator. If the ore is rich—and by richness is meant high in percentage of concentrate in the ore, regardless of whether the concentrate be zinc or iron—a smaller tonnage can be put through than of an ore carrying only a low percentage of concentrate. The ideal ore from a milling standpoint is one in which the entire metallic content is a valuable mineral, but such an ore is rare in Wisconsin, where the marcasite and jack are so closely associated.

Speaking generally, the tendency in the field is to put too little rather than too much through the mill. Millmen usually have preconceived ideas of how much a mill can take, and to educate them out of the rut takes time. It is needless to remark that they invariably minimize a mill's capacity. Larger tonnage with the same crew—which should be the case—means more work and close attention all around—elimination of the little stops and hitches that hold up a mill, and in the total these amount to a surprising proportion of the shift. It is only natural that they prefer the easier course. For an operator who wants to increase the

should be a fairly good mechanic, able to make minor repairs and adjustments to the machinery, line-shafts, repair jigs, and, in short, he must keep the mill running. He must understand how to treat the ore and get the largest economical extraction. While the mill is in operation, he watches the jigs, sees that the beds are right, attends to drawing off the concentrate, and generally keeps a watchful eye on the entire operations. His helper does the heavy manual work—shoveling concentrate into the ear or barrow and working on repairs under his direction. The crusher-man works only on the rock-breaker. In one case I have seen him sort waste from the feed as it comes from the bin and throw

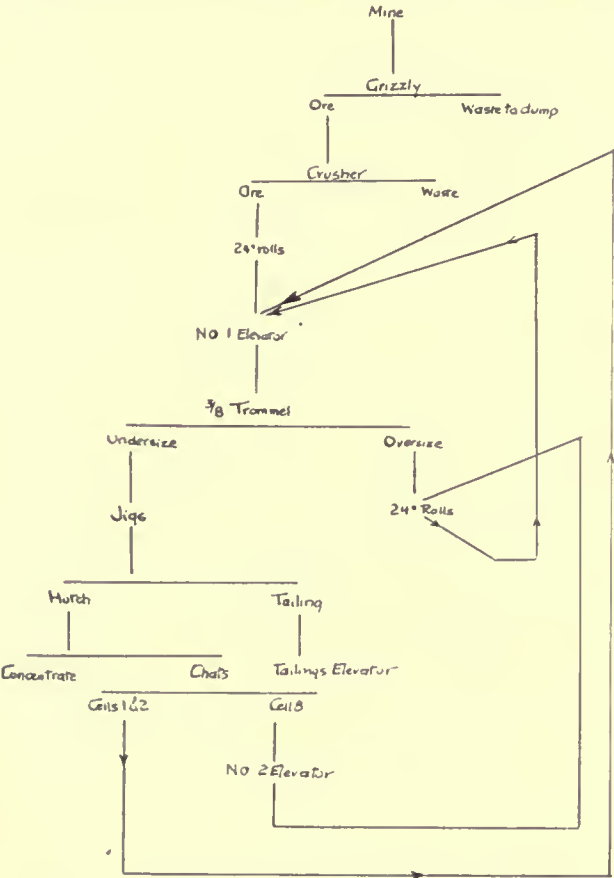

FIG. 1. FLOW-SHEET, 50-TON MILL, S-COMPARTMENT JIG.

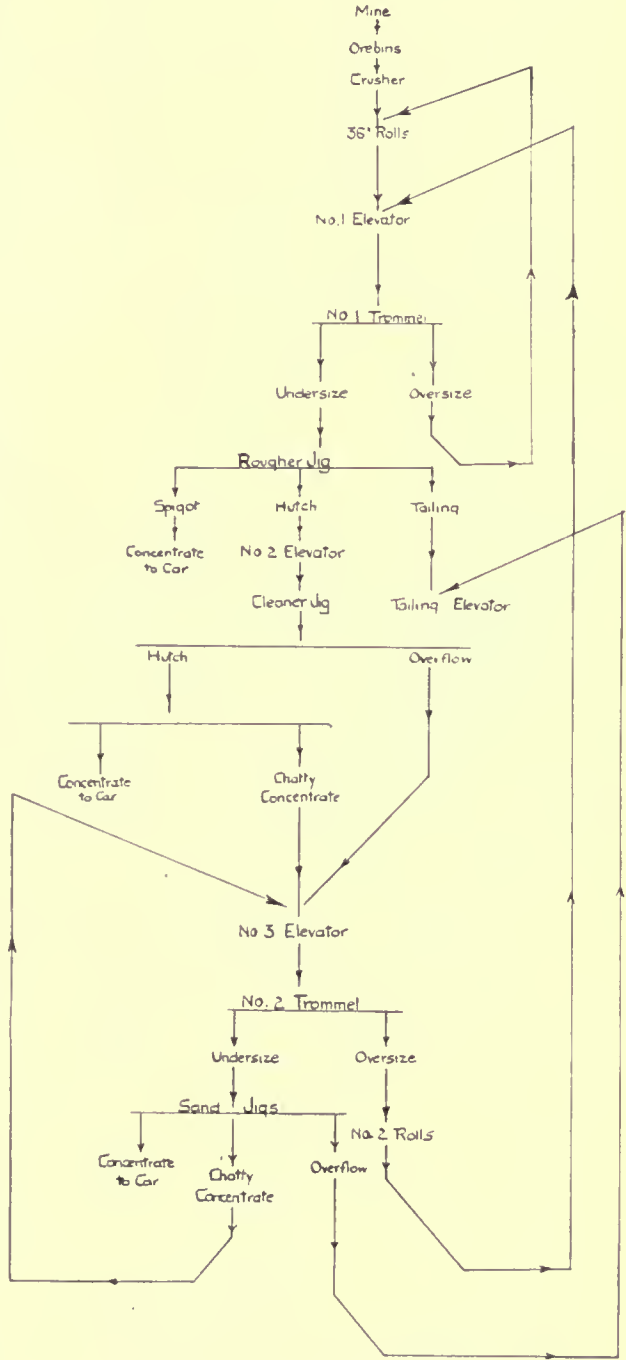

FIG. 2. FLOW-SHEET, 150-TON MILL.

tonnage through his mill there is only one thing to do—go ahead and try it, watching for free mineral in the tailing, and checking by assays. Only in this way can he get independent data. It may be said that the dirt may vary from day to day, one shift's run being much richer than the next. This is true, but it is probably better to risk a little undue loss in the tailing for a day or two and 'clean up the hopper,' than to disrupt the whole system and disorganize the work. Once such disorganization is started, it is easy to find excuses to continue it, and the irregularity will affect not only the mill, but the mine as well.

The labor needed for an ordinary zinc mill in Wisconsin will be about the same regardless of the tonnage milled. The following are usually employed, at the wages stated, per 10-hour shift:

1 millman, or jigman.....	\$3.00
1 helper, or mill 'backer'.....	2.25
1 crusher-man	2.25
1 grizzly-man	2.25

The millman is held responsible for the successful running of the mill and has authority over the others. He

it into a ear, but this is not usually expected of him, and is doubtful practice. The grizzly-man breaks the larger lumps of rock to breaker size, and usually throws aside the waste into a ear, which he runs over a dump. If only a small tonnage is hoisted, and the rock is pretty well broken underground, he can attend to both duties without trouble. Otherwise a earman helps him.

The equipment of an ordinary 50-ton mill consists of grizzly, crusher, rolls, trommel, elevators, and jigs (see Fig. 1). On account of the general flatness of the country, gravity mills are rarely seen. Bucket elevators are used to

lift the mill-feed from one point to another. A mill of the above description, with one set of 8-cell jigs, costs approximately \$10,000 to build, and takes about 90 days.

Tables are not commonly found. They have not thus far proved successful in making a clean separation of the limestone and jack in the finer sizes, but experimental data are lacking. No doubt tables could be devised to treat the finer sizes successfully, but this would mean closer sizing and more careful work generally throughout the mill. It is questionable if this would pay, considering the small size of the mills and the low grade of the resulting product. Instead of tables, sand-jigs are used in some mills to save the fine (see Fig. 2). These take the re-crushed product from the finishing jigs which might otherwise be carried over and sent to the tailing elevator. By adjusting the spigot taps, the concentrate may be drawn out as fast as desired, and either sent to the bin, or, if not sufficiently clean, back to the rolls, and so over the jigs once more.

The jigs are of the familiar Harz type, such as are common at Joplin. Sieves are either round-punched or slotted. Those with round holes are more common, but one operator reports that the slotted sieves last longer. The sizes vary according to the general scheme of crushing, whether coarse or fine. The sand-jigs usually have several 1/16-in. cells. A general arrangement in a mill crushing to medium size, stated in fractions of an inch, is:

Jig.	Cell No.					
	1.	2.	3.	4.	5.	6.
Roughing	1/4	3/8	3/4	5/16	5/16	3/16
Cleaning	1/8	3/16	1/4	3/16	3/16	1/8

The lead is drawn from the first cell of the roughing jig when there is but one set of jigs, or the first cell of the cleaning jig when there is more than one set. The scheme of treatment of a larger mill is shown in Fig. 2. A variation of treatment, common in the smaller mills, is to draw off fine iron sulphide, known locally as 'sulphur sludge,' from the third cell, from a 5/32-in. sieve. This product is sold subsequently to an acid works, and brings a few dollars per ton. Payment is made only for the sulphur content. It is believed that by this the grade of the zinc concentrate is raised. This so-called sludge carries 8 to 12% zinc, which, of course, is lost. The practice is of doubtful value, but where the mine is not equipped with a roaster, and is distant from a railroad, it may pay. It is also generally easier to sell high-grade than low-grade ore, and storing concentrate while waiting for buyers is an expensive operation.

The concentrate is drawn off from the jig cells through the hatches and also from above the sieves, through ordinary molasses spigots. In the latter case, the millman watches the product closely, to see that it has been properly cleaned before being run into the ear. This plan provides for the larger sizes that might not pass readily through the sieves, and saves the trouble of regrinding the coarse concentrate, with attendant loss. Where the dirt is rich and easily cleaned, the millman will sometimes shovel directly from the top of the jigs to the concentrate ear.

The water needed for the jigs, elevators, and rolls about the mill is considerable. Usually the mine-water pumped is utilized, but it seldom is sufficient, and must be re-used, after having been through the mill. Most mills have a pond or reservoir near by, for storing the water pumped during the night, and serving as well for a settling-pond. Centrifugal pumps are used for pumping from the pond to the jigs, a common size being the 4 inch. The amount of water needed for a 50-ton mill varies with a number of conditions. For ordinary ore, through a 1/8-in. trommel screen, perhaps 300 gal. per minute would be sufficient for an 8-cell jig. The amount increases with the number of jigs. Clean water is highly desirable, as water carrying slime invariably increases the amount of lime in the concentrate, coating it with a thin film. If 10 tons of water is used for every ton of rock milled, the amount will not be far wrong.

Water is also used on the grizzly for cleaning the mine rock as it comes up, thus enabling the grizzly-man to determine, by inspection, the ore from the waste. It is fed into the rock-breaker in a steady stream, performing the double purpose of carrying down the fine material through

the jaws and so preventing useless work on the breaker, with consequent sliming, and, second, of clearing the crusher of sticky and clayey dirt, which is frequently present.

Before being sent to the tailing elevator, the tailing is partly dewatered in a settling box, the excess water being sent back to the millpond as noted. The amount of water needed to carry off the tailing varies with the grade of the tailing trough, and with the size of the material. The water needed increases enormously as the grade decreases, and considerably more is needed to get rid of 1/2 than 3/8-in. material. Tailing is usually elevated 50 ft. or so, and then conducted out by troughs to the tailing pile. As the pile grows larger, more sections are added until there is no longer sufficient fall, and the trough chokes. In such a case, either the elevator is made higher, or another elevator, known as a 'booster,' is built on the tailing pile, and the dirt re-elevated. Cast-iron troughing, in half-moon shape, has been used to line the boxes in which the tailing flows, and has given excellent satisfaction. The friction is much reduced, and hence the distance the tailing may be conducted is increased. With such an arrangement, the minimum grade for 1/2-in. dirt is 1 3/8 in. per foot for a distance of 250 ft. This is about 11% grade. Wherever possible, it is better to make the grade considerably steeper than this, as there will be a substantial saving in the water necessary.

The crushers used in the district are usually of the Blake type, made by local foundries. The usual size is 7 by 14 in. The jaws are set for a 1 1/2-in. opening in the smaller mills, to 2-inch in the larger. The capacities are somewhat greater than usually found, due perhaps to the fact that the limestone breaks easily along well defined cleavage planes, and the principal formation in which the ore is found, the so-called 'oil-rock,' is quite soft. Repairs are at a comparatively low figure.

Rolls 24-in. diameter, with 14-in. face, are most commonly seen in the district. Usually there are at least two sets. Some of the larger mills use one set of 36-in. rolls, returning the oversize to the same rolls (see Fig. 2). These large rolls are set to 1/2-in. opening, and, having a larger angle of nip than the smaller size, can easily handle the product from the crushers. Their peripheral speed is lower, about 220 ft. per minute. The shells last a long time, under ordinary conditions. The relative efficiency of 36 and 24-in. rolls is an interesting question, but my opinion, for the conditions here, strongly favors the larger size. For coarse crushing there can be no doubt which is the better. The general condition always holds good, that the more the machinery is simplified, other things being equal, the greater the efficiency, and one roll is less bother than two. An interesting feature is the universal use of star-wheels on the first set of rolls. This dispenses with gearing the two rolls—always a dangerous practice—and permits the rolls to be set as far apart as needed, thus enabling the fine rock to drop through without further crushing, and largely preventing sliming. I have seen rolls run without stars in the district, but the choking nearly drove the millmen frantic. Scrapers are sometimes used on the rolls to take off the clayey dirt that sticks persistently.

The power required in these small zinc mills is not large. Exact figures are lacking, and few companies go by anything but rule of thumb. The mill shown in Fig. 1, and treating 60 tons in 9 hours, has a 50-hp. engine. The mill in Fig. 2 has a 75-hp. engine. Until recently power has been supplied by steam, but with the advent of an electric power company into the field, transmitting current at high tension and stepping down at the mines, induction motors are rapidly taking the place of the old engines. A noticeable point is that the power consumption, figured in kilowatt hours, varies more in accordance with the time the mill is run, than with the tonnage put through. In other words, if 150 tons is crowded through a mill in 9 hours, the kilowatts used will be less than if 125 tons is put through in 11 hours. This can be easily understood when the enormous friction of shafting and countershafting, slip in belting, etc., is remembered. The pumping and jiggling

power requirements are practically proportional to the time, not to the tonnage. Actual figures for a mill having two sets of jigs, crusher, 36-in. rolls, trommel, two elevators, and a centrifugal pump, show a consumption of 9440 kw. for mill running time of 237 hours. In this period it handled 3900 tons. This shows a consumption of 2.42 kw. per ton. The net kilowatt consumption per hour of mill-run was 39.8, or 53 hp. The mill is provided with a 75-hp., 3-phase, 60-cycle, 220-volt, induction motor.

Consideration of the fact that the time of running affects the power consumption more directly than the tonnage put through, is a powerful argument for crowding a mill to the limit of economical extraction. Especially is this the case if the proportional cost of power labor is included along with the cost of power consumed. This will be shown later in the résumé of cost data for such a mill.

The cost of repairs in a small zinc mill depends largely on the care of the millmen and the watchfulness of the management. The chief items of expense are sieves, screens, belting, and jaw-plates and toggles on the crusher. Elevator belts are an important item of expense. It pays to get the best and most durable belting, and stick to it. The life of screens and sieves varies with the character of the milling. Sieves should be cleaned and the holes freed from clogging particles every day or two—the beds being completely removed, and then shoveled back—the process called locally ‘spanking jigs.’ Star-wheels and gears on the rolls cost more in repairs and renewals than do the shells, which frequently last two years. Cost of repairs, taken for a year’s time on a mill treating 125 tons per 10-hour shift, were \$0.039 per ton. In another mill of inferior design and ancient structure, treating about 200 tons in two shifts, the cost per ton was \$0.064. In a third mill, where the superintendent and millmen were both extraordinarily careful to keep down expense, the cost was only \$0.020 per ton. Repairs no doubt vary more in proportion to tonnage than either power or labor, though the inevitable depreciation of plant and machinery must go on largely independent of the tonnage put through.

The costs of milling in the Wisconsin field may now be briefly summarized. They may be divided into labor, power, and repairs. Depreciation should be included separately. Only actual mill labor is included. Power is figured at \$0.025 per kilowatt, with no allowance for engineer’s wages. For a mill treating 75 tons of 10% ore per 9-hour shift the result is as below:

Labor:	Total.	Per ton milled.	Per ton concentrate.
Mill-man	\$3.00		
Helper	2.25		
Crusher-man ..	2.25		
Grizzly-man ..	2.25		
	\$11.75	\$0.156	\$1.56
Power, 40 kw. (9 hr. = 360 kw.-hr.)	9.00	0.120	1.20
Repairs	2.25	0.03	0.30
Total	\$23.00	\$0.306	\$3.06

It will be noted at once that labor forms over 50% of the cost. As stated before, the same crew will be needed for a 75-ton as for a 125-ton mill unless the ore should get overwhelmingly richer. Suppose it is decided to put 100 tons through the same mill. The ore will probably make but 9% concentrate, as lower-grade stuff can and will be mined. The milling costs will then be as below:

	Total.	Per ton milled.	Per ton concentrate.
Labor	\$11.75	\$0.117	\$1.30
Power, 50 kw. (9 hr. = 450 kw.-hr.)	11.25	0.112	1.12
Repairs	3.00	0.030	0.23
Total	\$26.00	\$0.259	\$2.75

Such a change as this—a saving of 4.6c. for every ton of rock milled—may mean that a mine can be run at a profit instead of a loss.

JOPLIN ZINC ore shipments for the week ended June 1 were 4899 tons of blende, at \$53.95 per ton, and 200 tons of calamine at \$28.81 per ton. The estimated surplus stocks in producers’ bins were 900 tons, as against 7500 in 1911.

Free Use of Timber From Public Lands

By T. D. WOODBURY

The Acts of March 3, 1891, and June 3, 1878, permit the free use of timber from unreserved land not within national forests under certain restrictions and conditions. The first of these acts as amended provides that residents of Colorado, Idaho, Montana, North Dakota, South Dakota, Wyoming, New Mexico, Arizona, and the District Alaska, the gold and silver regions of Nevada, California, Oregon, and Washington, and the territory of Utah may cut timber from the public domain, free of charge, for agricultural, mining, manufacturing, or domestic purposes under rules and regulations made and prescribed by the Secretary of the Interior. To justify the cutting of timber under this act, the person claiming its benefit must be a resident of the state or territory in which the timber is cut and the timber must be used for a purpose named in the act and within the state or territory where it is cut and must not be disposed of by sale or otherwise. There are two exceptions to the requirement that the person claiming the benefit of the act must be a resident of and the timber must be used in the state or territory where it is cut, as follows:

The Amendatory Act of March 3, 1901 (31 Stat. 1439) provides that residents of the states of Wyoming and Montana may cut timber for use in either state from the south slope of the Pryor mountains in Montana lying south of the Crow Reservation, west of the Big Horn river, and east of Sage creek.

The Act of July 1, 1908, (30 Stat. 619) provides: “That it shall be lawful for the Secretary of the Interior to grant permits, under the provisions of the eighth section of the Act of March third, eighteen hundred and ninety-one, to citizens of Idaho and Wyoming to cut timber in the state of Wyoming west of the continental divide, on the Snake river and its tributaries, to the boundary line of Idaho for agricultural, mining, or other domestic purposes, and to remove the timber so cut to the state of Idaho.”

Persons who desire to avail themselves of the privileges of the Act of July 1, 1898, must make application to the Secretary of the Interior for a special permit.

The Act of March 3, 1891, provides specially that it shall not operate to enlarge the right of any railroad company to cut timber on the public domain. Under the regulations of the Secretary of the Interior (29 L. D. 572), the amount of timber which may be so obtained without special permit from the Secretary of the Interior is limited to the stumpage value of \$50 in one year.

These regulations provide that persons who are entitled to its provisions but are not in a position to procure the timber themselves may employ another as agent to do the cutting, removing, and sawing, provided the agent is paid only for time, labor, and other legitimate expenses exclusive of any charge for the timber. The agent, furthermore, cannot be paid with a share of the timber, but no person, whether acting for himself or as agent for another or otherwise, can cut more than the stumpage value of \$50 in one year without permit. Persons wishing to avail themselves of the free use privilege of this act should apply to the Chief of Field Division having jurisdiction over the land, who will supply them with application forms. The applications should set forth the names and legal residences of persons applying for timber, the names and residences of persons who are to use the material, the amount of timber required for each person, and the use to be made of it; also the date upon which cutting will begin and the description of the land from which the material is to be derived. Any cutting done before the permits have been finally approved by the Commissioner of the General Land Office is done at the applicant’s risk, subject to such approval.

The Act of June 3, 1878 (20 Stat. 88), which applies only to unreserved land not within national forests, pro-

vides that all citizens of the United States and other persons residents of the states of Colorado, Nevada, New Mexico, Arizona, Utah, Wyoming, Dakota, Idaho, Montana, and all other mineral districts of the United States may acquire for building, agricultural, mining, or other domestic purposes such timber as they may have need of from mineral public lands not subject to entry under existing laws of the United States, except for mineral entry. The timber can only be acquired subject to rules and regulations prescribed by the Secretary of the Interior, which provide for the protection of timber and of undergrowth growing upon such lands. The provisions of this act do not extend to railroad corporations. The regulations of the Secretary of the Interior mentioned above require that persons felling or removing timber under the provision of this act must utilize completely each tree cut that can be profitably used and must dispose of the refuse from cutting so as to prevent the spread of forest fires.

The other Act of June 3, 1878 (20 Stat. 89) prohibits the cutting of timber on any lands of the United States in any public land states; provided that any miner or agriculturist shall not be prevented from clearing his land in the ordinary working of his mining claim or preparing his farm for tillage, or from making timber necessary to support his improvements. These two acts are to be construed together. The first applies to mineral lands only in the states mentioned; the latter prohibits the cutting on non-mineral in all public land states, with the exceptions noted above. The Act of March 3, 1891, provides a defense for criminal prosecutions and civil actions for timber trespass in the states mentioned in this act and its amendments.

Homestead.—A homesteader who has made bona fide settlement upon public land and is living upon, cultivating, and improving his claim in accordance with the law, with the intention of acquiring title, has the right to cut such timber as is necessary for improvements on his claim, and also for fuel. If in clearing the land in good faith for cultivation there is a surplus of timber over the amount needed for improvements, the claimant may sell or otherwise dispose of such surplus. He cannot, however, denude the land of its timber for the purpose of sale or speculation before he has acquired title. The cultivation of the land must keep pace with the clearing step by step.

A homesteader who has never had possession of the land included in his claim, and whose entry has been cancelled, cannot by a subsequent purchase of the land from the Government acquire title to the timber cut prior to his purchase and thereby relieve himself of liability in a civil suit for the value of the timber. Except where it is necessary, in order to clear his land, a homesteader has no right to cut trees for the purpose of sale or profit. Entrymen under the Act of June 11, 1906 (33 Stat. 233) have the same rights as other homesteaders.

Settlers.—With respect to cutting timber from his claim the rights of a bona fide settler upon unsurveyed public land are precisely the same as the rights of a homestead entryman upon surveyed land.

Mining Claims.—The owner of an unperfected mining claim upon public land may cut such timber as is necessary for use in or to permit the development of the claim. (Act of June 3, 1878, 20 Stat. 89.) The burden of proof is on the claimant to show that the use of the timber on a claim other than that on which it is cut will tend to develop the claim on which the cutting was done. In no case can such use of timber be justified on a claim not within the same group as the claim from which the timber was cut. The owner of a patented claim may, of course, dispose of the timber as he may desire.

The cutting of timber for sale in advance of mining operations under the pretext that the stumps would rot and therefore be more easily removed is not necessary to mining operations and is therefore unlawful. An occupant of a mineral claim who has applied for a patent has no right, before the purchase price is paid and he receives a certificate, to cut the timber on such claim with intent to export or remove the same, and a license from him to so cut the timber is no protection to the licensee, as against

the Government. The exclusive right to occupy and work a mineral claim, given to the locator by mining laws during his occupancy, does not segregate such claims from the public domain so as to exclude such land from the operation of Rev. Stat. 2461, 20 Stat. 89, and 27 Stat. 348, making it a misdemeanor for any person to cut timber on the public lands. The use of timber from any unpatented claim for the construction of a mill or other reduction works, or for the roasting or reduction of ores, will not be permitted, and all timber cut for such purpose will be held to be cut in trespass.

Free Use from National Forest Land.—The Act of June 4, 1897, as amended by the Act of February 1, 1905, provides that the Secretary of Agriculture may permit, under regulations to be prescribed by him, the use of timber and stone found upon forest reservations, free of charge, by settlers, miners, residents, and prospectors for minerals for firewood, fencing, building, mining, prospecting, and other domestic purposes as may be needed by such persons for such purposes, such timber to be used within the state or territory, respectively, where such reservations may be situated.

Forest rangers are authorized to grant permits for free use on national forests up to \$20 in value. Supervisors up to \$100 in value, and the Forester up to \$500 in value. All requests for permits for an amount of material exceeding \$500 in value are acted upon by the Secretary of Agriculture. Free use of permits under this regulation are granted to the various classes of citizens enumerated in the Act of June 4, 1897. In the application of this Act, it is the object of the Forest Service to assist prospectors in their work and to encourage and aid settlers who have not on their own lands or claims or on land controlled by them a sufficient and accessible supply of material for their work. Applications for free use should be made to the local forest officials. Each case is thoroughly considered on its merits and in applications not clearly covered by laws and regulations, it is the policy to grant free material to all local residents who because of their financial condition may not reasonably be required to purchase timber. A distinction is drawn between public or personal and commercial use. Residents of towns and villages engaged in business are expected to purchase building material for town dwellings and other home structure and for fuel. Settlers under the homestead laws who have not yet improved their tracts of land sufficiently to derive a livelihood from them are given a liberal allowance of material for their own use.

Wherever dead or defective timber will serve the applicant's purpose, free use is restricted to such material. Such timber is not only a fire menace and for this reason should be removed, but its cutting improves the condition of the forest and increases the growth of the remaining stand. When it can be conveniently done, free use areas are laid off adjacent to villages, from which applicants can readily derive their material. In the enforcement of the free use regulations, all unnecessary restrictions are waived and an effort is made to serve the public in this respect as promptly as possible. In order to guard against damage by fire, it is necessary to require the applicant to pile the limbs and tops or other debris resulting from cutting in such a manner that it can be readily burned and thus got rid of at the proper season of the year.

IN Cripple Creek the Miners' Protective Association has been issuing cards to all employees and owners for the last two months. Since April 3, 2470 cards have been given out, and 37 applicants have been refused. A number of miners have felt that it would be folly to ask for cards at the Cripple Creek office, and have left the district. In this number are men who in the past have worked other men's cards. It was largely to eliminate this practice that the new association was formed among the miners. Not only the laborers and miners are required to have cards, but it is equally necessary for the mine owners and officials to take them out, under the rules of the association. The men working in the Isabella, Stratton Estate, and El Paso, are yet to be examined and given cards.

Prospecting Drill Records

By CHARLES H. WATERS

Drills used for prospecting gravel deposits having dredging possibilities can give data covering the four following conditions: (1) the value per cubic yard and the distribution of gold; (2) the character of the gravel; (3) the bedrock contour and its character; (4) the water-levels, including maximum and minimum heights of the surface above and the extreme depths below the water-level. All facts which a drill can give when carefully and properly handled must be recorded with care, in order to secure accurate samples as well as other important data from which the final estimates must be made. Below is shown a form for making such a record.

At the top of the form is found the 'Kind of prospecting,' the form being available for either drill or shaft prospecting. The name and size of the drill or the size of

CONVENIENT FORM OF DRILL RECORD.

the shaft should be noted. In the accompanying example a drill is assumed to be used. Under the heading of 'Time Log'

is found hour when drilling began. The next space is for hour when all work is finished. Under 'Hours Drilling' is put the net time used in drilling. The next space is used to show the time used in pulling the casing from the hole; following this is a space to record time used in moving from hole to hole. Under 'Time Lost' come any unusual happenings which delay the work, and the next space is used to explain the cause of the delay. In the last space is kept a record of the total number of feet drilled during the day. Under 'Values' is found a brief summary of the most important facts. The form is self explanatory.

About the only change that I have made from the more common forms is in the 'Field Log,' which is a graphic record of the following conditions: rotation or driving of the casing; location and amount of soil, sand, and clay; size and hardness of the gravel; size of the gold and number of the colors and where they occur. In the column under head of 'Character of Gold' is recorded such characteristics of the gold, as whether smooth or rusty. In the last column is shown the water-level, by lines drawn, as shown, from the bedrock to the surface of the water; in this case 11 ft. 6 in. from the surface. Under 'Remarks' many things can be added, such as location of the hole, kinds of gravel, amount of black sand, anything, in fact, that may be considered of importance. If in driving the casing I find a smaller core than should have been obtained, I note this fact under 'Remarks,' stating at what point it occurred and the amount the core lacked. A record is also made when too much is obtained. I consider the amount of core very important, and I always mark it on a rod on which the drill wrenches are kept, thus having marks which indicate how much core is in the casing at any time whether drilling or pumping.

Ore Reserves of the Rand

In connection with the interesting description of the largest producers on the Rand, elsewhere in this issue, a summary of the ore reserves of the principal operating companies will be of interest. During the first quarter of 1912, according to the monthly statements of the Chamber of Mines, the companies at work on the Rand milled 6,211,555 tons of ore which yielded 29s. 8d. per ton at a working cost of 19s. per ton. The known ore reserve of the Rand therefore is approximately four years supply.

The tables below, prepared by the *South African Mining Journal*, classify the ore reserves of Rand mines according to the various controlling houses or groups, and deal only with profitable, fully exposed, and fully valued ore, except in one or two special instances. The group aggregates are:

	Tons.
Central Mining & Investment Corporation.....	36,999,442
Affiliated companies with head offices in Natal..	1,358,800
Consolidated Gold Fields of South Africa.....	9,199,000
East Rand Proprietary	6,716,605
Anglo-French group	1,753,370
General Mining & Finance Corporation.....	5,842,556
S. Neumann & Co.....	4,183,962
Johannesburg Con. Investment Co.....	5,814,231
Randfontein-Langlaagte group	6,940,166
A. Goerz & Co.....	1,949,207
Consolidated Mines Selection.....	1,925,346

Total 82,682,685

If to this total be added ore partly developed or partly valued, the great bulk of which may be assumed to be profitable, and there be also added the tonnage of ore awaiting mining in a few comparatively unimportant mines not included in the above, a grand total of slightly over one hundred million tons is reached.

In these calculations no account has been taken of the many millions of tons of low-grade ore—the accumulations of years of exploitation—which are standing developed in the mines. Much of this low-grade ore verges on the profit line. It needs but a happy swing of the pendulum of the industrial clock to transfer several millions of tons from the unprofitable to the profitable side of the Rand ledger.

Details of gold content and tonnage of the principal groups are as follows:

<i>Central Mining & Investment Corporation:</i>		
	Tons.	Dwt. per Ton.
Bantjes Consolidated	896,087	7.3
City Deep	2,078,805	8.1

Copper Producers' Association Report

The Copper Producers' Association statement, June 8, shows a decrease during the preceding month in accumulation in this country of 15,450,386 lb. The details are as follows:

	Pounds.
Stock of marketable copper of all kinds on hand at all points in the United States, May 1, 1912	65,060,029
Production of marketable copper in the United States from all domestic and foreign sources during May	126,737,836
Deliveries for consumption, May.....	72,702,237
Deliveries for export, May.....	69,485,945
Stock of marketable copper of all kinds on hand and at all points in the United States, June 1.	49,615,643
The changes in surplus since June 1, 1911, have been as follows, in pounds.	

	Increase.	Decrease.
June, 1911		8,561,768
July		19,695,306
August		4,297,357
September	7,453,355	
October		5,897,214
November		23,212,454
December		22,330,493
January, 1912		22,173,252
February		3,301,944
March		572,431
April	2,927,829	
May		15,450,386

MOST of the gold mined in Tasmania comes from Beaconsfield, on the Tamar river, near Launceston. This is an exceedingly rich mine, but on account of the great cost of pumping out water, some of the largest pumps in the world being used, the net profits in recent years have been small, and last year there was a slight loss, suggesting the possibility that unless the mine can be more economically worked it may have to be closed. Osmiridium has lately been discovered and mined in Tasmania, and the output, for which there is a good demand at nearly \$35 per ounce, promises to show much increase in the future.

FRENCH capitalists have raised \$1,030,000 for exploiting Sakhalin oilfields, and have signed an agreement with the Sakhalin Oil Co. An expedition has been sent to examine the fields.

NEW YORK

REPORT OF COPPER PRODUCERS.—OHIO COPPER CO'S REPORT.—COBALT SHARES INACTIVE.

The report of the Copper Producers' Association shows copper stocks to have decreased 15,450,386 lb. European copper stocks are also reported to show a large decrease, and it is quite evident that higher prices for the metal will rule during the coming month. Copper outputs are increasing in a ratio that a short time ago would have been considered most dangerous. The Anaconda production for May was 25,000,800 lb., as against 21,000,700 a year ago, 24,816,593 in May 1910, and 26,665,951 lb. in May 1909. The entire output of Butte was 29,082,362 lb. in May, which compares with 28,929,040 in April and 20,791,460 in May one year ago. The Phelps-Dodge output in May was 12,009,086 lb., as against 11,911,063 in April. The Calumet & Arizona output was 4,424,000 lb. in May, as compared with 4,104,000 lb. in April. The

report is that in regard to the rolls installed by E. A. Wall. The average cost of handling the ore was 26.73c. per dry ton. This is considered a remarkably low mining cost. The vertical rolls installed by Mr. Wall have not yet fulfilled all of his predictions, but the engineers are confident that a complete success can eventually be obtained. Ohio Copper has dragged for many years, and its market has suffered accordingly. The Heinze influence seems to have been a handicap to Ohio as well as to the other properties under that control. A dividend of 25c. per share is expected to be declared by the Greene-Cananea. The management is installing three new converter shells of the Anaconda type which will much enlarge the capacity of the smelter. The usual list of Guggenheim dividends have been announced. These include the disbursements by Nevada Consolidated, Utah Copper, Yukon Gold, and the Guggenheim Exploration Company.

While it is true that the public lacks faith in the present copper market, it is evident that some of the individuals who know copper from long years of experience are full of faith in the future of the metal. Mention has been made many times of the amount of money

GENERAL VIEW OF SMELTER, GREENE-CANANEA COPPER CO.

British Columbia Copper Co. made a record output in May, producing 1,054,000 lb. copper and earning net profits for the month of \$58,000. The British Columbia Copper Co. is to resume dividends at the rate of 3% quarterly. Giroux has at last enrolled itself as a regular shipper and is sending 1200 tons of ore daily to the Step-toe concentrator of the Nevada Consolidated. Tuolumne Copper is another of the smaller independent producers that is about to resume dividends. This company is now shipping 300 tons of ore per day to the Washoe smelter, the ore running about \$12.80 per ton. A 15c. dividend will be declared in July, payable August 15, if present plans mature. The Old Dominion Copper Mining & Smelting Co. has declared a quarterly dividend of \$1.25. This is an increase of 25c. over the distribution made three months ago. The old Santa Fe Gold & Copper Co. is starting up and expects to handle 120 tons of ore per day at its smelter. Recent reports indicate a copper cost of 11c. It is probable that further furnace capacity will be added as soon as possible. The Ohio Copper Co. has just made a report upon its operations of the past six months and shows a profit of \$109,477. The company still has in its treasury \$754,000 of its bond issue which it has been unable to market. The interesting part of

spent by J. B. Haggin and his associates in developing the Cerro de Paseo Mining Co. in Peru. Now it is stated, on apparently good authority, that Mr. Haggin and his friends are planning the development of another property in Peru which is to equal, if not surpass, the older mine. The ground is said to show a vast body of ore that assays 15% copper and 8 oz. silver, so situated that when the Panama canal is done the product can be laid down in Liverpool as cheaply as metal transported from Arizona or Montana. The property is said to be an immense one that will require a vast amount of money and years of time to bring to a point of full production.

At the recent meeting of the Amalgamated Copper Co., William G. Rockefeller was elected a director of the company in place of John G. Morony, who has long been connected with the legal staff of the company. An active market is being made on the Curb for the El Paso of Cripple Creek. Recently the stock scored an advance of ten points in one day, selling up to 91c. per share. It is stated that El Paso has larger orebodies in sight now than at any time for several years past, and the advance is said to have been made solely upon improved mine conditions.

Cobalt activities are at a minimum. Regular disburse-

ments are being made by the Buffalo, Nipissing, and other properties that are producing. One interesting feature is a revival of the story of the contemplated purchase of the Chambers-Ferland ground by the La Rose. The Chambers-Ferland is a small property which lies between the Nipissing and the La Rose in such a manner that it has long been considered almost inevitable that sooner or later the property would be absorbed by one or the other of the adjoining mines. The stockholders in the Chambers-Ferland have had a long and weary wait for some action and will welcome the deal if consummated on any reasonable basis. It is stated that the Guggenheim interests have exercised their option on the Needles group of properties which lie south of the Southwest Miami in the Globe-Miami district. The price paid is said to be \$625,000, and work will begin immediately. There seems to be as much danger of a 'runaway' market in zinc as in copper. New record prices are being established each week. The present market is around \$59 per ton. Prices have been jumped at the rate of about \$2 each week, and in spite of heavy shipments, further advances are expected. Zincblende sold last week at \$61.

BOSTON

LITIGATION AND THE OLD DOMINION.—POSSIBILITIES OF AH-MEEK.—BUTTE & SUPERIOR AS A ZINC PRODUCER.

It is said that A. S. Bigelow and G. M. Hyams, the twin copper litigants, despite adverse decisions, will keep on fighting in the courts. Bigelow and Hyams are of litigious propensities and are not at all popular in Boston because of their lawsuit activity. Hyams has appealed from the decision of the United States District Court denying him the permanent injunction he sought to keep Calumet & Hecla from voting its Tamarack and Isle Royale stock in favor of the new milling arrangement, which is believed to promise a great economy in treating the ore. Bigelow is represented as being as full of fight as ever, notwithstanding the United States Supreme Court appears to have effectually disposed of the celebrated case which he has been defending against Old Dominion for the past ten years. Bigelow is no longer active personally in his antagonism to the movements of Calumet & Hecla, but Hyams is represented as having received his mantle in that realm of disturbance. It is said that Bigelow, in case restitution of promotion profits in Old Dominion is enforced against him, will sue the estate of the late Leonard Lewisohn for its share of the disgorgement, Lewisohn having been Bigelow's partner in the original enterprise when the Old Dominion was incorporated.

The Old Dominion company, either of Maine or New Jersey, keeps well to the front in the copper news, whether from the standpoint of dividends or litigation. The Old Dominion Company of Maine, the holding company, has again increased its dividend rate, which is now \$1 per share quarterly. A year ago the company paid 50c. per share; six months later it paid 50c. regular and 50c. extra per share, and three months ago 75c. per share. The company is now on a basis of \$4 per share annually, which compares with \$1.50 annually for 1909, 1910, and 1911. The rate in 1908 was 50c. The remarkable dividend action has been the result of the United Globe Mine, of which the Old Dominion Company of Maine holds the 23,000 shares outstanding, declaring its third dividend this year. In January United Globe paid \$5 per share, in April \$3, and the current declaration is \$4.50 per share. United Globe has not paid any dividends since 1907, when they amounted to \$4 per share. In 1906, \$6 per share was paid, and in 1905, \$6.50. This makes the total to date, \$29 per share, or \$667,000. The operating Old Dominion company is a New Jersey corporation. This corporation is the one which benefits exclusively by the award of \$2,464,000 made in the judgment affirmed by the United States Supreme Court against A. S. Bigelow. There is some talk about the creation of trust receipts by the operating company for the purpose of participating in the possible recovery against Bigelow being unconstitutional and a matter to

be fought out in the courts. Some day Old Dominion will be no longer a hydra-headed or bifurcated company, and everything will be consolidated under one head. Then it will be possible for the layman to know which company he is reading about.

Calumet & Arizona's declaration of the usual dividend came somewhat as a surprise here. It had been expected that the company would fall in line under the pressure for an increase of dividends from the copper companies. Copper Range declared the usual dividend. Mohawk is expected to increase its rate for 1912. Wolverine will make no increase. No large dividends may be expected from Copper Range and Wolverine until there is a material change in their mine conditions. Wolverine is not much more than earning \$10 per share at present. It formerly paid \$10 per share in dividends, but was obliged to reduce its rate.

Ahmeek is attracting attention, not on account of its activity but its constant advance in price. It is now selling around \$350 per share, its high point, and an order for a thousand shares would probably send it up even with Calumet & Hecla, around \$500 per share. Ahmeek is the richest amygdaloid property in the Lake country. It is the lowest-cost producer in that section and one of the lowest in the world. It is now the most important in point of revenue among the subsidiary assets of Calumet & Hecla. Ahmeek is on a dividend basis of \$16 per share, but on a 17½c. metal market it has a profit of 10c. per pound, amounting to \$1,600,000. This is equal to \$32 per share, or double its present dividend rate. Ahmeek directors will meet in a few days for dividend action, and there is talk that the rate will be increased, inasmuch as the company is in an excellent position to do so by reason of higher-priced metal and increasing output. Ahmeek has been producing this year from its No. 1 and 2 shafts, plus small contributions from its more recent No. 3 and 4 shafts. Its present mill capacity limit has been reached, treating something over 50,000 tons of rock per month, but on account of the two new shafts coming in with added production the mill equipment will be enlarged accordingly. The company is pledged to spend \$600,000 the next two years in new shafts and mill equipment. It is believed that this can be taken care of out of the company's earnings above dividend distributions on the present metal market. Ahmeek is traded in on the Exchange. While on the Curb it was known as 'The Little Calumet & Hecla.' There are many points in common between the two properties—the character of the ore, the ownership, the high price and wide fluctuations of the stock, and the promising outlook. A year or 18 months from date Ahmeek should be producing 30,000,000 lb. of copper per year. It is indeed a remarkable copper property and will probably in the future vie with Calumet & Hecla as a top-notch property in mining stock quotations. Calumet & Hecla once touched an even \$1000 per share, in the early part of 1907, and if Ahmeek keeps up the way it is going, it may do likewise. In 1906 it sold at \$10 per share. Of its entire issue of 50,000 shares, 24,800 are owned by Calumet & Hecla, which company is believed to be accumulating the stock from time to time as it figures in the transactions of the Exchange.

The mine, metal, and market record of Butte & Superior is exciting Boston traders. After a flat failure in finding profitable copper ore, Butte & Superior has developed into one of the largest zinc deposits in the world. The property is immediately north of North Butte, which in the early years of Butte's career was considered to be outside of the copper zone of that district. But North Butte cut the Edith May vein at a depth of 800 ft., working it from that level down to 2300 ft., making a wonderful record of ore output. Butte & Superior, on the theory that the copper zone continues beyond North Butte, put down a 3-compartment shaft 1600 ft. This shaft started in with copper ore of mediocre tenor, changing to zinc, a metal which was unexpected and unsought. However, the zinc ore is clean in character, practically free from iron, making it—unlike the zinc at Leadville—amenable to concentra-

tion. Butte & Superior now has a supply of almost 1500 tons of zinc ore blocked out. To every pound the percentage runs better than 25%, or over 500 lb. of solid zinc in a ton. On the 900 and 1400-ft. levels the company has opened wide orebodies which more than sustain the average mentioned in zinc recovery. The orebody on the 900-ft. level also carries 135 oz. of silver per ton. Persistence of ore is especially indicated at this point. The company's new mill, which has been operating about three weeks, has attained a saving of over 90%, while the old mill could not extract more than 45 to 50%. The new mill was designed for a capacity of 500 tons per day per unit, but has been crowded to as high as 625 tons per day. Recently Butte & Superior has been selling around \$45 per share. Its low point for the year is around \$19. So sensational have been the developments of this zinc deposit, so efficient the new mill, and so important the financial and technical interests now identified with the company, that some people suggest a price of \$75 per share. Every now and then the Butte geological viewpoint has to be changed. Undoubtedly Butte is going to extend its producing boundaries, not only to the north, but to the south, the original discovery section, where there are such properties as Butte Central and Davis-Daly. The rich find made on the 1900-ft. level of Davis-Daly points to the probability of that property being within the zone of the Rarus fault, which the Butte Central management has traced in its property from the 100 to the 500-ft. level.

SALT LAKE CITY, UTAH

UNITED STATES COMPANY ENGAGES IN COAL BUSINESS.—
URANIUM IN UTAH.—COMPANY REPORTS.

The last of the options on coal properties held by the United States Smelting, Refining & Mining Co. has been exercised by that company, which has now added the control of the Consolidated Fuel Co. to its other holdings. Nearly \$1,600,000 in cash was paid over for this property and some minor holdings. The development of the mines and the building of a connecting railroad will involve a total expenditure of approximately \$10,000,000, which the United States company has already financed. The purchasers had already acquired the Castle Valley and Black Hawk holdings, together with a large area of undeveloped coal land. They are now preparing to develop all the properties extensively on a large scale, expecting to increase the production of coal by 3,000,000 tons annually within the next two years, and eventually to several times that amount. This means practically doubling the entire production of the state immediately. While the United States company is itself a large consumer of coal and coke, this fact has had small bearing on its purchase. The main idea has been to furnish a large supply of cheap coal for manufacturing and domestic purposes in Salt Lake City and vicinity, and to invade the markets of the Pacific coast. The Utah bituminous coal is recognized as of better grade than most of the competing coals in this market, but the Utah producers have been handicapped by freight rates. This situation has been improved, however, and a case now pending before the Interstate Commerce Commission, if won by the shippers, will still further aid the producers. Furthermore, the new Western Pacific railroad is looking for traffic. The United States company is planning to build the Utah Coal railway, to connect the mines with both the Rio Grande and the Salt Lake routes. The survey has already been made, but it is possible the Rio Grande may hold the business by building the road itself, providing suitable arrangements can be made with the mining company. Another market which the new owners are seeking is that of the United States Navy. Previous efforts in this direction have not been successful, but the new owners believe they will be able to secure a contract on the merit of the coal and service.

Rare metals are attracting increasing attention in Utah, especially uranium, vanadium, and tungsten. The value of the carnotite deposits near Green River, in eastern Utah, is no longer a matter of doubt. At present only one

property is a regular shipper, but it has become one of the big producers of the world, and there are a number of promising prospects. This property consists of over twenty claims, 14 miles southeast of Green river, and is being operated in the name of 'Angus Cameron, Agent.' The ores are marketed through David Taylor of Salt Lake City, and it is understood that they are shipped to Hamburg, Germany, although a great deal of mystery is maintained about the property, its backers, and the outlet of its ores. It is working 20 men, and is shipping about a carload of ore per week. The ore lies practically on the surface, and is easily handled. As the market value is said to be \$100 to \$200 per ton, the operations are apparently profitable, despite the freight to Europe. Another property of apparent promise is that of Jesse E. Inman, of Green River, which is preparing to begin regular shipments within about a month. There are a large number of prospects, including some properties of merit and some which are in the hands of men who mine with their lungs. Deep Creek, in the western part of the state, is the centre of interest so far as tungsten is concerned. The Willson brothers have been working some tungsten claims there at intervals for years, without as yet accomplishing great results commercially, and now other discoveries are reported in that vicinity.

Ohio Copper, according to the official report, earned \$109,477 for the six months ended March 31, and \$159,827 for the fiscal year. This is less than the 'unofficial reports' which have been coming out from time to time, but still shows a profit, which can be greatly increased when the company can adjust its finances so as to provide the needed additions to its equipment. The Silver King Coalition, of Park City, has held its annual meeting and re-elected the old board. Thomas Kearns, the general manager, announces an early resumption of dividends. This property has produced approximately \$25,000,000 of ore and paid over \$11,000,000 in dividends. It suspended dividends during recent litigation, which is still pending on appeal, but, it is now announced, the company has enough in the treasury to pay the big judgment of the Silver King Consolidated and still have sufficient surplus to allow the resumption of dividends.

ELY, NEVADA

OPERATIONS OF THE GIROUX.—POWDER TESTS, NEVADA CONSOLIDATED.—REORGANIZATION OF THE ELY CENTRAL.

The Boston-Ely company is diamond-drilling, by contract, from the bottom of the 1200-ft. level. On this level there is a 30 to 40-ft. vein of soft oxidized iron-stained ore with a little carbonate of copper and occasionally a specimen of native copper. The limestones here are much fractured and soft. On this account the diamond-drill hole was cased as far as possible. Recently a little powder was used in the bottom of the hole; it was then filled with cement and drilled out again. The drill-hole is expected to cut the oxidized vein. Water for steam purposes is hauled from Giroux.

At the Veteran mine of the Nevada Con. there are about 330 men on the payroll, all but 30 of them being foreigners. This mine is shipping an average of 1100 tons per day, of ore assaying above 3% copper. Recently a winze sunk from the lowest level penetrated a body of 6% ore, said to be of sufficient amount to materially extend the life of the mine. The underground workings are claimed by the miners to be dangerous. Americans will not work there except under necessity. They are generally hard-rock miners, not accustomed to the caving system, and on this account it probably appears more dangerous than it really is.

At the Giroux mines the only work being done at the Alpha and Giroux shafts is the pumping of about 600 gal. per minute from the latter, to hold the water-level at 1400 ft., where it comes from a long drift running east only toward the Alpha shaft. The object is to drain the above area that was flooded at the time of the fire last August. All machinery, tracks, and cars have been taken

out from all the levels. It is not expected that any further work will be done there until such time as shipments from the Morris shaft will warrant. The Alpha shaft-house has been entirely dismantled. The shaft where the cave-in occurred is so dangerous that the miners refuse to work in it. It may be kept open, but only for ventilation. The 1200-ft. level of the Alpha, which is connected with the Giroux shaft, is still in the oxidized zone, the ground being generally soft and difficult to hold. There are extensive bodies of ore of high grade, for this district (5 to 20%), exposed. From the surface indications east and north of the Alpha shaft large bodies of good-grade ore are expected when the sulphides are reached. On the east side of the hill from the Alpha, at the Old Glory, Morris No. 1 and 2, the Bunker Hill shafts and in their vicinity, the disseminated sulphides occur, in places within a few feet of the surface and to 150 ft. in depth over a considerable area and to a depth of 500 ft. in places. While at present ore is being hoisted from Morris No. 2 and Bunker Hill shafts, it is quite feasible to obtain a railroad level below the present Nevada Northern railroad tracks, and extract ore from both the Old Glory and Morris hills with steam-shovels; obtaining at least 200 ft. in depth of ore over a large area. This may be done later. At present an average of four carloads per day is being shipped from Morris No. 2 shaft to the Steptoe smelter. This ore averages about 3% copper. The arrangements at the Morris are only temporary. The ore is raised in mine-cars, run over tracks on surface to one side, and dumped into railroad cars. Consequently the tonnage cannot be materially increased from this shaft immediately. At the Bunker Hill shaft a raise has been made from the first level to the surface and into the old stock pile of ore in the dump said to be of good grade, up to 10%, but more or less oxidized. On May 26 the ore-bins were finished and a small skip placed, and hoisting the dump ore began. It will, from all appearances, be some time before the tonnage reaches 500 tons per day, the mine not being sufficiently prepared. Notwithstanding that the company had four months in which to get ready to fill the contract for 1000 tons per day, the mine and equipment are not yet ready. To draw off the powder-smoke and foul air three of the old churn-drill holes that connect with the Morris workings are being used, exhaust stoves being employed on the surface. There is no question but what the Giroux company has a great property; perhaps greater than the Nevada Con., but its development has been haphazard. With the deep-seated ores in the Alpha still in the oxidized zone on the 1200-ft. level on the porphyry-lime contact, and with over two miles of this contact on the property, it is too early to estimate the final value of the mine. To the north there are some iron gossan bodies radiating from the porphyry ores into the limestone and shale and varying from a few feet to 100 ft. in width. Sulphides may reasonably be expected under these. The Taylor shaft, 409 ft. deep, is about one-half mile north of the Giroux mill on one of the iron masses in the limestone area. The dump is said to average 9% copper. On June 1 the Steptoe smelter commenced to treat Giroux ores. W. G. Hawkins, of the engineering force, is there, representing the Giroux interests.

The Nevada Consolidated is drilling a hole adjoining the Liberty pit, for the Butte & Ely. It is reported that the ore will be mined with steam-shovels from the Liberty pit and treated by the Nevada Consolidated. This company is pursuing its usual systematic course. The 5-ton dippers of the 95-ton steam-shovels load a train of 20 cars, 55 tons each, in one hour. The ore is now coming from the west side of Eureka pit and the east side of Liberty pit, about 2000 ft. apart. The overburden in the latter has been 200 ft. deep and is a blocky silicious limestone. In the old Eureka pit the shovels are as deep as they can go, until such time as connections are made with the Liberty pit, when they will be able to circle and go deeper. It is claimed that there is 275 ft. of commercial ore below the present level of the bottom of Eureka pit. The only chance for a lower railroad level is across Ely Central ground, to the

north. An enormous amount of powder, said to be 20 cars per month, is used. It is handled mostly by foreigners. The greater portion of the laborers are of this class and many accidents occur. During last January exhaustive tests were made as to the relative efficiency of dynamite and black powder. The record showed that the average cost of breaking the ground with black powder per cubic yard was about one-half that with dynamite, or 6 $\frac{1}{8}$ ¢ and 12 $\frac{1}{2}$ ¢, respectively. The overburden and ore is not hard. Within the past few days shovel No. 2, in the southeast portion of Liberty pit, ran into a nice body of native copper ore of a very good grade. It was not noticed until several carloads had been thrown over the dump; then the Greeks were seen examining it. At the smelter advantage is being taken of the abundant water-supply and high price of copper. Last month 314,137 tons of ore was run down from the mines to smelter. Everything is being run to capacity. The traffic is so heavy on the railroad that the block system will be installed between the mine and smelter. There is a large amount of snow in the mountains, where the water-supply comes from, and with the completion of the new large settling-tanks there will be no further delay on account of shortage of water. Up to January 1, 1912, and for the 15 months previous, the average monthly production of the company was a little over 5,000,000 lb. of blister copper, at an average cost of a trifle over 7¢. per pound, including all costs and depreciation of plant. One month 7,000,000 lb. was produced at a cost of 6¢, this constituting the world's record. Only 70% of the value of the ore is saved. The average gold and silver content per ton of crude ore saved was 18¢. for the above period. Experiments are being made to find a way of making a closer saving on the slime.

The reorganization of the New Ely Central company has been completed, and the company is going ahead and developing its ground with churn-drills. Sulphide ore is being found on the Chispy claim at about 500 ft., in the drill-hole. James Jacoby, the manager, resigned June 1 to develop his own copper property, in Inyo county, California. R. T. Pierce, from California, succeeded him. Those who know Ely Central ground best are confident that under legitimate mining methods commercial ore will be opened. The Ely Consolidated company, at the Zaek shaft, has recently placed new pumps and boiler in order to sink 200 ft. deeper from the 600-ft. level. The Nevada Consolidated on this account has discontinued the pumping of about 250,000 gal. of water per day from the Zaek shaft.

The Copper Mines Co. is working a few men and opening some ore said to be 10%. The Smokey Development Co., whose property is just above Lane City near the old Chainman, which was worked for gold 30-odd years ago, intends to start work soon. It is claimed that a short adit can be run in from the gulch to reach sulphide ore. Only a short spur from the Nevada Northern would be necessary to give railroad connection. The stock has recently been listed on the Boston Curb. The Ely Verdi is an old company, and has recently altered its by-laws. It is not intended to commence development, there being no funds in the treasury, further than to do the annual assessment work. George Wingfield is one of the stockholders and a director. The present price of copper has led to inquiry for outside properties.

There are many claims in the district on which patent is held up by rulings of the Land Office. One engineering firm has upward of 60 claims on which receivers' receipts have been issued, but patent held up for want of sufficient mineral showing. The owners were given a short time in which to make this, or entry was to be cancelled. The claims being in the limestone, to make a real discovery means hundreds of feet of work. The ground itself is not worth 25¢. per acre for any other purpose. There is no water or timber and but little grass. The old debts of the U. S. Tungsten Co., recently examined for the Tonopah Mining Co. by J. E. Spurr, have been paid, and a contract for 200 ft. of work has been let. Colorado men were recently here examining the old Ward properties 18 miles south. There is a large tonnage of low-grade lead-silver ore blocked.

BUTTE, MONTANA

UNITED MINE WORKERS ORGANIZE.—BUTTE MINERS' UNION REFUSE OFFER OF ANACONDA COMPANY.—FUNDS FOR BUTTE BALLAKLAVA-ANACONDA SUIT.—STEWART RECEIVERSHIP CASE.

The United Mine Workers of America are organizing throughout the Northwest. A few days ago delegates met in this city and formed the Rocky Mountain association of this organization, taking in the following districts: Montana, Wyoming, Washington, Colorado, Utah, and New Mexico, together with Vancouver Island and British Columbia. A committee appointed to set forth the objects of the association reported. "The most important thing this organization will persistently and insistently advocate will be the negotiation of wage agreements, covering wages, hours of labor, and working conditions, at one and the same time by all the coal producing states belonging to the association." It is pointed out that coal mining is a hazardous occupation in the extreme owing to natural conditions, and there has been lack of attention to life-saving. The efforts of the organization were pledged to secure better conditions for men who work around coal mines. The association will meet annually. Officers were selected and an effort is to be made to enroll in the organization every man engaged in and around coal mines. During the next twelve months steps will be taken to secure the enactment of a law in every state looking to compensation for injuries received while at work.

At the present time the miners in the Butte district are paid \$3.50 per day, and a committee of the Butte miners' union was appointed some time ago to ask for an increase to \$4. After several conferences with representatives of the Anaconda company they reported that the company was willing to pay \$3.75 per day while copper was selling between 15½ and 17c. per pound and when the metal advanced above 17c. the wages would be \$4 per day. To the surprise of everyone the miners rejected the proposal, and today they are working for \$3.50, while if the offer had been accepted they would be receiving at least \$3.75 per day. The common understanding is that the offer of the increase was rejected because the Socialists, who secured possession of the hall, were in the vast majority in the meeting and refused to accept the increase. The Socialists hoped to place the company in an unfavorable position and bring about trouble. In this they will not be successful, for the conservative element is in the great majority in the union, and before any action can be taken looking to a further demand a referendum vote will be called by the new set of officers just elected, and the offer of \$3.75 is expected to be accepted. It was clearly demonstrated a few months ago when the full membership got an opportunity to vote, that the Socialist element was in the minority, so that there is no danger of any trouble over the wage question.

None of the Boston stockholders of the Parrot company, who are endeavoring to have set aside the sale of the property to the Anaconda company, were present at the annual meeting held at the offices in this city a few days ago. The only business transacted was the election of the same directors as last year, with the exception that C. F. Kelley takes the place of the late F. P. Addicks. The only asset of the Parrot company is 90,000 shares of Anaconda stock which was received in payment for the property.

The Butte-Ballaklava company has secured \$100,000 from John G. Williams, giving a mortgage on the property as security. In a statement it is announced that the money is to be used in fighting the suit brought by the Anaconda company for the recovery of a large amount of money as value for ore alleged to have been extracted from ground claimed by the Anaconda company. The company is carrying on development on the 1600-ft. level and is shipping a small amount of ore each week. The point where the work is now proceeding is outside of the ground in dispute. P. H. Nelson, who recently retired from the presidency of the company and has been succeeded by George C. Swallow of Milwaukee, found that he could not further devote his time

to the direction of affairs. Mr. Swallow is expected in the city in a short time to look over the property.

A semi-official statement of the condition of the affairs of the Stewart company has been issued, in view of the application for the appointment of a receiver by one of the directors. It is stated that during the first four months of the year the net earnings were \$126,000, after deductions of \$10,000 to \$20,000 per month for equipment and development. In the application for the receiver it was stated that Mr. Heinze gave to H. U. Hart, of New York, 225,000 shares of stock for which nothing had been received. It is now stated that the stock was given to Mr. Hart for his services in driving the recently completed Fir adit after his efforts to make arrangements with the neighboring Coeur d'Alene Development Co. for the use of one of its adits had failed. Through his influence there was acquired by the Stewart company a one-third interest in the Coeur d'Alene company and he also negotiated the smelting contract with the Guggenheims.

JOHANNESBURG, TRANSVAAL

FAR EAST RAND.—BRAKPAN SHOWS PROFIT.—APEX AND OTHER PROPERTIES ENCOURAGING.

Attention is now being attracted to the improved prospects of the Far East Rand. Despite somewhat discouraging bore-hole results, the Consolidated Mines Selection Co., Ltd., some years ago took the Brakpan property and sunk two 7-compartment shafts to the reef and were rewarded by finding profitable orebodies. Over a million sterling has been spent up to the present in connection with this undertaking and today the mine is earning profits in the neighborhood of £30,000. Another mine which has also assisted to bring about a change of opinion with regard to the prospects of the Far East Rand is the Modderfontein B mine, which is an outcrop mine where an expenditure of three-quarters of a million sterling can point to equally good results as those attained at Brakpan. The working costs may be somewhat higher than the average for the whole of the Rand, while the profits are nearly double those of the Rand average and decidedly higher than the profits per ton at the neighboring mines. The Van Ryn Deep is opening so well that no difficulty seems to have been experienced in obtaining the capital necessary for its equipment. Even Geduld, which in the early days of its history was responsible for the unduly high and inflated opinions formed regarding the prospects of the neighborhood, is at last showing signs of improvement and thereby causing the prospects of other deep-level developing properties to be regarded with increased favor.

There have, however, been several disappointments experienced in the Far East Rand, some, such as the Geduld, for instance, are difficult to understand and explain, while others, such as at Cloverfield and Van Dyk, are due to lack of adequate capital, and an enterprising control. A striking example of enterprise under adverse prospects is afforded by the Apex gold property, where, after twenty years of boring and shaft-sinking in search of a profitable stretch of reef, ore has at last been found. At the end of March nearly 400,000 tons of profitable ore had been developed on the Apex showing a milling value of 6.45 dwt. over a width of 53 in., and with the proposed merging, or rather absorption, of the adjoining unfortunately handled Benoni concern, the mining prospects of the Apex gold section, disregarding the Benoni debt, will be roughly doubled in value. No gold has as yet been recovered from the Apex.

Taken on the whole, the successes on the Far East Rand will far outnumber the failures and the doubt thrown upon the value of this part of the Rand by irresponsible persons has not been justified either on geological grounds or by actual mining results. Today the Far East Rand may be safely regarded as of far more value than any similar stretch of country on the western part of the Rand or of equal value at least to that proved between Germiston and Boksburg. The few disappointments caused have been due to oversanguine expectations or to want of ordinary enterprise and efficient handling.

General Mining News

ALASKA

ALASKA PENINSULA

(Telegraphic Correspondence.)—A heavy eruption of the Katmai volcano has destroyed the fishing villages on the Alaska peninsula, and on Kodiak island. Several inches of ashes have fallen on the mainland in the neighborhood of the volcano, and on the east side of the island. The United States revenue cutter *Manning* has reported by wireless from Kodiak harbor that there has been no loss of life on the island, but that the inhabitants are destitute, as their homes were destroyed by a storm of ashes and sand which began on June 6 and kept up for two days. Heavy earthquakes are also reported from the neighborhood of the eruption.

Cordova, June 12.

COOK'S INLET

(Special Correspondence.)—The Gold Bullion Mining Co. is working its property on Crazy creek, in the Willow creek district. An adit is being driven to cut an orebody which in an upper level yielded \$1600 per day for a five-days run with a 7-stamp mill. The old mill building was torn down and a new building with blacksmith and workshops built. Six ore-bins will be completed by June 15. Cal Johnson has directed the work this spring as superintendent. William Barthoff, manager for the company, is expected from Seattle in June. The Alaska Gold Quartz M. Co. is operating its claims on Fishhook creek. This property has a 3-stamp mill and one new Nissen stamp was freighted in over the snow last winter. Other claims will be developed as soon as pack trains can get into the district. The Alaska Free Gold M. Co. has leased its property to Mr. Martin, who is planning to operate the mine next winter. The wagon-road to Fishhook creek has been repaired, and a Lane mill, with boiler, engine, and complete supplies will be brought in for the Free Gold company.

Knik, May 24.

ARIZONA

GILA COUNTY

(Special Correspondence.)—The May production of the Old Dominion smelter amounted to 2,160,000 lb. of fine copper, about the same rate as for the previous month. There will be no attempt to meet the prevailing price of copper with increased production until after the capacity of the concentrator has been increased and other improvements made. An average of $2\frac{1}{2}$ furnaces were in operation during the month. The foundations are in for the new flue and dust-chamber at the converter plant, and the steel has been shipped. Plans are now being worked out for hoisting the ore in skips instead of cages, the change to be made without interfering with hoisting or in any way curtailing production. H. Kenyon Burch is working on the plans for doubling the capacity of the concentrator. An important metallurgical change to be made in the near future is the use of basic instead of acid lining in the converters. An order is placed with the Power & Mining Machinery Co. for a large converter stand and two shells that will take the place of the three small stands now in use. It will be of the Great Falls type and electrically operated. About 1150 men are employed at present.

The Miami company produced in May about 2,700,000 lb. of copper, a slight increase over the April production. A large amount of development is being done, the amount for May totaling 5627 ft. Work is about to start on the construction and equipment of a new machine-shop near No. 4 shaft, and the foundation is in for a second 500,000-gal. mill-water supply tank. The mill is now using nearly 2,000,000 gal. of water per day. About 900 men are employed, of whom 500 work underground.

A petition is being signed by prospectors, claim-owners, and business men of the Globe-Miami district addressed to the Arizona legislature, now in special session, asking

that the miners' lien law recently enacted shall be amended. The law as passed provides that persons furnishing labor, or material to be used in mines or on mining claims, under contract with the owners or their agents, or with lessees, or with persons or corporations working the mine or mining claims under option to purchase, shall have a lien upon such mine or mining claims for such sums as are unpaid. In other words, prospectors and claim-owners will have to stand for any debts contracted by individuals or corporations working their claims under option. It is generally believed that the enforcement of such a law would mean stagnation, if not paralysis, to the development of mines and prospects in Arizona. While it is admitted that the law affords admirable protection to miner and laborer, for which purpose it was intended, yet it is believed to be grossly unfair to the small claim-owner and prospector.

Activity is displayed in the old silver camps in the Apache mountains, about 12 miles northeast of Globe. The old McMorris mine in Richmond basin, a producer of rich silver ore in the late seventies and as late as 1882, is being reopened by W. D. Fisk of Globe and associates. A new gasoline hoist has been placed and the 800-ft. shaft has been retimbered for a depth of 160 ft. George Wilson is superintendent. John Mitchell and Ed Casson are working Fred Hefty's group of 12 claims under bond and lease. These claims adjoin those of the McMillen-Stonewall company. The Rice brothers are developing the Buckeye group and Lee Ikenberry is taking high-grade silver ore from his claims in Richmond basin. Ed Simonton is mining high-grade silver ore on the claims of P. W. Gallentine, on which he has a lease. No sensational discoveries are being reported, yet some high-grade silver ore is being mined, and honest efforts are being made to develop this once-famous district.

Charles H. Moyer, president of the Western Federation of Miners, has concluded a two-days visit to Globe and Miami and left for Phoenix, whence he will return to Denver. Mr. Moyer said his visit had no especial significance, but that he was merely paying a visit to the local unions.

After a conference of the managers and superintendents of all the principal mines of the Globe-Miami district, an increase of wages or reduction of hours has been granted to all employees, to take effect June 10. Nearly 3000 men will be affected. The nine-hour day has been abolished for surface men and hereafter all employees on surface and underground will work not more than eight hours per day. All surface men who have been working eight hours per day will receive a 7% increase in wages. Surface men working nine hours will receive the same pay for eight hours work. All men working underground will receive the same pay as heretofore, but will spend a total of only eight hours underground, as provided in the eight-hour law recently passed by the legislature. The men will be hoisted and lowered and will eat their lunch in this eight-hour period, which will consume about an hour; so they will hereafter receive the same pay for seven hours work that they have been getting for eight. The increase is in line with the policy of the large mining companies adopted several years ago of granting an increase in wages when copper shall have advanced in price beyond a certain point, with the understanding that they shall be lowered to the old rate when the price of copper falls below that point. This 'critical point' was fixed at 18c. in Butte and seems to be established at 16c. in Arizona. The companies state in the notices posted at the mines that they regret that the wages of underground men cannot be increased, but the eight-hour law reducing the actual working time to about seven hours prevents this, as it is not possible to reduce working hours and increase wages at the same time.

Globe, June 5.

PIMA COUNTY

The Pioneer smelter has shipped three carloads of matte valued at \$20,000 to the El Paso smelter. The Twin Buttes and Patagonia districts are now supplying the Pioneer with all the ore it can treat.

CALIFORNIA**AMADOR COUNTY**

(Special Correspondence.)—The Pacific shaft of the Plymouth Consolidated Mining Co. has been unwatered to a depth of 1150 ft., and the timber found to be in fairly good condition. The 950-ft. level has not caved since the mine was shut down twenty years ago. In the 1065-ft. level a cave was found 20 ft. from the shaft. At present the air in the 1140-ft. level is so bad that no attempt has been made to go into this level. About 300,000 gal. of water is hoisted from the mine every day.

Plymouth, June 11.

At the Gold Cliff mine the caving of a bluff on the afternoon of June 9 buried the electric motor, wrecked the hoisting engine, damaged the building, and deposited about 1000 tons of rock and earth in the shaft. No one was injured, as the hoisting engineer was outside the building and the other men were oiling the skips. The damage will amount to several thousand dollars and operations will be suspended for a week, until the shaft is cleared and repairs made.

The concentrator of the Calaveras Copper Co. commenced operations last week. The management expects to blow in its own smelter in August, but in the meantime high-grade ore will be shipped to the Campo Seco plant.

ELDORADO COUNTY

The Northern Ontario Exploration Co., Ltd., a Bewick-Moreing company, has taken an option on the Beebe property at Georgetown, and has begun active development. This is a new prospect recently discovered and interesting as showing that there are veins of value still to be explored in the Mother Lode region.

MARIPOSA COUNTY

The Original M. & M. Co. at Clearinghouse is just completing the erection of a Joshua Hendy 10-stamp mill. The ore is free milling, and the company expects to make

CHAMPION MILL, GRASS VALLEY.

a good recovery on the amalgam plates. The Original owns its own hydro-electric plant and develops power from the Merced river by the use of low-head turbines and Westinghouse generators.

MODOC COUNTY

A test of the persistence of the veins exposed at the surface at High Grade will be made by J. F. Cutler. Mr. Cutler has purchased from the Joshua Hendy company a steam hoist, and has announced that a shaft will be sunk 500 ft. as soon as this hoist can be shipped into the district.

NEVADA COUNTY

The Champion mill resumed operations June 6 with 20 stamps dropping. Development ore from the 1600-ft. drift of the Merrifield shaft is supplying the ore. The mill has been idle since the North Star Mines Co. took hold of the property, but \$200,000 has been spent in the past few months in unwatering the mine and in development. Only 30 ft. of water remains to be raised, and the 2400-ft. shaft will be free of water. Drifts will then be run on the vein at the bottom.

The Bald Mountain Gold Mining Co. filed articles of incorporation in Nevada City recently, with J. E. Hippert, W. H. Hippert, John Hippert, Sr., Samuel Hirsch,

and A. C. Travis as incorporators. The company was formed for the purpose of mining quartz and gravel claims above Graniteville. During the past year the owners of these claims have driven a long adit to tap a gravel channel, and this adit cut through several quartz veins. The new company intends to thoroughly prospect its property.

PLUMAS COUNTY

The California-Utah Gold & Copper Co. was recently organized in Salt Lake City for the purpose of operating claims about 11 miles from Doyle, on the Western Pacific railroad. A vein can be traced for 3000 ft. on the surface across the property. In the bottom of a 50-ft. shaft samples have been taken which assayed 4% copper and from \$2 to \$6 in gold.

SHASTA COUNTY

The Hazel G. M. Co. has started to sink the shaft on the Gladstone mine 300 ft. deeper from the ninth level. The mine is opened by an adit 3600 ft. long, and the deepened shaft will be about 2000 ft. below the apex of the vein. A 150-hp. double-drum electric hoist raises the ore to the adit, where it is handled by a modern electric haulage system using 220-volt alternating-current motors. At the mill 30 stamps are dropping, crushing an average of 100 tons per day. The company owns a hydro-electric plant for supplying power to the mill and mine.

The Pittsburg & Mt. Shasta G. M. & M. Co. is operating the Little Nettie mine near Keswick. The mine is developed by an adit, and a shaft which has been sunk 300 ft. below the adit-level. At present a 15-stamp mill is in operation, but T. V. Scott, manager for the company, has gone to Pittsburg to attend a stockholders meeting, and to take up the question of additional improvements with a view to increasing the output of the mine.

The electric smelter at Heroult, owned by the Noble Electric Steel Co., is producing pitch, tar, acetic acid, and wood alcohol in quantity. These substances are obtained as by-products, extracted from wood in the manufacture of charcoal for use in the smelter. Recently a carload of pitch, a carload of lime, a carload of tar, and a carload of pig iron were shipped to San Francisco. After a 35-day run the smelter has been shut down and new electrodes will be put in the furnace. This will more than double the capacity of the smelter, as 2600 hp. of electricity will be available, instead of 1200 used in the furnace up to this time. Several carloads of pig iron are stacked up in the yard ready for shipment as soon as cars are available.

COLORADO**PITKIN COUNTY**

*The Smuggler mine has been closed by a refusal of the timbermen to accept a cut in wages from \$3.50 to \$3 per day. The company works two 8-hour shifts per day and employs 18 timbermen, who work in squads of two each. In order to curtail expenses the management attempted to make one of the two men in each squad a helper and reduce his wages to \$3 for 8 hours. Only enough men are working at the mine to keep water out of the workings. The miners' union has been reorganized in this district.

TELLER COUNTY (CRIPPLE CREEK)

At the Portland No. 2 shaft-sinking from the 1500-ft. level was started June 3. The company plans to sink an additional 100 ft., and develop the main orebodies to greater depth. On the 1500-ft. level two machines are breaking ore, but little is being done in the way of development. The Portland stopes are being filled with sand from the mills, and in future mining, instead of short stopes made on individual orebodies, the stopes will take in everything, including the low-grade ore between ore-shoots, and all ore will be put through the Victor mill of the company. The Blue Bird shaft, on Bull hill, is now the deepest in Cripple Creek. The sinking has been going on for weeks and is now at a depth of 1714 ft., where it is believed the water-level has been encountered. The output from the Blue Bird is regular and amounts to two or three cars of good ore per week.

The stock of the El Paso Gold Mining Co. has been boomed recently by the sale of 400,000 shares at 90c. per share to a party of Swiss bankers. The El Paso has shipped since March, 37 cars of ore averaging \$105 per ton. So far the El Paso mine is the only one in the district which has been helped by the Roosevelt drainage tunnel, as all the ore shipped has been produced below the old water-level. A 400-ton mill to cost \$475,000 is contemplated by the management, as there is now about 900,000 tons of \$6 ore on the dump and about 200 tons is hoisted every day. The Roosevelt tunnel is now discharging about 12,000 gal. of water per minute. The average drop in the general water-level is from 10 to 15 ft. per month, and the total subsidence since the tunnel reached the El Paso shaft is 152 ft. The cost of lowering the water by pumping is estimated at \$5000 per foot, and the eventual saving which will be made by the Roosevelt tunnel is figured at \$3,500,000.

IDAHO

COEUR D'ALENE

The Iron Mask Mining Co., operating a group of claims at Carter, has issued a report on the development accomplished in the year ended April 30, 1912. The cost of driving an adit 1020 ft. was \$7.29 per foot. Deducting the cost of track material, pipe, and fittings, the cost of labor, explosives, candles, and power was \$5.53, which the company claims as a record for the district. This adit has cut a wide vein, from which some shipping ore has been taken.

The Federal Mining & Smelting Co. is producing about 4000 tons of lead and 200,000 oz. of silver per month. The chief problem of the company is the handling of the low-grade refractory ores from the Mace and Morning mines. No report has been received from Thomas A. Edison, who has been conducting experiments for the company. The second unit of the tube concentrating plant is ready for operation. The first unit has been making \$8000 per month. At the present price of lead and silver the gross sales of the company amount to \$440,000 per month, of which about \$75 is net profit. The tons of ore mined, the net earnings, and the net earnings per ton of ore mined since 1905 are as follows:

	Tons ore mined.	Net earnings.	Net per ton ore.
1905	664,830	\$1,242,679	\$1.78
1906	974,332	2,685,300	2.70
1907	888,950	2,532,250	2.85
1908	599,850	1,067,036	1.78
1909	832,568	1,185,946	1.42
1910	741,650	944,706	1.27
1911	784,600	1,280,285	1.63

SHOSHONE COUNTY

The new concentrator of the Snowstorm Mining Co. is reported to be working successfully. The first car of copper concentrate has been loaded, and this shipping product is said to be 20% copper and 30 oz. of silver per ton. The mill has a capacity of 100 tons per day, but units may be added if it is desired at any time to increase the output.

MONTANA

MADISON COUNTY

The California Placer Mining Co. is having a survey of its claims made. They comprise about 5000 acres north-east of Virginia City. It is thought that the original bed of Alder creek was through this property, and the management is planning to prospect the ground with Keystone drills to a depth of from 100 to 400 ft. W. B. McCublen, of San Francisco, and B. L. McCoy, G. E. Egbert, and B. N. Paxton, of Oroville, are among those interested in the company.

SILVERBOW COUNTY

The annual report of the Amalgamated Copper Co. for the fiscal year ended April 30, gives the net profits of the year as \$6,647,006, equal to 4.31% on the outstanding stock, as compared with 3.93% for the preceding year. Dividends to the amount of \$3,847,197 were paid, and the surplus increased to \$21,252,201. Work is being done at

all the important mines in the Anaconda group with a view to increased output at lower costs. At the Leonard mine, the hoist has been changed over for the use of air, and at the Tramway and West Colusa the cylinders are now being changed. Electric haulage will be in operation on all the main levels in a few months, and by September 1 the lower levels of the mines will be connected by crosscuts with the Belmont, which will then be the main hoisting shaft of the group. The central compressed-air plant has been completed, and is operating six compressors, each with a capacity of 7500 cu. ft. of free air per minute. As the power consumed is intermittent, sufficient power is thus generated to operate all the larger hoists. The copper production for May from Butte was 29,082,362 lb., from 433,046 tons of ore.

NEVADA

NYE COUNTY

The White Caps mine has completed its first run of 1000 tons of ore at the Associated mill, and has replenished the dump by hoisting every night from the stopes. A new body of low-grade ore has been found in the east drift 400 ft. from the shaft.

The sixth annual report of the Round Mountain Mining Co., for the year ended March 31, gives the ore reserves at 145,820 tons, an increase of 33,892 from the preceding year. The mill treated 54,915 tons with a gross value of \$7.09 per ton and recovered 88%, or \$6.24 per ton. Operating costs for the year were \$4.96 per ton, including a depreciation charge of 31c. per ton and 20c. per ton to cover litigation expense. The net realization was \$1.36 per ton, or \$74,830. Additions were made to the mill, the mine office, the underground crushing plant, and a complete fire-protection system, at a cost of \$34,000. The mining costs were reduced from \$6.02 for the preceding year to \$4.88, and the report states that a further reduction will be made. New development amounted to 7508 ft., at a cost of \$6.60 per foot, equal to 90c. per ton of ore milled, or 56c. per ton of new ore developed. During the year the company received the sum of \$4202 in royalties from lessees working placer ground on the company's property. It is expected that the litigation in which the company has been involved will reach a settlement within a short time.

The shaft of the Halifax-Tonopah Mining Co. is now nearly 1300 ft. deep. At a depth of 1275 ft. a contact was found with andesite above and rhyolite below. The bottom of the shaft is now entirely out of the rhyolite, and in quartz which is heavily stained with iron and shows specks of silver sulphide. The sinking of the shaft to this depth has been accomplished at a cost of \$47 per foot, and about \$90,000 has been expended on this work and surface equipment. A new and more powerful electric hoist has been ordered and plans are being drawn for a 120-ft. steel head-frame.

STOREY COUNTY

The tax statement for the first three months of 1912, filed by the Mexican Gold & Silver Mining Co., shows an output during that period of 5087 tons of ore. The gross yield on the ore milled was 51,579.78 and the cost of extraction was \$40,986.11. The cost of transportation was \$2352.88. The cost of reduction and sale was \$15,196.78, and \$10,393.73 was expended for mill construction. This report brings the total bullion production for the Comstock district for the first three months of 1912 to between \$225,000 and \$250,000.

WHITE PINE COUNTY

A new chimney is to be built at the Steptoe smelter to replace the one now in use. The old stack, 250 ft. high, with an inside diameter of 18 ft., is cracked badly. The wooden trestle over which the ore is brought to the concentrator will be replaced by a steel structure. These are the first important renewals to be made since the Steptoe plant was started in 1907.

May was a record month in the amount of ore handled by the Nevada Northern railroad from the mines of the Steptoe works of McGill. During the month 314,137 tons

of ore was shipped from the big pit and transported over the high line, a daily average of 10,133 tons. The best previous month was July 1911, when 293,551 tons was moved.

NEW MEXICO

SANTA FE COUNTY

The Santa Fe Gold & Copper Mining Co., which closed its mine in New Mexico in October 1907 because of inability to continue to work the property on a profitable basis, has resumed active operations, now that the price of copper has made a large advance. The company has built a 20-mile branch from its mine to a connection with the Santa Fé railroad.

SOCORRO COUNTY

The Ernestine M. Co. output for May was 34,920 oz. gold and silver bullion and 36,550 lb. of high-grade concentrate. At the Socorro mines approximately 45,000 oz. gold and silver bullion and 25 tons of concentrate were produced in May.

OREGON

JOSEPHINE COUNTY

The Tennessee Gulch mine has been sold by Hasselton & Wagner to Portland people for a price said to be \$40,000. This is an old mine which was worked by ground sluicing; recently three veins have been found which show promise. J. O. Gunn has shipped the fourth carload of

SALT LAKE COUNTY

The report of the Ohio copper company for the six months ended March 31 was given out at the annual meeting of the company held at Portland, Maine, on June 5. The ore mined in this period amounted to 311,068 tons, and the copper produced was 3,754,866 lb. The ore averaged 1.176% copper, and apparently the recovery was 50% of the copper content. The average cost of mining was 26.73c. per ton of dry ore and the milling cost was 37.02c. per ton. The total operating expense was \$251,050, and the operating profit \$184,346. Miscellaneous expenses to the amount of \$74,869 brought down the net profit to \$109,477. This profit was used to equip the third section of the mill, and the company expects to treat 3000 tons per day by August 1. The report gives the mine 3,200,000 tons of developed ore in sight, and estimates between 9,000,000 and 10,000,000 tons of probable ore. The floating debt of the company has increased from \$588,979, two years ago, to \$839,489, but the cash on hand has also increased in the same period from \$8840 to \$120,043. The company has not been successful in marketing its bonds, of which there are in the treasury \$754,000.

SUMMIT COUNTY

The Daly-Judge mine has opened up the Daly vein on the 500-ft. level, and George W. Lambourne, manager for the company, hopes development will prove this level

COPPER SMELTING PLANT, INTERNATIONAL S. & R. CO.

ore from his mine near Takelma to the smelter at Kennett. At the Iron Crown, 11 miles from Grants Pass, copper ore, from 1 to 17% copper and \$5.50 to \$8 per ton in gold, has been found.

UTAH

JUAB COUNTY

The May Day M. & M. Co. has made a contract to ship zinc ores to smelter at Bartlesville, Oklahoma, and has cleared the chutes in the mine of other ores in preparation for the loading of several carloads of zinc ore. It is estimated that 1000 tons of ore carrying 40% zinc is stored in the stopes.

The Yankee Consolidated Mining Co. has levied an assessment of 2c. per share, in order to continue development. A statement sent out by the directors explains that the shaft has been sunk to a depth of 2000 ft. and that cross-cuts driven from the 1800 and 1900-ft. levels found large mineral zones with small seams of ore. A large part of the development to date has been paid for by the sale of a large dump of low-grade ore. This is now practically all shipped, and additional funds for exploration must be raised by assessments.

A tabulation of the ore shipments from the Tintie district shows that between January 1 and May 10, 3265 cars of ore, worth \$2,612,000, were shipped from the district.

as productive as lower stopes. The vein was first extensively opened on the 1200-ft. level and later on the 900. On the 700-ft. level the vein has made some big stopes and development at that depth gave indication of the extension of the ore upward in paying quantities. Ore was first found on the 700-ft. level over the No. 2 stope last September, and from that time to January 1, 1912, some 5000 tons of milling ore was taken out. Below this level the vein widened and the stope was found to be 40 ft. wide. Recent development on this level has indicated that good ore will be found above, and when the drift has progressed to the vein, it is believed that it will be found to be ore-bearing from the 500 to the 1200-ft. levels.

The Daly West Mining Co. has announced that milling operations will be resumed June 10. Enough milling ore is stored in the stopes to keep the plant busy for months, but only one shift will be put at work until an increased output seems desirable. During the past months the mill has been down on account of the freezing of the water-supply in the Wasatch range. Shipments of high-grade ore have been kept up, however, and good ore has been developed on six levels, the deepest of which is the 2100-ft. level.

TOOELE COUNTY

The International Smelting & Refining Co., in the year ended December 31, 1911, earned a gross income of \$3,539,-

204, and a net income of \$1,219,037. This is equal to 12.19% on the capital stock, as compared with 10.02% in 1910. Dividends to the amount of \$800,000 were paid, and the surplus of the company was increased to \$1,555,940. These figures are from the annual report published in New York and cover the operations of the company at the Eastern refinery as well as at the Tooele smelter. A recent order has been placed for four additional sintering machines for the Tooele plant. These will take care of the increased amounts of lead ore coming to the smelter for reduction. A bag-house will soon be erected in connection with the converter department.

CANADA

BRITISH COLUMBIA

The Windfall group of claims near Hedley has been bonded to the Hedley Gold Mining Co., the owners of the adjoining Nickel Plate group, which has produced about \$1,000,000 for this company. The price involved in the purchase of the Windfall is \$150,000.

The management of the Granby Con. M. S. & P. Co. will delay the building of the proposed smelter at the Hidden Creek property for three or four months, until it can prove by actual underground working the results of the diamond-drilling, which have indicated a large body of 2% self-fluxing ore. The management expects to build a 2000-ton plant, and the directors have voted \$300,000 for preliminary work, including foundation work, and also \$200,000 for mine development.

ONTARIO

From the Cobalt district the bullion shipments for the first five months of 1912 are as follows:

	Ounces.	Value.
Nipissing	1,587,763.75	\$920,892.18
Crown Reserve	207,203.00	115,951.19
Temiskaming	56,833.00	33,804.96
O'Brien	88,433.01	50,964.00
Nova Scotia	49,010.00	31,800.00
Buffalo	38,938.00	22,714.54
McKinley-Darragh	10,327.00	6,069.37
Kerr Lake	7,240.25	4,381.21
Trethewey	5,703.66	3,238.00
City of Cobalt	1,618.40	1,000.00
Colonial	1,698.00	1,018.00
Miscellaneous	16,268.81	10,798.64
Totals	2,071,036.88	\$1,202,632.09

The May shipments of high-grade ore are given, in pounds, below:

Kerr Lake	101,541
Temiskaming	395,329
Drummond	37,112
Beaver	111,094
Hudson Bay	125,493
Buffalo	182,482
Cobalt Townsite	310,335
McKinley-Darragh	440,753
La Rose	818,091
Coniagas	344,690
Nipissing	393,356
Chambers-Ferland	128,000
Crown Reserve	77,910
O'Brien	127,923
Trethewey	114,737
Colonial	43,200
Cobalt Lake	62,310
Total	3,814,356

A meeting of the Porcupine branch of the Canadian Mining Institute was held at the Pearl Lake Gold Mines bungalow, June 8. Starting of the Vipond mill has been delayed by the non-arrival of an electric motor which went astray. The other machinery is in place and ready for operation. In the mine ore has been broken and stored in the stopes, and it is the intention of the management to keep a

reserve of broken ore in the mine. The feed to the mill will be kept as uniform as possible and the underground reserves will be used to grade the ore to about \$15 per ton.

The reorganization of the Pearl Lake Mining Co. places the control of the company in the hands of officials of the Pennsylvania railroad, who are also connected with the Tonopah-Belmont in Nevada. The management of the Pearl Lake will be in the hands of the Hargraves Engineering Co. A development fund of \$250,000 has been raised and placed in the treasury. A 10-stamp mill will be erected immediately, so designed that additional stamps can be added if necessary. The main shaft, which is now down 400 ft., will be continued to the 800-ft. level, when another station will be cut, and a cross-cut started south to cut an ore-zone, which gave favorable assays from drill-hole samples last fall. At the 400-ft. level a cross-cut, which was started just before the old company made an assignment, will be continued 200 ft. to tap another vein which gave an assay of \$58 from the diamond-drill cores.

YUKON

The first steamer of the year left White Horse for Dawson on May 31. The Yukon river was then open for its full length. This is exceptionally early.

MEXICO

CHIHUAHUA

At the El Chochen mine near Temosachic, a new power plant is being erected, and the mine has supplies on hand to enable a steady output to be maintained.

DURANGO

(Special Correspondence.)—The Penoles Mining Co. has been granted a sixty-day extension from May 1, on its option on the Paloma mines in Mapami district. The original option was for thirty days, and during that period five engineers representing the Penoles company started an examination of the property. Their report was not ready at the time the first option period expired, and the extension was granted in order that the prospective purchasing company might have information in regard to the probable production of the Paloma mines. The proposed consideration is \$2,000,000. The Penoles Mining Co. is one of the strongest German mining concerns operating in Mexico. It has a capital stock of \$4,000,000 and its mines in 1911 paid a dividend of \$750,000 to the stockholders. It is expected that the Penoles company will extend development and increase production of the Paloma if the deal is made.

Monterey, June 10.

SONORA

The Greene-Cananea Copper Co. has recently acquired a large interest in a property known as the Sonora Bonanza, situated on the main line of the Southern Pacific in Mexico, south of Nogales, Arizona. The mine is said to produce ore averaging \$10 per ton in gold, but the chief value to Greene-Cananea is in the high percentage of silica in the ore. Greene-Cananea has been planning an increased output of approximately 9,000,000 lb. of copper per month, and has already placed three or four large converters. This increased production requires an additional amount of silicious material to treat with its iron ores, and the Sonora Bonanza is regarded as a valuable acquisition which will facilitate the desired metallurgical results.

A new company has been organized to operate the Abundancia property, formerly held under option by the Cananea West company and later by the Copper Queen company. The property is owned by Juan Cabral, Sr., and the new company, which will be known as the Abundancia Mining Co., has been organized by O. L. Neer, of Douglas, Arizona, and Apollis Fuller, of Boston. The property is six miles west of the Greene-Cananea smelter, on the west slope of the Cananea mountains. Some rich ore has been found in the past, and trial shipments were made to the El Paso smelter in 1908 and 1909. A force of men has been put at work, and shipments of ore will be made to the Cananea and Copper Queen smelters as soon as the mine can be reopened.

Personal

Professional men are invited to send news of their engagements and travels. Such news is interesting to friends.

LEONARD ORYNSKI is in San Francisco.

T. LANE CARTER is in northern Michigan.

GELASIO CAETANI has returned from Idaho.

PHILIP BRADLEY has gone to Nevada county.

WALTER HARVEY WEED is at Wallace, Idaho.

W. R. CRANE will leave for Alaska June 18.

W. A. WOLF is here from Ecuador for a short stay.

FRANK LAWRENCE is in San Francisco for a short stay.

ROGER BEALS has returned to San Francisco from Butte county.

R. B. NICKERSON has returned to Oakland from Kenora, Ontario.

H. W. YOUNG is leaving for a trip through British Columbia.

ALBERT BURCH was in San Francisco Monday, but left for Nevada Tuesday.

VICTOR G. HILLS is examining properties near White Horse, Yukon Territory.

R. S. BOTSFORD has returned to London from eastern Siberia, near Vladivostok.

WILLIAM H. KINNON is now manager of the S5 Mining Co., Lordsburg, New Mexico.

H. W. HARDINGE is in London and will visit Stockholm before returning to New York.

WILLIAM J. MCGEE has gone to Chicago and New York, expecting to return in about three months.

GEORGE WINGFIELD has been appointed United States Senator from Nevada to fill the unexpired term of GEORGE S. NIXON.

EDWIN J. COLLINS has returned to Duluth, Minnesota, from British Columbia, where he has been examining copper properties.

W. H. ALDRIDGE will make his headquarters after July 1 with WILLIAM B. THOMPSON, Bankers Trust building, 14 Wall street, New York.

E. S. SHEFFIELD has been appointed superintendent of the Empire and Pennsylvania mines at Grass Valley, California. GEORGE W. STARR continues as managing director.

Obituary

JAMES H. KINKEAD, inventor of the Kinkead mill and well known especially for his work on the Comstock Lode, died at Reno, Nevada, June 9, at the age of 69.

ALEXANDER HILL, of Alexander Hill & Stewart, died in London on April 24. According to 'Who's Who in Mining & Metallurgy,' Mr. Hill was educated at St. Andrew's and Glasgow universities. He entered the laboratory of the Tharsis Sulphur & Copper Co., then went to Rio Tinto mines, Spain, and was in charge of nearly half the works there for five years. From there he went to Mexico as manager of silver mines and reduction works at El Chico. Later he served as manager for Archibald Coates, of Paisley, Scotland, of various copper and other mines in Spain and Portugal. He became a partner of G. D. Delprat and in 1895 went to California for Matheson & Co. In 1897 he returned to England and in 1903 took into partnership C. H. Stewart, forming the firm of Alexander Hill & Stewart. Mr. Hill was about 55 years of age. His firm has been consulting engineers for the Le Roi No. 2, Ltd., with a group of mines and small concentrating plant at Rossland, B. C. From the time of the organization of the company in 1900, and in his consulting capacity, Mr. Hill visited Rossland several times, the last having been about five years ago. The firm has acted in like capacity for the Van-Roi Mining Co., with mines and concentrating mill in the Sloean district, British Columbia.

Book Reviews

Any of the books noticed in these columns are for sale by, or can be procured from, the MINING AND SCIENTIFIC PRESS.

A TEXT-BOOK OF RAND METALLURGICAL PRACTICE. Vol. I. By Ralph Stokes, J. E. Thomas, G. O. Smart, W. R. Dowling, H. A. White, E. H. Johnson, W. A. Caldecott, A. McA. Johnston, and C. O. Schmitt. Chas. Griffin & Co., London, 1912. For sale by the *Mining and Scientific Press*. Price \$6.50.

This important volume is so full of material that it is quite possible to approach it in review from a variety of standpoints. The authors are all men of prominence in the development of Rand metallurgy (the majority of them being or having been connected with the Consolidated Gold Fields of South Africa), and such a concerted effort could scarcely fail to be of great service and importance. W. A. Caldecott deserves especial prominence in the list of editors, since the production of this volume is largely due to his initiative and energy. The value and importance of such a work is obvious, and it would be easy to fill a large amount of space with commendation of its excellence. On the other hand, anything which is so good upon the whole can easily support criticism of its defects, and even on hasty reading it is evident that the book could have been much improved by the elimination of the obvious. The elementary material included sometimes verges on the absurd; on page 59 for example, "To reset a tappet it is raised on the stem, or the stem lowered through it." Rand metallurgists must be skeptical if they require to be assured that either method would be effective. Several of the co-authors appear to have forgotten the title of the work, and present general discussions rather than descriptions of Rand practice. This is especially so of the chapters on breaking and sorting, and assaying, both of which might have been greatly improved if their authors had chosen to eliminate the elemental and devote a corresponding amount of space to illustrations and records of Rand practice, with an analysis of the reasons for adoption and retention of the methods. Some of the chapters cause the reader to consult the date on the fly-leaf in bewilderment. Especially is this true of the chapter on stamp-milling, which also is disappointing because it is largely confined to a discussion of elementary principles rather than the features that characterize stamp-milling practice on the Rand. An analysis of the results of the recent comparison between individual mortar stamps and 5-stamp units would have been a most desirable feature, but the author has given us nothing on this subject. Apparently the old Challenge ore-feeders are still in use on the Rand, although the Nelson and other types of grip feeders have demonstrated their superiority in every other mining district in the world. The Challenge feeder with the old-style pawl, pawl-shoe, and 'banjo' friction is prominently displayed, while the Tulloch, superseded by the Challenge twenty years ago, is given a generous allotment of space. The reader is referred to Eggleston's 'Metallurgy of Gold, Silver, and Mercury,' which has been out of print for nearly two decades, while MacFarren's recent book is not even mentioned. Fig. 27 shows an "Improved" stamp-head, the improvement consisting of a hole cored longitudinally through the centre for the insertion of a drift-pin for the removal of the stem. This method was tried in California many years ago and abandoned because the hole weakened the casting, causing frequent breakages. The description of the new curve for cams, Fig. 23, developed by Hans Behr, is interesting but disappointing, as the author, while giving the radius of the curve, has neglected to show the relative position of the centre. We must disagree with the author's remarks on the order of drop. The salient point to be remembered is not that no two adjacent stamps must drop successively, but that the order of drop should be such that an even distribution of pulp between the shoes and dies should be obtained and the pulp should be prevented from banking in the ends of the mortar. The established drop that most nearly accomplishes this end

is 1-5-2-4-3, in which it will be noted that two stamps, 3 and 4, are adjacent and drop successively.

The chapter on assaying is likely to be a source of more astonishment than service to the ordinary assayer in America. The assay of ore containing free gold and assaying \$5 to \$6 per ton, by crushing the sample through a 60-mesh screen ("should, however, coarse particles of gold be liable to occur the screen must be inverted and any particles failing to pass be rubbed into the sample"), using 1 assay-ton charges, and weighing the gold on a balance sensitive to 0.02 mg., is at least a decade behind current American practice in assaying.

It is perhaps more of a compliment to the vigor of discussion among Rand engineers than criticism of the book that much recent material seems to have escaped inclusion in this volume. Some of the more valuable chapters have already appeared in print elsewhere, and the authors may have lacked opportunity to bring them up to date. The preparation of a volume by a multiplicity of authors, while having obvious advantages, presents no less obvious difficulties, and every such volume should have its lack of homogeneity viewed with toleration.

Those engaged in cyanide practice elsewhere will consult with the greatest interest the chapters on tube-milling, the treatment of sand and slime, and the chemistry of Rand ore-treatment. Considerations of space preclude any extended review of these, and it must suffice to say that they are discussed by men who are leaders in the work and are able, confining themselves to Rand practice, to present their topics lucidly and with authority. Not to attempt to catalogue its excellences, the beginning and end of the volume are especially admirable; namely, the comprehensive summary of the Rand and Rand problems, by Ralph Stokes, and that of the chemistry of Rand ore-treatment, by W. A. Caldecott. The tables which conclude the book, compiled by W. A. Caldecott and H. A. White, are unusual in containing so much of value in addition to the ordinary tabular material that can readily be obtained from any of the numerous handbooks. Altogether this volume is easily the most important of recent works on metallurgy and should be widely read.

MANUAL OF STYLE. The University of Chicago Press. Pp. 140 + 118; ill., index. Third Edition. Chicago, 1911. For sale by the *Mining and Scientific Press*. Price \$0.85 paper, \$1.12 cloth.

To engineers this useful book may perhaps be most easily described as a volume of specifications for the guidance of proof-readers, compositors, and editors. It is more than this, however, and the explanatory matter concerning the mechanical side of the printer's art will be of interest and service to all who have occasion to write for publication. In matters of detail the style of the *Manual* differs in many particulars from that of the *Mining and Scientific Press*, and the sentence at the bottom of page 36 was evidently not written by the professor of rhetoric at the University, but a consistent usage is most important, while uniformity can scarcely be expected before the Greek Kalends. The *Manual* is unusually comprehensive, and should be upon the reference shelf of every editorial room.

NEVADA STATE GAZETTEER AND BUSINESS DIRECTORY. Pp. 460. R. L. Polk & Co., Seattle, 1912. For sale by the *Mining and Scientific Press*. Price \$10.

This volume is a useful business directory and its lists of government and county officers, state boards and commissions, postmasters, postoffices, express, telephone, and telegraph offices, justices of the peace, hotels, and daily and weekly newspapers will prove of much service. Valuable data concerning all the principal communities, such as situation, population, distance to different points, the most convenient shipping points, products that are marketed, stage communication, schools, libraries, and societies form a feature of the work, and the classified directory of business houses, mines, and mining companies, and list of land owners compiled by county, giving postoffice address, is especially convenient.

Copper Statistics and the Copper Market

*In 1911 there was a decrease in the world stocks of 45,000 tons, leaving a little more than one month's supply on hand. German consumption increased 10%, and other European countries are using an increasing amount. American needs were less in 1911 than in the preceding year, by 5%, but there is promise of greatly increased demand from American consumers in 1912.

The large new supplies which were promised in fabulous quantities are not yet apparent. The first important consignment of copper from the much-famed Katanga district arrived about the end of the year, and it is manifest that problems have yet to be solved before a large production can be looked for from this source. In America also, a too optimistic view appears to have been taken of the time required to develop the new sources. The long-heralded vast quantities from the porphyry mines are still only futures. Similarly, the Braden Copper Co. in Chile, in spite of years of laborious development and the completion of its large smelters, has not yet entered the ranks of the producers. A further instance is furnished by the Copper River district in Alaska. The district has been spoken of for ten years as one of the richest fields in the world. It has been necessary, however, to construct a railway at great cost, and last year only about 7000 tons of ore found its way to smelters, and of this quantity only a portion could be treated in 1911. The next year should witness the completion of some of these prophecies. The Miami, Ray, and Chino will be large producers. Considerable quantities of copper from the Mason Valley company in Nevada and from the Chilean and Alaskan fields, may also be expected.

The world's copper production, according to the figures for 1911 compiled by Aron Hirsch & Sohn, is given in the following table, in tons of 2240 pounds:

Producing Countries	1903.	1906.	1910.	1911.
Germany	21,200	26,200	28,800	30,500
Austria-Hungary	1,300	1,500	2,250	2,520
Italy	3,100	3,100	3,000	3,000
Russia	10,300	10,000	22,300	25,500
Norway and Sweden	6,000	10,954	7,000	9,500
Spain and Portugal	49,700	51,000	53,000	55,000
Turkey	1,400	1,000	1,500	700
United States	311,500	417,400	482,200	487,300
Mexico	45,300	60,000	58,800	54,050
Canada	19,300	24,000	22,500	24,000
Chile	31,100	30,000	35,800	29,600
Peru	7,800	11,000	26,000	26,000
Bolivia	2,000	2,000	2,500	2,500
Cape Colony	5,200	8,500	7,000	7,000
Australia	29,000	43,000	43,400	44,600
Newfoundland	2,100	2,500	2,100	2,100
Japan	32,600	38,000	50,000	55,000
Miscellaneous	1,100	1,500	9,000	10,500
World's production	580,000	741,654	857,150	869,370

The world's copper consumption of the principal consuming countries, for the corresponding years, is as follows, in tons of 2240 pounds:

Consuming Countries.	1903.	1906.	1910.	1911.
Germany	116,318	163,098	208,826	234,985
France	52,789	68,927	92,838	106,408
England	110,765	121,256	148,187	159,736
Austria-Hungary	21,122	27,976	37,150	41,101
Russia	24,633	24,532	28,237	31,830
Italy	10,987	25,237	32,487	40,949
Belgium and Holland	8,600	12,798	14,000	13,000
Scandinavia	2,200	7,000	9,500	9,500
Rest of Europe	1,400	3,000	2,500	2,500
Europe	348,814	453,824	573,725	640,009
North America	241,071	316,964	334,565	316,791
Rest of America	1,200	2,200	3,000	3,000
Europe and America	591,085	772,988	911,290	959,800
China	4,605	2,576	5,000	4,500
Japan and rest of Asia	9,500	10,000	15,000	20,000
Africa and Australia	1,800	2,000	2,000	2,000
World's consumption	606,990	787,564	933,290	986,300

These figures do not show the exact proportion between the world's production and consumption, as in some cases the imports of manufactures have been included as consumption, although they have already appeared in the consumption total of the country of origin. The quantities of old metal, which are not separated statistically, also prevent an exact comparison.

*From 'Statistical Compilations About Copper,' issued by L. Vogelstein & Co., New York.

The world's stocks of copper on hand December 31 for the last four years is estimated as follows:

World's Stocks.	1908.	1909.	1910.	1911.
United States	54,624	63,289	54,480	39,937
England	40,961	95,673	66,917	42,104
France	5,266	6,299	6,080	5,254
Rotterdam and Hamburg ..	3,000	2,200	16,300	13,400
Total	103,851	167,461	143,777	100,695

The average price of copper since 1900 in the New York and London markets shows a wider range than can be accounted for by production and consumption tables. Evidently speculation, manipulation, and general business conditions have influenced price as much as the amount of stocks.

PRICES OF ELECTROLYTIC AND LAKE COPPER IN N. Y.

Av. Price in cents per lb.: Electrolytic, Lake.		Av. Price in cents per lb.: Electrolytic, Lake.	
1900	16.48	1906	19.39
1901	16.35	1907	20.11
1902	11.82	1908	13.22
1903	13.63	1909	13.02
1904	13.09	1910	12.81
1905	15.82	1911	12.47

On the other hand, the outlook is all in favor of an increase in European consumption, especially in Germany. The substitution of electric for steam power in railways is only a matter of time. Certainly a sudden transition is neither possible nor desirable, if only because of the gigantic amount of capital involved, and furthermore, a rapidly increased demand would be beyond the reach of production. American finances are sound, but disturbed by the impending election. After the settlement of this question, the state of industry in the United States should improve.

Copper consumption in America has not increased since 1906, and the natural industrial expansion impeded by the quiet years since then must be resumed with augmented vigor, and a boom period may be anticipated, when consumption gains by leaps and bounds, as in 1899 and 1905.

One further point of importance lies in the fact that no new mines have been exploited in the last two years, and in view of the low metal prices, there has been a suspension of pioneer work in this regard. There are, therefore, no apparent sources of new production, and even with new discoveries stimulated by better market conditions, new mines, as already shown, do not become producers for years, generally too late to profit by the high prices which induced their promoters to seek them. For a healthy development of the copper industry, exaggerated fear of overproduction on the one hand, and fevered activity, on the other, are equally harmful. Granted immunity from restraints of a political nature, the industrial world may look into the immediate future of the copper industry with confidence.

Dividends

The Daly-Judge has declared a dividend of 15c. per share, payable July 1.

Yukon Gold has declared a regular quarterly dividend of 1½%, payable June 29.

Old Dominion M. & S. Co. has declared a quarterly dividend of \$1.25 per share.

The Trethewey Silver-Cobalt Mine, Ltd., has declared a dividend of 10%, payable June 15.

The Montana-Tonopah Mining Co. has declared a dividend of 10c. per share, payable June 21.

Calumet & Arizona Mining Co. has declared a quarterly dividend of \$1 per share, payable June 24.

The Guggenheim Exploration Co. has declared a regular quarterly dividend of 2½%, payable July 1.

United Verde Copper Co. paid a dividend of 75c. on June 4, the fourth dividend during the current year.

The Hecla Mining Co. has paid its regular monthly dividend of 2c. per share, making a total to date of \$2,450,000.

Nipissing Mines Co. has declared a regular quarterly dividend of 5% and an extra dividend of 2½%, payable July 20.

The McKinley-Darragh-Savage Mines, Ltd., has declared a regular quarterly dividend of 3% and an extra dividend of 7%, payable July 1.

Decisions Relating to Mining

Specially reported for the MINING AND SCIENTIFIC PRESS.

OIL GRANT—RIGHT TO ERECT PUMPING STATION

Where a conveyance of oil and gas, with certain rights as to pipe-lines, conduits, and machinery in or upon the land of the grantor, is ambiguous as to the right to erect on the land pumping stations, the deed will be construed to give such right, where the grantee erected a pumping station on the land and operated it for fourteen years without objection from the grantor.

Collision v. Philadelphia Co., (Pennsylvania) 82 Atlantic, 474. Jan. 2, 1912.

GRANT OF MINERAL RIGHTS—TIME FOR COMMENCING WORK

Where a grantor conveys the mineral and timber rights on his land in consideration of certain royalties to be derived from developing such rights, the court will read into the contract the condition that development must be commenced within a reasonable time, if the contract contains no express terms as to the time of commencement. Failure to begin operations within such reasonable time will entitle the grantor to declare the rights abandoned and re-enter.

Eastern Kentucky Mineral, etc., Co. v. Swann-Day Lumber Co., (Kentucky) 146 Southwestern, 438. April 30, 1912.

MINER'S LIENS—LESSEE NOT THE LESSOR'S AGENT

Persons who furnished labor and materials for the development of a mine under contracts with a lessee in possession of the mine, with full knowledge that the lessee was operating under a lease, were held to have contracted with such lessee as principal and could not hold the lessor liable so as to charge his property with miner's liens. A mining lease containing the usual covenants does not constitute the lessee the lessor's agent with authority to contract for material and labor so as to charge the property with miner's liens.

Union Trust Co. v. Branch Mint Operating Co., (South Dakota) 134 Northwestern, 65. Jan. 17, 1912.

OIL PLACER LOCATION BY CORPORATION—AREA

Where eight persons made an association oil placer location of 160 acres and immediately afterward conveyed the same to a corporation of which several of the eight locators were officers or organizers, it was held that the prior oil discovery by the corporation would only support a claim to the twenty acres on which the well was drilled. A corporation is only one person and cannot lawfully embrace in a single location under the placer mining laws more than twenty acres, either in its own name or through individuals who are manifestly acting in its interest and for its benefit.

Coalinga Hub Oil Co., (Land Department) 40 Land Decisions, 401. Dec. 20, 1911.

ASSOCIATION OIL CLAIM—EFFECT OF CONVEYANCE OF PART

Where eight persons as associates enter upon and locate a tract of 160 acres of vacant unoccupied mineral lands of the United States under the placer-mining laws, and proceed with the work of development to make an oil discovery, but before any discovery is made they all join in conveying a specific portion of the consolidated claim to a third person who prosecutes the work of discovery on the portion so conveyed, and subsequently makes a sufficient discovery of oil, the effect of such a conveyance, in the absence of any contrary understanding, is to surrender to the grantee all of the rights which the grantors formerly enjoyed in the portion conveyed, and to constitute it a separate and independent claim; and such subsequent discovery of oil would not redound to the benefit of the portion not conveyed or suffice to validate and perfect the location of the owners thereof.

Merced Oil Co. v. Great Northern Oil Co. (California) 43 California Decisions, 303. March 22, 1912.

Concentrates

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

TRUNK-CYLINDER hoists, the so-called Anaconda type, are peculiar in their construction in that the exhaust pipe is placed above the inlet, so that cases have been known of the exhaust being connected to the boiler or air-line. Needless to say, a single-acting cylinder will not act with such an arrangement.

SCREENING tests on mill samples can only be made accurately by the wet method. The slime should be washed through a 200-mesh screen, after which the oversize can be dried and screened with comparative ease. A small amount of material under 200-mesh will be obtained in the final screening, and this should be added and weighed with the dried slime.

TITRATION of potassium cyanide by the AgNO_3 method is inaccurate in the presence of ferrocyanide, which dissolves the AgCN . It has been found by Treadwell that if the cyanide is not stronger than one-tenth normal, is rendered slightly alkaline with ammonia and 1 gm. KI added, accurate results are obtained. By this means $\text{K}_2\text{S}_2\text{O}_8$, if present, is prevented from interfering.

ZINC carbonate ore occurs at the Cerro Gordo mines at Keeler, in Inyo county, California. These mines were for many years operated as lead mines, the zinc deposits having been discovered only recently. Zinc occurs in the copper ore of the Mammoth mine at Kennett, in Shasta county, but is not now recovered from the fume, where the zinc is useful in neutralizing the SO_2 formed in copper smelting. Zinc also occurs in the Bully Hill copper ores, and experiments are now under way to develop a process for saving the zinc.

GOLD or platinum wires of small diameter, or the filaments for tungsten or tantalum lamps may be fused by the use of lead-pencil electrodes. Two ordinary pencils should be sharpened and then the wood cut away a short distance above the point, so as to expose the 'lead.' Small copper wires can then be used to connect the lead-pencils with an ordinary lighting circuit, but a suitable resistance must be interposed to prevent short-circuiting. On bringing the tips of the pencils together a small arc will be formed that is hot enough to fuse small wires.

ADVERSE claims may be filed against any kind of a mineral entry by another mineral location, whether of the same class or not; though where the classes of locations are at variance the adverse may take on the nature of a protest, as in the case of a lode claim adverse to a millsite and questioning its non-mineral character. Claimants under filings or entries other than mineral, instead of adverse mineral applications, protest against them. A co-owner who has been excluded from the application for patent by the co-owners, may adverse in his own behalf, but his adverse is more in the nature of a protest.

DIRECT air-hoists are simple in action, responding with ideal promptness to valve manipulation for either motion, but their simplicity and promptness sometimes seem to be in excess. They may hoist too quickly and may not stop the load at the precise point desired, while a careless hand may drop the load too sharply. Such a hoist also, when the air is shut off, will not hold its load continuously, slight leakage allowing a slow descent—extremely slow, if everything is all right—but still it cannot hold absolutely. The motor hoist has more than all of the desirable properties and none of these objections. It is entirely responsive to the control of its manipulator. It will hoist at any speed desired; it will stop with precision; it will hold its load absolutely for any length of time; it will lower gently and will not run down to make unnecessary slack to be taken up before the next hoist.

EDITORIAL

AN error in proof-reading in our issue of June 8 makes us speak of Joplin lead ore as selling on a 60 per cent basis. In fact lead ore there sells on the basis of containing 80 per cent of lead. It was zinc that was meant and which there sells on the 60 per cent basis, as is well known to all familiar with the district.

MINE LA MOTTE has closed again, this time as a result of the demand for higher wages on the part of the miners employed. This famous old estate in south-eastern Missouri has fallen upon evil days. All familiar with the beautiful surroundings and the long history of the property will hope that the various difficulties may be resolved and the mines and furnace again become the centre of busy and contented industry.

MEXICAN conditions are still far from satisfactory, but the area under domination of the Madero government is being steadily increased, and it is interesting to note that the smelters of the American Smelters Securities Company are working at maximum capacity. In general the large business enterprises have suffered little interference, except in the case of the railroads in the north. The insurgents in Chihuahua are short of funds and ammunition, while the federals are well supplied.

SINKING a shaft through running water without cribbing sounds like the impossible, but Mr. Leon Perret tells how they manage to do it in Russia. Putting a stove into a test pit in order to freeze the sides is also paradoxical, but it works. Many an effective native method is condemned by visiting engineers because it is crude, when in reality it is simple and excellently adapted to the work in hand. We especially commend Mr. Perret's article on 'Prospecting Frozen Ground' to engineers engaged in placer examinations.

PHOSPHATE lands in the United States seem likely to remain withdrawn from entry for some time. Mr. F. W. Mondell has introduced a bill in the House of Representatives providing that hereafter they shall "when subject to entry" be entered only under the placer laws. The Senate committee has, however, recommended favorably a bill providing that they may be disposed of "as placer or lode claims as may be appropriate." In the meantime the administration is committed to leasing, and apparently public sentiment favors the latter plan.

FINANCING China is likely to have no little effect on the silver market. Terms of the \$300,000,000 loan have already been concluded, and \$100,000,000 is to be paid over in the course of this year. Some of this will be absorbed in meeting the back payments of interest upon China's present indebtedness, but a large part will enter the country as bar silver. Whether this absorption of silver has already been fully discounted by the advance in the price of that metal since the first of the year is difficult to determine, but it seems likely that the ruling price of silver during the next few years will be higher than during recent years.

MOSQUITOES and flies are to be banished from Oroville, in a general effort to do away with conditions favorable to the spread of disease. Malaria, it is reported, has already been decreased 25 per cent. Conservation is the order of the day, and conservation of health should be first.

GEOLGISTS are in good repute in the Far North, and it is an interesting tribute to the profession that Mr. J. B. Tyrrell should have been appointed recently to head the expedition charged with the selection of lands on Hudson Bay, given by the Dominion of Canada to Ontario for railway terminals. At Dawson there is now an active protest at the detail of Mr. D. D. Cairnes to work lower on the Yukon, and the demand is made that another geologist be sent to give the expert advice needed this year in the effort to develop quartz mining near that enterprising city, which is itself named after an excellent geologist. In the bill for home rule of Alaska, now being debated at Washington, there is provision that a geologist shall serve with two engineers on the commission charged with the duty of locating and building railroads through the territory. Despite the old gibe, 'one man can see into the ground as far as another,' the ability of the scientists to see into the future seems to have impressed the practical men of the North.

NEW methods are always promising—indeed that is often their chief characteristic. We know of few, however, that promise as much for so little as one called the 'Rational Process'. Concerning it the promoters write: "The exact chemical composition of the ore must be known before the work begins. The reason of this is that all the atoms are held together by electroids, or ionic centres of force, and that these centres of force do not at all times remain constant in their potential, and therefore behave differently at different times although of the same chemical composition, and again altered when the chemical composition is varied. Then when the mass of ore is ready the whole is depolarized, paralyzing these ionoids till molecular cohesion is eliminated. By the application of a simple device the good is easily separated from the bad. In other words the gold from the slimes and the gold that the slimes carry. The time required for an assay of one pound is approximately twenty minutes. The cost thus far averages \$1.50 per ton, depending upon the transportation facilities. A plant for handling five units per day would cost about \$5000."

EXCEEDINGLY interesting things have been developed in the inquiry carried on by Mr. Samuel Untermyer as counsel for the Congressional committee investigating the 'money trust.' To the unprejudiced observer it is quite apparent that there is no discredit to be thrown upon the bankers of New York, who 'have steadily grown in power and influence; and the misuse of this power, if misuse it can be called, has been by no means flagrant or altogether selfish. In fact, the chief criticism or comment that can be made is, that the Eastern bankers have overrated their own importance; that they have come to feel a sense of ownership rather than a sense of trusteeship, and have to a somewhat unwarranted degree forgotten that the vast amount of capital piled up in New York, under their own control and guidance, belongs to the country at large, and in reality belongs to the people rather than to themselves. In all justice it should be said that the use of this power has been such as to reflect credit upon the bankers. The facts so far brought to light show rather the necessity of the provision of some check, and of a different system, than for condign punishment of those individuals toward whom the American public has recently assumed a markedly vindictive attitude. Abuse there has been, but not so much as might have been expected where such unlimited authority has been

reposed in individuals responsible to no one but themselves. A new system is imperative—as to punishment, there will be none.

KATANGA has hung like a shadow over the copper producers ever since Mr. J. R. Farrell came back from that country with accounts of Brobdingnagian deposits awaiting treatment and transportation. Millions have gone into their development, but so complicated has been the financing of the enterprise that no one has felt sure of the outcome. In the meantime the sleeping sickness has crept down from the north as railways have come slowly up from the south. At last, however, copper has begun to reach the market from Central Africa and the public is now fairly well convinced that there are large amounts of metal there to be won. American opinion has, however, settled down to the comfortable belief that the difficulties in the way are so large as to assure that the influx of new metal will be slow, and that the question of real cost is far from being settled. Now it is stated in London that Mr. Robert Williams is to surrender his control of the project, and who will be his successor is not determined. It is not unlikely that Americans will attempt to fortify their position in the copper market by taking advantage of the opportunity to join in the inevitable reorganization; if, indeed, they do not attempt to dominate it. Coincidentally it is announced in Boston that the irrepressible Mr. Thomas W. Lawson has sent an expedition to Africa to spy out the land. Only his campaign for the Senate and his desire to assist Mr. Roosevelt are said to have kept him from heading the caravan. Whatever may prove the final truth regarding Central African copper, there can be no question that the field is one admirably chosen for one of Mr. Lawson's brilliant advertising campaigns. *Scribner's* story of the journey of a 'faunal naturalist' through the lion grounds, will pale into insignificance against the lurid 'literature' we may expect from Boston next year—if the price of copper remains high.

RESIGNATION of Mr. Waldemar Lindgren, chief geologist of the United States Geological Survey, removes from the public service another of the highly skilled technical men who have given distinction to one of the great bureaus at Washington. Born in Sweden and trained at Freiberg, Mr. Lindgren found his first opening on the Northern Transcontinental Survey, that brilliant concept of Henry Villard, which did so much to give solid value to the holdings of the Northern Pacific railroad. Later Mr. Lindgren saw service in smelting, and in teaching at Stanford University, but his largest opportunity came in connection with the Geological Survey, in which he has risen from field assistant to the position of highest rank in the technical branch. He first succeeded S. F. Emmons in general direction of the investigations relating to metal mines, and later when Mr. C. W. Hayes retired to take charge of Lord Cowdray's operations in the Mexican oilfields, Mr. Lindgren became chief geologist. No one enjoys writing obituaries, and it is a pleasure to occasionally say good things of men before they die. We will be pardoned, therefore, we hope, for saying that he has filled this position, as all others, admirably and that there will be general regret at his retirement. He goes to Massachusetts Institute of Technology, where, with the new funds and new facilities available, he is certain to build up a centre of geological research of high character. The rapid successive resignations of two chief geologists, and the constant leaving of other good men occupying subordinate positions, would raise a feeling of uneasiness for the future of the Survey if it were not that the latter has deep and strong hold on the imaginations of the young graduates. Good men go but others come, and the Geological Survey is fast becoming, as an incident to its main work, a great graduate school of

instruction. To call the roll of ex-employees is almost to list the successful men of the mining profession. So long as the spirit remains right and the work is honest and thorough, the Survey can continue, like a university, to send its men out into other branches of professional service.

The Measure of Precision

The story is told of a Southern gentleman, who, desiring to employ his negro coachman as chauffeur for his newly acquired motor car, sent him to a school of instruction for some weeks. Upon his return the man showed commendable skill in adjusting the mechanism and guiding the car, and his master enquired: "Rastus, do you thoroughly understand the car?" "Yaas, boss; I unnerstan's her right froo, jest—" "Just what, Rastus." "Well, boss, I unnerstan's the whole endurin' machinery—all ceppin' whar dey keeps de mule dat makes it go." Such simplicity is ridiculous, and yet it is not too much to say that many engineers show, at times, no clearer comprehension of the real nature and limitations of the mechanisms and methods of their profession than did the unenlightened darky. Especially is this true in regard to the theory of precise measurement, and in engineering computations. A vivid illustration occurs in a paper upon precision in mine reports, recently published in the *Bulletin* of the Institution of Mining and Metallurgy and widely quoted in technical journals, in which such sentences as the following occur: "lode widths are usually measured to the nearest inch, so that it is mathematically incorrect to calculate the average width to anything less than a whole inch." * * * "The writer has not been able to find this principle definitely stated as a law in a mathematical textbook, but it would appear only a matter of common sense that, in determining the mean of a number of quantities the result should be expressed to the same degree of accuracy as that observed in measuring the several quantities." Remembering that Laplace's 'Philosophical Essay on Probabilities' was published in 1744, it is truly amazing that in 1912 such nonsensical floundering as this could find publication in the proceedings of a learned society and be quoted by supposedly well informed journals. No clearer evidence could be desired that many engineers are devoid of any understanding of the theory of probability, the difference between mathematical computation and experimental observation, and the correction and adjustment of measurements. Surely it ought to be unnecessary to point out that the quotient of $100 \div 3$ is equal to $33.3333 \dots$, but that if the value 3 has been determined by experiment or measurement to have a true value lying somewhere between 2.9 and 3.1, then the value of the quotient lies between 32.2 and 34.5, and 33 is a sufficiently precise expression of the quotient, under the circumstances. On the other hand, if we have a series of 100 determinations of the value of the divisor, the measured results varying between 2.9 and 3.1, then it will be safe for ordinary purposes to assume that the average is correct within 0.002, and say, for example, that the true value is not less than 3.013 nor greater than 3.015. The exact expression for the probable

error is: p. e. = $0.6745 \sqrt{\frac{d^2 + d_1^2 + \dots + d_n^2}{n(n-1)}}$ where n is the

number of determinations, and d, d_1, d_n , etc., the difference between each and the arithmetic mean. Obviously by increasing n or decreasing d , any desired degree of accuracy may be attained. The error in the determined figure will depend upon the methods of computation employed; thus the average error, the mean square error, or the probable error may be computed. The relation which exists between these may be obtained from Merriman's 'Method of Least Squares,' or Wright and Hayford's 'Adjustment of Ob-

servations'; two books with which every engineer who may be called upon to make precise measurements should have at least a superficial familiarity. Ostwald's 'Physico-chemical Measurements' may also be read with profit by engineers.

The difference between corrections and errors is not always appreciated. Thus, in measuring a length, the effect of changes in temperature upon the tape used causes variations in the length as determined, but the amount of the correction may be determined with as great a degree of precision as the work may warrant, while the effect of a tree branch which deflects the tape from its true catenary curve, or from a straight line, cannot be determined and allowed. According to the importance of the work, a corresponding amount of care is taken to prevent the occurrence of such experimental errors and determine the amount of all ascertainable corrections. The nature of the work, therefore, fixes the measure of precision required. In cutting a pump-room underground, it will probably suffice to fix its dimensions by pacing or by use of a yardstick. In setting the foundation bolts for the pump a steel tape will be necessary, while in boring the cylinders repeated measurement with a micrometer caliper is essential. The workman who measured the room with a caliper, or the pump cylinder with a yardstick would be regarded as a simpleton, yet in computations from experimental data engineers frequently make no less reprehensible blunders. Innumerable instances could be cited, but we forbear. The most common blunder arises from using a value experimentally determined either as divisor or dividend, and neglecting to observe what the nature of the quotient thus obtained really is. Thus if the gold content of an assay sample is determined with a probable error of \$1, and the sample is divided into 100 parts and one of these re-determined, the probable error will again be \$1. But if each of these is assayed and the arithmetical mean taken, the probable error of the mean will be a very small quantity indeed. If an erroneous determination is multiplied by a constant, its error is also multiplied, similarly where erroneous determinations are added the errors are summated. The influence of a continued series of errors is too commonly disregarded. The sample cut across the face in a gold mine may differ considerably from the true average value of the orebody at that point, but that does not constitute a valid reason for assaying the sample by crude methods, nor for carelessness in computing and plotting the results. A chain is no stronger than its weakest link, but the way to get the best service from it is to watch that link, and not by weakening all the other links in like degree. Where all the links are weak the probability that one of them will break is obviously much greater than if only one is weak.

All of which leads us to a fundamental defect in the methods of education pursued in many technical schools. It is declared that the demand of industry is for specialization, and as the time which the student is willing to devote to his education in school is limited, the fundamental principles of physics and chemistry, and their applications, are hastily passed over and the time of the student spent upon details of practice, which are expected to yield him quick returns in the shape of a well paid position. Thus the future is discounted for the quick returns of the present. There can be no doubt that an intelligent man who has had a thorough general training can, if he wishes, by entering an assay laboratory make himself in time a better assayer than the man whose general education was skipped to afford time for a long course in assaying. The same principle holds good throughout, and an engineer need not be reminded that upon the excellence of his foundation will largely depend the character of the building he plans to erect.

Success from Sticking to the Job

By E. P. MATHEWSON

*I want to avoid the pedantic style of oratory and talk to you as one who has had a little experience in your chosen profession, to those just entering the arena. It has been suggested to me by your president that I give you some account of my own personal experiences and those of friends of mine who have become prominent in the mining and metallurgical world. If you will pardon my speaking for myself, I will give you a brief account of my career.

After graduating from college, I was fortunate in securing a position as assistant topographer on the geological survey of Canada. I had several months experience in that line, returning home at the expiration of the survey. I found nothing in my chosen line of work, and so I temporarily took a position as clerk in a wholesale establishment, all the time looking out for something in the profession. Nothing turned up that winter, so I made up my mind, after consulting with some friends, to try my fortune in the Western United States.

I obtained a letter of introduction from the late T. Sterry Hunt to a man who was engaged in lead-silver and copper smelting in Colorado. This man had been a pupil of Hunt's and had gone West shortly after graduation and amassed a considerable fortune. I did not know a soul in the state of Colorado, but I met some people in Denver who gave me the following advice: "Go to the gentleman to whom you have the letter of introduction and present the letter, and if he tells you he has no position vacant, ask him if he will allow you to push a slag-pot away from the furnaces." I went to Pueblo the following day and presented my letter. It so happened that the night assayer had just resigned, so I was offered the position as night assayer of slags and refinery products at the magnificent sum of \$50 per month, the work being 13 hours night shift for two weeks and 11 hours day shift for two weeks. I liked the work and it seemed to agree with me.

At the time of entering the employ of the company, known as the Pueblo Smelting & Refining Co., there were 13 technical graduates ahead of me. Shortly after I entered the employ of the company the manager who had given me work resigned and left, and a new man was put in charge. A little later the metallurgist was offered a good position in Australia, and he left. He was followed by the assistant metallurgist, and within a short time so many changes occurred in the technical force that I found myself assistant superintendent in the plant before I had been two years in the employ of the company.

Mine was rather an exceptional case. I was assistant superintendent only one year when the superintendent resigned, and I was appointed superintendent of the lead department, there being another superintendent of the copper department. Shortly afterward the superintendent of the copper department resigned, and the manager asked me to take charge of both departments; at the same time telling me that the wages of the men in the copper department would have to be cut in half. This was a very pleasant opening, as you can imagine. I went to the foreman of the copper department, explaining my new position and the decision of the management regarding wages. The foreman told me politely that he and his men would quit, which they did.

I thereupon took some men from the lead department and put them in charge of the copper furnaces. I had never seen a charge of copper refined, but there was an article published in the *Transactions* of the American Institute of Mining Engineers by Thomas Egleston, which described fully the operation of refining copper in the Lake country. I got this article and camped at the works for 56 hours, directing the men I put in charge of the copper furnaces in every step of the process. Whenever I got stuck I would

retire to the office and consult the article, the result being that we ladled the biggest charge of copper that had ever been taken out of the furnace, and that charge was of the best quality ever taken from that furnace. After that things went smoothly enough in the copper department, as the men I had broken in took up their work readily, and as they were accustomed to furnace work, it was not difficult to train them to handle copper.

I want to say, for the benefit of you young men, that the salaries paid in those days were not what are paid nowadays for similar service. My salary, as assistant superintendent, was \$125 per month, and that large sum was only obtained after strenuous efforts on my part to have the management recognize my ability. That was the only time in my life that I ever asked for an increase in wages; but the manager, I knew, had no knowledge of the value of a technical man; and I was aware that in other establishments in the vicinity men in my position were paid considerably more than I was.

I remained with the Pueblo Smelting & Refining Co. until the year 1897. At that time the Guggenheim family had a number of smelting establishments, one of which was at Pueblo. The late Benjamin Guggenheim asked me to enter the employ of M. Guggenheim's Sons and take charge, as manager, of their Philadelphia plant at Pueblo—the idea being that as soon as I found a man to take my place I should be transferred East. The transfer was made about three months after entering their employ, and I was placed in charge of the refineries at Perth Amboy, N. J. During the next five years I was sent out to various parts of the country, including Mexico, and was for two years in South America, at Antofagasta, Chile, representing my employers.

My experience in South America was interesting. We had rented a smelting plant from a South American company that supplied us with the ore, and we divided the profits from the operation of the smelter. It was a strange thing to live on a desert, on the shore of the ocean and to receive the ore from the mines, about 30 miles away and at about three miles greater altitude. The water used for the furnace jackets and for the boilers was salt, pumped from the sea; water for culinary purposes was brought in a pipe-line across the desert, a distance of about 200 miles. This water came from an altitude of about 12,000 ft. above sea-level, and consequently the pressure on the pipe-line had to be relieved at frequent intervals by means of relief tanks, in which were openings, whereby the dust of the desert (consisting of salt, sand, and borax) got into the water, necessitating the distillation of all water used for drinking. A little distilled water is all right, but for a steady 'diet' is not to be recommended. In other parts of the coast and in the town near the smelter salt water was distilled for culinary purposes.

After two years in that port I returned to New York and shortly afterward my association with M. Guggenheim's Sons (who had in the meantime joined interests with the American Smelting & Refining Co.) was severed. A few months later I was offered a position in Montana as superintendent of blast-furnaces at the Washoe smelters, then just constructed. This position I took and a few months later, owing to the resignation of the manager, I was placed in charge of the plant and have remained there ever since.

I will now give you brief accounts of the lives of several men who are or have been prominent in the mining world. First, I recall a friend who was at one time employed by the Pueblo Smelting & Refining Co. of Colorado. The man was a graduate of Freiberg. He came to Pueblo one day without any acquaintance in the town; he applied for work at the smelter; was given a wheelbarrow and shovel and a position as laborer in the sampling mill. He did not mention the fact that he was a graduate of Freiberg, but it so happened that the furnaces were out of order and he dropped a hint to the foreman in charge as to a good way to bring the furnaces around. The foreman reported the matter to the manager and the manager asked him if he knew anything about furnaces. He said he did "know a little," so the manager gave him a trial as an assistant about

*From a commencement address, Montana School of Mines, June 6.

the furnaces. He proved that he knew his work and gradually he was advanced until he was placed in charge of the plant. Leaving that plant later on, he took charge of a smelting plant in another part of Colorado and he was then offered a position as metallurgist to the Broken Hill company in Australia. This position he accepted with many misgivings, but it proved that it was the beginning of the making of his fortune. He built up the smelting industry for the Broken Hill company and then interested himself in other companies in Australia, finally retiring with a large fortune a few years ago. He still retains an interest in the work.

Another man took a very humble position with a placer mining company in California, showed himself to be a good assayer; then later was put in charge of some small quartz properties; from there he was called to South Africa at the time the Rand was coming into prominence; showed his ability as an executive in organizing some of the big properties there and managing them, and is today one of the most highly paid consulting engineers in the world.

Another man, nearer home, worked for years as assayer in Anaconda, then in a similar position on the Pacific Coast, rising to the position of chief assayer at a large plant; then was offered a position as assistant to one of the managers in South Africa on the Rand, which he accepted. He filled that position satisfactorily and was advanced to the managership, and after several years' service in that capacity returned to America to take up the work of consulting engineer, representing the capitalists who had been his employers on the Rand.

Another man who began with pick and shovel around a smelter and gradually worked his way up to the superintendency of one of the large Colorado smelters, was transferred to Butte, where he conducted some of the earliest experiments in the use of magnesite brick for the lining of converters; from there drifted into the mining end of the business and is today one of the leading consulting mining

and metallurgical engineers of the country.

Another man began as a field assistant to the United States Geological Survey, was afterward State Geologist of Wyoming, and from there drifted to Arizona, where he became connected with the Copper Queen Mining Co. His ability soon placed him at the head of the technical force of that company, and from that he was transferred to other larger concerns and given more authority, and today is the general manager of one of the largest concerns in Mexico.

Another young man sought employment at the Washoe smelter a few years ago as a laborer, said nothing about his technical knowledge, but put in a formal application for a position when a vacancy occurred in the technical staff. He was offered a position and we were surprised to find that he had been working for us for months as a laborer. He proved his ability in the technical line and when the opportunity was offered of a transfer to another company, at an increase of salary, he accepted it, and today is the assistant superintendent of one of the largest companies in the country.

Many young men at Anaconda and Butte have worked their way up, and today there are dozens of technical men employed about the mines and smelters who are on the road to advancement.

The main things to be remembered are: not to be afraid to tackle any job that turns up; never be above your position; be sober, diligent, and faithful in business; be true to your friends and to your employers; learn to treat your associates and the men under you as men; and as soon as you can find the right girl (provided you have enough money to pay for the license) I advise you to get married. Do not wait to make your fortune before choosing your wife; if you do, the chances are 99 in 100 that you will never have one.

NITRATE export taxes for 1911 in Chile amounted to \$30,154,110.

Metal Production in Eastern States

The total value of the mine output of gold, silver, copper, lead, and zinc in the Eastern or Appalachian states for the year 1911, according to H. D. McCaskey of the U. S. Geological Survey, was \$11,787,942, against \$10,127,304 in 1910. This represents the production of 96 mines, many of them very small. The total gold output from all mines was 7709.52 fine oz., valued at \$159,370, a decrease from 1910 of \$26,152, and the silver production (recovered entirely in refining the gold and copper produced) was 108,105 fine oz., valued at \$57,296, an increase over 1910 of \$7835. Of the gold output in 1911 the placers yielded 1447.28 fine oz., or nearly 19%, the quartz ores 5699.64 fine oz. or 74%, and the copper ores 562.60 fine oz. or 7%. This 7% was derived from 801,842 short tons of copper ore mined, having an average gold and silver value of \$0.085 per ton, against 774,040 tons in 1910, having a gold and silver value of \$0.076 per ton.

The copper production from copper and iron ores was 19,605,386 lb., valued at \$2,450,674, an increase of 1,681,974 lb. in quantity and of \$174,401 in value as compared

with the figures for 1910. All the increase in output was credited to the mines of the Ducktown district in Tennessee, which contributed 96% of the output in 1911 and 94% in 1910. The copper ores yielded an average of 24.4 lb. of copper per ton of ore in 1911, against 23.2 lb. in 1910.

The production of lead, which was nearly all from lead-zinc ores, was 834,742 lb., valued at \$37,563, an increase of 635,892 lb. in quantity and of \$28,813 in value over the output in 1910.

The zinc output in 1911 was 159,351,558 lb., figured as recoverable spelter, valued at \$9,083,039, which shows an increase over the production in 1910 of 18,475,672 lb., having a value of \$1,475,741. The output of zinc and zinc-lead ores was 413,332 short tons in 1911, against 411,381 tons in 1910. New Jersey produced 97% of the zinc output of the Eastern states, the remainder being derived from the lead-zinc belt in Tennessee and Virginia and from the mine of the Northern Ore Co., near Edwards, New York.

The accompanying condensed tabular statement of the production of these metals in the Eastern states in 1911 is taken from the report.

State.	Ore mined.	Gold.	Silver.	Copper.	Lead.	Zinc.	Total value.
	Short tons.	Fine oz.	Fine oz.	Pounds.	Pounds.	Pounds.	
Alabama.....	6,360	915.06	171				\$19,007
Georgia.....	3,737	1,696.51	212				35,182
Maryland and Pennsylvania.....	219,868	.43	87	665,110			83,194
New Jersey.....	374,064					154,890,900	\$,828,781
North Carolina.....	21,810	3,399.89	943				70,782
South Carolina.....	9,302	987.24	11				20,414
Tennessee.....	604,538	562.17	106,660	18,850,276		2,234,000	2,551,774

MINE PRODUCTION OF GOLD, SILVER, COPPER, AND LEAD IN THE EASTERN STATES IN 1911.

The Castle Dome Lead District, Arizona

By J. NELSON NEVIUS

The Castle Dome mining district lies along the southwestern base of the Castle Dome mountains in Yuma county, Arizona, about 30 miles north of Dome, a station on the main line of the Southern Pacific railroad, 21 miles east of Yuma. It is 15 miles east of the old Castle Dome landing on the Colorado river, which was the shipping point for most of the high-grade lead ore produced in the early days before the railroad was constructed. The elevation is about 1300 ft. and the climate is exceedingly dry, rainfall probably rarely exceeding six inches per year. While unpleasantly hot in summer the climate is always salubrious and is exceptionally fine the greater part of the year. There is a limited supply of ironwood, mesquite, and palo verde growing in the washes, but this is not sufficient to serve as a source of fuel beyond the preliminary development of the mines. The wagon-road from Dome to the mines is unusually good. Close to Dome it crosses the Gila river where there is a mile of fairly heavy sand in the dry season, while in the rainy season there are short periods when the river is entirely impassable. For the remainder of the distance the road leads gradually upward over a gravel plain and is almost as hard and well drained as a macadamized street. The rise from the river to the mines is 1000 ft. On one trip I covered the 30 miles in an hour and ten minutes by automobile going in, and in five hours and fifteen minutes by mule team, on the return trip.

The geology of these ore deposits is rather simple. The

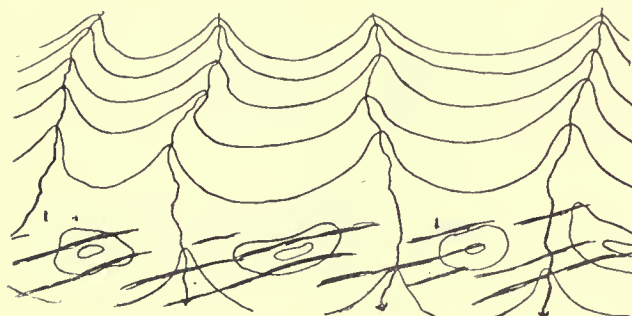

DIAGRAM OF VEIN SYSTEM.

high, rugged mountain range, of which the Castle Dome peak is the most prominent feature, is a volcanic uplift and has been the source of extensive flows of eruptive rock, mostly of a basic nature, that have occurred intermittently over long periods of time. One of the earlier eruptions was a fine-grained diorite which extended out for an unknown distance from the mountains, but has been buried by the wash forming the present surface of the plain. During later seismic disturbances along the trend of the mountain range, this diorite was tilted upward along its edge toward the mountain and became fractured. These fractures occur irregularly throughout an indefinite zone several miles long, and not as one or more continuous fissures. The veins were discovered where they outcrop on the very low foothills, and many of them have been followed out under the wash to considerable distances. Probably the persistence of the veins out under the level plain is due to the present surface of the plain covering what was the lower slope of the mountain at the time the fissures were formed. The sketch is an ideal representation of the vein system.

The outcrops of all the veins are largely stoped for a distance of three miles, beginning at the De Luce property, which is the northernmost of the chain of mines. The stopes indicate that a lens of solid galena was discovered at the surface, as practically no attempt has been made to mine or develop the concentrating ore. Near the south end of the De Luce property several shallow shafts have been sunk on the vein without finding the solid galena streak, and

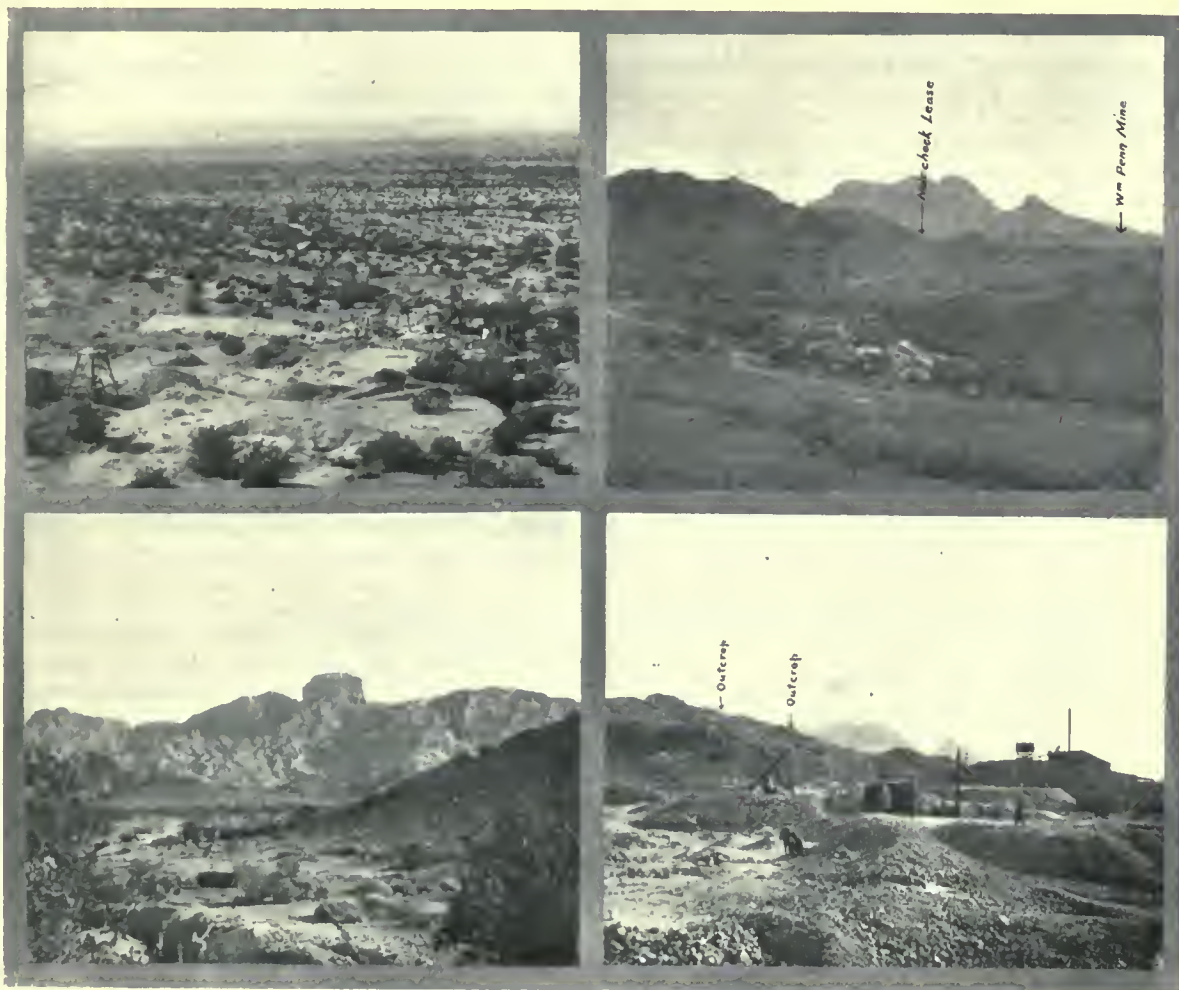

these show the vein structure. In one of these the vein at the surface is 4 ft. wide, sharply walled by diorite, and the filling is ribboned calcite carrying unoxidized inclusions of galena and assaying about 8% lead and 6 oz. silver. To the south 200 ft. another shaft shows the vein to be 2 ft. wide and containing double that amount of galena in nodules up to 4 in. diameter. Near the south end-line a shallow pit shows the vein with a sharply defined hanging wall, but poorly defined foot-wall, and the ribbon structure is less distant. The gangue is calcite with inclusions of galena and fluorite. At the De Luce mine the vein is distinctly a fissure in diorite. There are small outcrops of an acidic rock near the vein, but there is no evidence that this rock has influenced ore deposition either on this, or any of the neighboring properties. Farther to the south some of the dumps show schist, and it is said that in some cases the vein occurs between schist and diorite. This may be the basal schist of Yuma county, but it is more probably a locally metamorphosed phase of the diorite. The vein-filling varies, but the chief gangue minerals in the order of their predominance are calcite, fluorite, gypsum, barite, and witherite. In a few places galena has been oxidized to sandy carbonate, and minium and wulfenite occur occasionally. Calcite is said to occur as an important gangue mineral only within 150 ft. of the surface, below which it gives place to fluorite. The latter mineral occurs almost universally with the galena, and the typical ore-section is a core of solid galena ranging from 3 in. up to 2 ft. in thickness, enclosed within a foot or two of mixed fluorite and galena. Very frequently the galena streaks occur along the hanging wall, underlain by fluorite. Clearly these two minerals are intimately associated in the vein in varying proportions, and form an ore which can be cheaply mined, crushed, and separated. The general strike of the veins is northwest and southeast and they dip steeply northeast, toward the mountains.

The De Luce mine is the northernmost of the group, and has been known at various times as the 'Fera mine,' the 'Castle Dome mine,' and the 'La Lola mine.' From the south end-line the vein can be traced by outcrop and through the mines for 1400 ft., to where it disappears under the wash, just north of Shaft No. 1. How far the vein will continue north of this point can be determined only by development. The shaft is an incline on the vein 220 ft. deep, and the vein exposed in the workings to the north is from 3 to 4 ft. wide, and samples that I took assayed from 5 to 20% lead and from 7.3 to 3.3 oz. silver. As the ore is fluorite with included galena masses of small size, very little dependence should be placed on moil samples. The former operators contented themselves with mining only the solid galena, and did no development beyond the limits of the high-grade ore. This is true of all the mines. The orebody occurring in this mine is irregular, 450 ft. long, and was stoped to a depth of about 300 or 350 ft. It is said that the bottom levels—350 and 400 ft.—show from 2 to 4 ft. of ore ranging from 30 to 60% lead. This could not be verified, as the water stands at the 300-ft. level. The old irregular stope is open to water, and the walls are firm. A few pillars of low-grade ore show the usual mixture of fluorite and galena, also in many places some of this is left on the walls, but probably it would not pay to reopen the stopes and mine it.

A peculiar feature of this mine is that at Shaft No. 2 the stope leaves the vein which it has followed south of that point and follows a distinctly different vein some ten feet in the foot-wall. This condition was noted on two levels, but it remains to be proved by development whether the two veins will continue to carry ore, or whether this condition is due to a 'linked' structure in the fissure—in which case the unexplored portions may be expected to feather out quickly. The exposures of both veins are so strong that

there seems to be a probability that two distinct ore-bearing veins approach each other within ten feet and then diverge. The stopes are from 2 to 5 ft. wide and are practically continuous from the surface to below water-level, consequently it is readily appreciated that the mine must have yielded a large tonnage of ore in proportion to the vein-area exposed. The deepest working is Shaft No. 4, which is said to be 470 ft., of which the last 70 ft. is said to be in profitable ore which has not been mined. The surface equipment is negligible, the shafts are very small and no attempt has been made, either at this or any of the other properties, to develop along economic lines. The type of the vein fissures, the nature and composition of the gangue, and the lateral extent of the veins, indicate that they may be expected to

that level. This water is potable and the supply is said to be about 10,000 gal. per day. There are no springs of consequence in the neighborhood, but the arroyos offer possibilities, and in case the region develops important mines, water can be pumped from the region of the Colorado river. Freight on ore to the railroad should not exceed \$3, as it can be contracted at \$3.50. There is sufficient fuel at \$4 per cord for preliminary work, but not sufficient for extensive operations. The vein walls are firm and the ore is soft and is ideal for concentration. At present the fluorite cannot be regarded as an asset, but it may become salable in the future, as a remarkably pure grade could be supplied. Seven shipments of ore from the De Luce mine, totaling 100 tons, averaged 70% lead and 30 oz. silver, the two extremes

WASH COVERING OUTCROP, DE LUCE MINE.
CASTLE DOME PEAK FROM THE MINE.

LOOKING SOUTH ALONG VEIN SYSTEM.
DUMPS AT DE LUCE MINE.

continue to a considerable depth below the present workings.

The Arkansas mine adjoins the De Luce group on the south, and is on the continuation of the same vein. The entire outcrop has been stoped across the shoulder of a low hill, a distance of some 300 ft. The depth is said to be about 300 ft., but the old works are inaccessible. The walls are diorite and the dump consists chiefly of fluorite, all the galena having been sorted out. Southeast from the Arkansas mine are scattered many other old properties now idle. Apparently these are all in the condition of the De Luce property, namely, that the high-grade galena has been stoped to a depth of 200 to 300 ft., and no attempt has been made to develop or concentrate the lower-grade ore. Among the properties in this district that have been partly developed are the New Deal, Flora Temple, Lady Edith, Chilson, Sonora, William Penn, Silver Dollar, and Nole-check.

The general conditions affecting the development of these mines are fairly good. The most serious problem is the absence of water, but as the De Luce mine found water at 300 ft. it is probable that other mines will also reach it at

being 65.8% lead with 28.9 oz. silver and 72.2% lead with 28.6 oz. silver. Shipments from other mines are said to have maintained this standard.

CHROMITE production in the United States in 1911 amounted to 120 long tons, valued at \$1629, according to W. C. Phalen in an advance chapter from 'Mineral Resources of the United States for 1911,' just published by the U. S. Geological Survey. This figure of production represents the amount that was actually sold or entered the market. The quantity mined was considerably greater, but some of the ore mined did not enter the market owing in part to a somewhat curtailed demand and in part to the difficulty of transporting it. The ore sold came from Shasta, Siskiyou, and Tehama counties, California. Some ore was reported as having been mined in Converse county, Wyoming. California ore is used principally in the manufacture of furnace linings.

COAL has been discovered north of Santiago, Chile, in the province of Aconcagua.

Prospecting Frozen Ground

By LEON PERRET

*The process of working platinum alluvial deposits is in the main similar to that adopted in gold mining, although a great difference does actually exist in certain technical details. The methods of prospecting to be described apply equally to gold and platinum deposits. They have not been confined to the practice prevailing in the Ural mountains, but also deal with methods in use in other parts of Siberia.

Everywhere along the Urals and in Siberia it is the accepted rule to place the prospecting pits or bore-holes in straight lines across the alluvial deposit. The system of distributing the prospecting pits or bore-holes at the corners or centres of squares, as is the practice, for instance, in California, when prospecting alluvial deposits for dredging, is not in use in Russia. To determine accurately the direction of the line of pits depends to a great extent upon the experience and powers of observation of the prospector, and even becomes a sort of special gift, similar to the power of diagnosis in a doctor. I know of many instances where the metal-bearing portion of the deposit was not found owing to the line of prospecting pits being wrongly placed, and when the direction was altered it disclosed a rich pay-streak.

In places where there is little snow during the winter, and where the temperature for three or four months keeps at 25 to 50° C. below zero (−13 to −58° F.), as, for instance, in the Amur province or on the eastern side of Lake Baikal, the frost is successfully used for sinking pits, by a method called 'frost prospecting.' This method is the following: At the beginning of the winter, before the frost has set in, pits are sunk to water-level; with the advent of heavy frosts, the pits freeze hard. When the sides and the bottom of the pit are frozen to a thickness of 2 or 3 ft.—and in the localities named, this would take place after a week or ten days of heavy frosts in the first half of November—small piles of wood are placed in the bottom of the pits; they are called 'burners' and after having been set alight, they thaw the frozen ground for approximately half an arshine (14 in.) all round. As soon as thawed it is dug out of the pit. The pit is allowed to freeze for a few days and the operation is repeated, so that by alternately freezing and thawing the pit is sunk to bedrock. The whole art in this method consists in being able to determine correctly the amount of wood required for the 'burner,' and the amount of heat derived from it, bearing in mind that the draught increases with the depth of the pit. Too large a 'burner' would completely thaw the frozen wall which keeps the water from the pit, and this would speedily be inundated ('ripped,' as they say). On the other hand, an excessively small 'burner' would thaw too little ground, and the sinking would be delayed. There are no rules for determining the size of the 'burner', and it depends solely upon the experience of the workman. Skilled and experienced workmen achieve great success by their ability in determining the quantity of wood required by the nature of the ground. Gravel possesses a greater power of conducting heat than clay soil, and therefore requires less fuel than the latter. Slimy ground, or ground that produces a slimy mud which prevents the heat from penetrating, is rather more difficult to thaw. Care must be taken that after each thawing a protecting layer of frozen ground should remain about 1 ft. thick. This the experienced Siberian workmen can tell by the sound when tapping the bottom and sides of the pit with the butt-end of a pick. When the frozen ground is thick, tapping produces a dull sound, while when it is thin the sound will be resonant (the pit 'rings,' as they say).

When a pit become drowned in consequence of being over-fired it is difficult to freeze out again. If this happens they allow the accumulated water to freeze and then take off a thin top-slice of the ice, but not all of it, and allow the pit to freeze over again for a few days while the layer

of ice gets thicker. By thus taking the ice off in slices they manage to get down to the bottom of the pit. This operation is a slow one, and occasionally to expedite matters conical sheet-iron pipes of 7-in. diam. at the closed bottom end, and 10-in. diam. at the top end, are placed in the pits in rows; they are loaded to prevent floating, and, as they allow the cold air to get to the bottom of the pit, they hasten the freezing process.

Before putting the pipes into position enough earth is thrown into the water of the inundated pit to dirty it, because dirty water freezes quicker than clean water. When the area covered by the pipes has frozen hard, a little warm water is poured into them, a thin layer of ice surrounding the pipes is thawed, and the latter can be pulled out without difficulty. This explains the conical shape of the pipes. No timbering of any kind is necessary, since the frozen sides of the pit stand well. The raising of the excavated material to the top is done either by a shovel or with a bucket and windlass. The first system is the cheapest, and the Siberian workman, especially in the Amur provinces, has attained an astonishing amount of skill in throwing the material to the surface, and in keeping separate piles of the material mined from each quarter-arshine (7 in.) of depth. The piles are distributed along the periphery of a circle at a distance of, approximately, two arshines (56 in.) from the pit. On approaching one of these pits it is an extraordinary sight to see the dirt being thrown up at regular intervals and to find that each shovelful, with almost mathematical precision, falls on one of the many surrounding heaps. These are afterward washed to determine the metal content.

The dimensions of the pits are generally 9 by 11 or 10 by 10 quarter-arshines (5 ft. 3 in. by 6 ft. 5 in. or 5 ft. 10 in. by 5 ft. 10 in.). A Siberian prospector, standing in the bottom of a pit of these dimensions, can throw the excavated material from a depth of 25 quarter-arshines (14½ ft.), and there are crack men who can throw it from a depth of 20 or even 24 feet.

The depth to which this kind of working may be carried depends not only on the strength and skill of the workman, but also on the nature of the ground. Gravel being lighter, and separating more easily from the shovel, can be thrown out from a greater depth than heavy clay soil. Generally speaking, one can say that when throwing the excavated material with a shovel a pit may be sunk, on an average, in gravel to 25 quarter-arshines (14½ ft.), and in clay to 20 quarter-arshines (11 ft. 8 in.). If the depth of the pit is greater, 'shelves' are resorted to, that is, recesses are made in the walls of the pits, in which rest small beams. A floor of boards or poles, covering about half the pit's section, is made on these beams. The material excavated is then thrown out in two stages.

The pit is entered and left by means of a rope. It is essential that this be well protected, as when lighted the strong draught causes the 'burner' to flare up in an instant. At a depth of more than 25 or 28 ft. a windlass is required, but in 'frost prospecting' they endeavor to do without it as much as possible. The sinking of the pits, being intermittent, would necessitate a windlass at each pit: in addition they require one or two men to work them.

The workmen are divided off into pairs, a workman having the right to choose his mate. A pair of these workmen are given 30 pits, which they usually sink in the course of the four winter months, from November to March, or until the heavy frosts cease. On an average 3 ft. of sinking is done per single day shift. Besides the sinking of the pit it is also part of the men's duties to cut, transport, and break up the wood for the 'burners.' The number of pits above mentioned enable the workmen to easily attend to all of them in turn without their being tempted to fire them too frequently. The 'burners' are lit always at nightfall, and, where large prospecting operations are in progress, the several lines of pits present a fascinating sight.

Taking the average earnings of the Siberian workmen during the winter months as Rs. 50 (\$25.75) per month, and the average depth of the pits as 30 quarter-arshines (17½ ft.)—this being about the average depth of the alluvial de-

*Abstract from an article on 'Gold and Platinum Alluvial Deposits in Russia,' read before the Inst. Min. & Met., London, May 16.

posits of the Amur and Trans-Baikal provinces—we find that 900 quarter-arshines are sunk for a cost of Rs. 400, or, in other words, that the cost of sinking per foot amounts to \$0.39. To this must be added the salaries paid to overseers, the cost of washing the samples, and the upkeep of a few horses which are given to the workmen in turn for carting wood, but even then the cost of sinking does not amount to more than \$0.46 per foot. The consumption of wood varies from one-third to half a subic sagene (0.9 to 1.3 cords) per pit of from 18 to 20 ft. in depth.

It is doubtful whether there exists a cheaper or more convenient method of working than that described, and, bearing in mind the sparsely colonized settlements, it has the important advantage of being entirely free from breakdowns of any kind, which are the unavoidable adjunct of all methods entailing the use of machinery. The absence of a heavy equipment renders this method specially suitable for prospecting work in distant localities for prospecting parties and expeditions. The possibility of 'frost prospecting' requires three essential conditions: (a) not much snow; (b) heavy uninterrupted frosts during a few months; (c) that the alluvial deposit should not be too deep.

The total depth of the alluvial should not exceed 30 ft., since at greater depth the ground either freezes slowly or else does not freeze at all. If the depth is more than 25 to 30 ft., 'frost prospecting' is resorted to for that depth, but additional sinking is done in the ordinary way.

In localities with heavy snowfall, the pits are constantly being filled and covered over by it. This causes excessive work through the necessity of cleaning them; while, in addition, the frost cannot take effect under the snow, and consequently the sinking proceeds so slowly that the pits do not reach bedrock before the heavy frosts are over. This is the reason why 'frost prospecting' is not practised in the Urals, the coast provinces, or the Yeniseisk Government, although the cold is intense. In the centre of the Urals, at the platinum mines along the River Iss, I made experiments with the view to introducing this method, but the results were unsatisfactory.

The second condition also essential, heavy frosts over long periods, may be assisted by artificial means, particularly when sinking deep pits or when the cold does not quite attain the required intensity. The artificial means may be one of the following three:

1. In this method the pit is divided into two halves by a cloth brattice across its width and extending from the top to within 3 ft. from the bottom. An ordinary-sized iron stove is placed at the bottom of the pit, and rests on iron rods let into the sides of the pit. It is lit and fired from one half of the pit, while the chimney leads into the other half. This needs firing twice a day only; a strong draught is produced, and a frost of not more than -20 to -22°C . (-4 to -7.6°F .) is sufficient to freeze the pit for about 1½ ft. in depth, and much more round the sides.

2. Here the pit is divided by a brattice in the same way, with, however, this difference, that the two divisions are not of equal size, one being twice as large as the other. The brattice extends to within 3 ft. of the bottom. The larger division is covered at the top by a closely-fitting floor, into which is inserted a rectangular wooden pipe made of tight-joined boards with inside dimensions 21 by 28 in. At a distance of 4½ ft. above the floor an iron grating is fixed; this is accessible through an opening provided with a tight-fitting door. Through this opening a perforated drum of sheet iron is placed on the grating—it contains enough charcoal to keep burning for about two hours. This is repeated about three times every 24 hours. The pit is frozen more successfully and more quickly in this way than by method No. 1, but method No. 2 is more intricate to adopt.

3. An iron stove is placed at the mouth of the pit, with two pipes of 3 to 4 in. diam., one the smoke-stack, and the other the air-supply pipe. This latter extends downward and is let into a bottomless iron box at the bottom of the pit. The iron box is smaller than the pit, so as to leave a space all round it of from 10 to 14 in. The lower part of this box is connected with another draught pipe opposite the one first mentioned—this leads to the top

of the pit. The two pipes on the shaft are made of sheet iron, with telescoping joints. The height of the iron box is from 24 to 28 in. The open side of the box, which is toward the bottom of the pit, must be made air-tight by sinking the box as much as possible and piling up earth round it. The doors of the stove should shut tightly, which is best attained with asbestos packing. If the stove is kept continually alight, the bottom of the pit can be frozen by this method in half the time for either of the first two methods. The sides of the pit freeze independently.

The cost of sinking by using any one of the above three methods is about the same as with freezing without forced draught. In the Yeniseisk district experiments were made with air-blowers to hasten the freezing, but they required mechanical energy, which meant expense; they were cumbersome and made transport difficult, so that they were abandoned.

'Frost prospecting' also admits of prospecting the beds of running rivers. To carry it into effect the ice covering the river, which should be about 20 in. thick at the place where the pit is to be situated, is cut away about 12 in. over a section of 7 by 9 ft. The cold penetrates the remaining ice, and in a few days the ice at the bottom of the place which has been laid bare has again attained its former thickness. The operation of sinking or stripping off another 12 or 14 in. is then repeated, and the place is again left to freeze for five or seven days, according to the frosts. By continuing this the bottom of the river is eventually reached through a cylindrical pit sunk through solid ice, which sometimes is so transparent that one can see through the walls of the pit. I once sunk such a pit in a river 5 to 7 ft. deep, in which the speed of flow attained 6 versts (4 miles) per hour.

The chief condition for this work is that the picks should be very sharp, so as to strip the ice off in thin layers. The work also requires great precaution and experience; the thickness of the ice remaining at the bottom of the stripped hole is ascertained by striking it with the butt end of a pick-axe, and experienced workmen rarely make a mistake. If by accident the ice is broken through, and water rushes through the opening, the best means to stop the inrush is to replace the pick into the hole; the cold from the steel causes the hole to again freeze over quickly and the pick can be got out as the sinking proceeds. Wooden wedges, sometimes used for this, strain and crack the ice.

The greatest caution is necessary when the bottom of the pit is reached, as it is here that cracks form more easily than anywhere else in the pit. I believe this to be due to a certain amount of shrinkage of the ground from the ice when it is exposed to the frost. The sinking of more than one or two pits diametrically across the river should be avoided, since this impedes the current and the water is liable to raise the ice in various places, causing cracks through which the pits are flooded. The best remedy for such an accident is to instantly stamp down large lumps of ice into the pits, which will quickly set into thick masses of ice and can then be dug out again without difficulty. The conical pipes above referred to may also be used successfully in such a case. When the pit has reached the bed of the river, it is left for about ten days to freeze, after which the first burner, a small one, is lit, and it is considered highly satisfactory if 6 or 7 in. of the ground has been thawed. Further sinking of the pit is carried on as above described, and its dimensions are decreased to the ordinary size. The part of the pit sunk through the ice is made larger—7 by 9 ft.—in order to prevent the sides of the ice-pit melting from the heat of the burners.

A few districts (such as the greater part of the Lensky and Irkutsk provinces, as also part of the Amur province) have ground which is perpetually frozen. Here the pits are sunk by means of burners in the same way as above described, with this difference, however, that the firing goes on continuously, and, while the burner is alight in two or three pits, the excavated material is being thrown out of the remaining two or three; in this way, up to six pits per day can each be thawed and excavated.

The Iron Ranges of Michigan

By P. B. McDONALD

The Marquette, Menominee, and Gogebie ranges of northern Michigan, by the close of the season of 1912, will have produced approximately 250,000,000 tons of iron ore. Calling \$4 the average selling price per ton at the lower lake ports, the total value approximates \$1,000,000,000. It is probable that at least as much more will be produced in the future as has been mined in the past, making a grand total of \$2,000,000,000. The estimating of ore reserves on the intricately folded Michigan ranges is not conducted

that Mr. Finlay says of the Iron River district: "All these comparisons would lead one to believe that this district would produce 110,000,000 tons by the time it reaches the state of development in which the other districts are now." Yet his figure for total tonnage expected from the district is only 42,122,000. One mine at Iron Mountain, the Chapin of the U. S. Steel Corporation, has produced 18,000,000 tons of ore and is estimated to contain 9,000,000 tons more; this total of 27,000,000 tons at the lower lake ports would be worth \$108,000,000 at \$4 per ton. The old Lake Superior mine at Ishpeming, opened in 1857, has shipped ore every year since, making a total of 15,000,000 tons, and is estimated to be good for twenty years more. The Newport mine of Ferdinand Schlesinger at Ironwood, assessed at \$8,535,000 for ore in the ground, had a tax levied against it in 1911 of \$100,000.

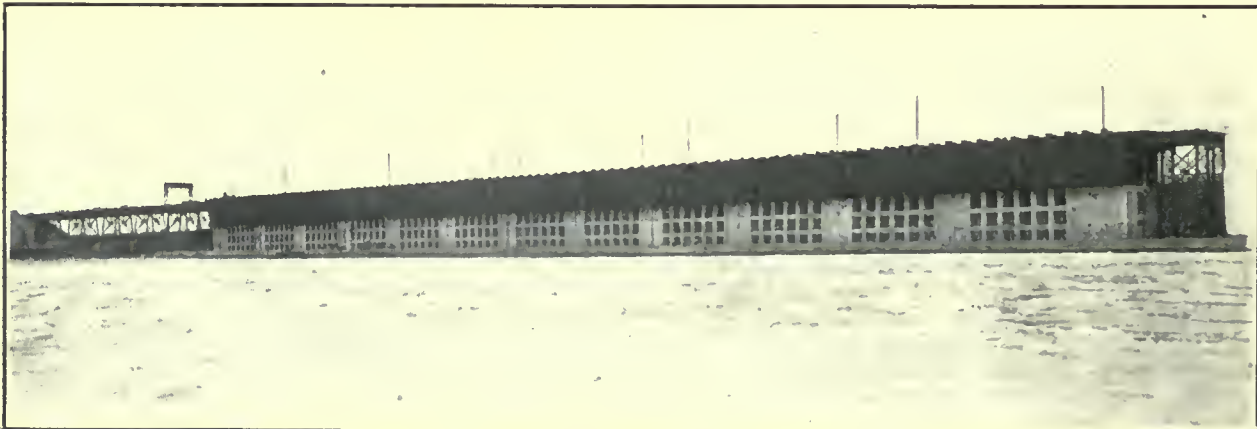

During the season of 1910 there were 77 mines on the Michigan iron ranges which made shipments of ore; at the present time several of these are closed because of dull times in the iron market. There are, however, a number of new mines developing which will ship ore for the first time within the next two years; this is particularly true in the Iron River district, where a dozen diamond-drilled properties are being developed by shafts for producing ore. The prevailing business conditions of the country have each year a marked effect upon the Lake Superior iron mines. It is predicted that the lowering of the import duty on iron ore will permit most of the

with the ease possible in predicting the future of the great Mesaba range in Minnesota where the shallow flat deposits lying just under the surface are quite accurately delimited by churn-drill holes, nor is there any great necessity for trying to develop ore too far ahead of actual mining. It is predicted that the deeper iron deposits of Michigan will

blast-furnaces on the Atlantic seaboard to obtain their ore from Cuba, Newfoundland, Sweden, or Brazil, while the Rocky Mountain and Pacific Coast states will probably get ore from deposits in their own territory or from Oriental countries, such as China. This leaves to the Lake Superior district the furnishing of iron ore to the great industrial

DIAMOND-DRILLING AT NEGAUNEE. THE LANDS WERE CONSIDERED VALUELESS FOR YEARS UNTIL DEEP DRILLING DISCLOSED LARGE OREBODIES.

THE NEW STEEL AND CONCRETE ORE-DOCK UNDER CONSTRUCTION AT MARQUETTE FOR THE CLEVELAND-CLIFFS IRON CO.

be producing ore when the Mesaba is a barren waste, even though the latter now overshadows the older districts in amount of ore blocked out.

J. R. Finlay, in his recent appraisal of mines for the State Tax Commission, put a value of \$119,150,000 on Michigan's iron ore reserves, his estimate of the present worth of ore in the ground being 50c. per ton; no value being put upon unexplored iron-ore formation, of which there is a large amount. As an example of the conservatism of this estimate of future production, it may be noted

territory extending from the Appalachians to the Rockies.

Michigan is particularly fortunate in the large amount of unexplored territory likely to contain iron formation: recent developments in the Iron River and Crystal Falls districts by independent companies have indicated the possibilities in this direction, as have the discoveries by the Cleveland-Cliffs Iron Co. on the Swanzy range south of Negaunee and at North Lake west of Ishpeming. There is a great amount of territory underlain by iron formation, lying between the Marquette range and the Menominee

range, and the U. S. Steel Corporation and the Jones & Laughlin Co. have been conducting dip needle exploration and diamond-drill work there during the past winter. Other promising regions are as follows: between Iron River and Crystal Falls; between Florence, Wisconsin, and Iron Mountain, Michigan; between Amasa and Crystal Falls; and in the Atkinson country northwest of Iron River.

There have been many decided innovations in the practice on the Michigan ranges during the past ten years. The old method of exploration by shafts and test-pits has largely given place to diamond-drilling by which orebodies are searched for to a depth of 3000 ft. The tendency has been toward fewer and more permanent shafts, with concrete gaining in popularity as a lining. Electric haulage underground is common, and several water-powers have been de-

Mine Accidents and Their Prevention

By ED RYAN

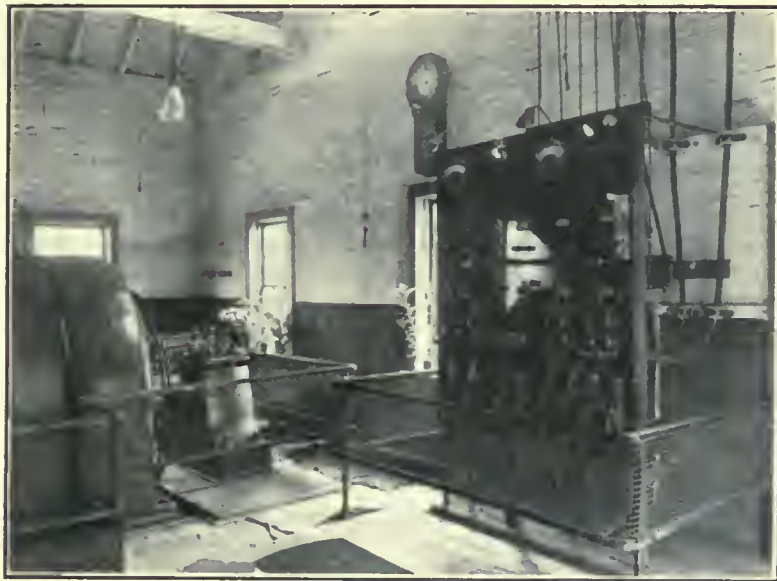

*In the hunt for and production of gold, silver, and other metals, men are called upon to follow a vocation which is extremely hazardous. To lessen the number of accidents and fatalities is certainly worthy of the time, attention, and thought of our best men. The old world is farther advanced than are we in the matter of providing protection for the toilers and in taking care of those left dependent by reason of fatal accidents. It is realized

there that the greatest and best resources of any nation are its producers; those who work, and that when you add to their health and comfort and by the passage and enforcement of wise and wholesome laws, protect them, you add to their self-respect, increase their earning power, and thus add to and conserve one of the greatest of the nation's resources. From a humane standpoint all agree that the prevention of accidents is absolutely necessary. From a business standpoint it is equally wise. Dr. Kaufman, president of the German Insurance Department, says: "The wisdom of giving employers' associations all possible freedom of action becomes especially evident in accident prevention. Recognizing that it is of prime importance to prevent injury, since compensation will never replace a father who has been killed or make up for lost limbs, state officials and officers of employers' associations have concentrated their efforts upon prevention, and with wonderful results. Scientific accident prevention is now recognized as a special and important branch of technical engineering.

Invention and prevention have gone hand in hand in this work as advance agents of civilization. The workers' lives preserved means maintenance and increase of our national resources and gives plentiful returns for the heavy financial burdens which social insurance places upon our economic structure." Dr. Spiecker, chairman of the League of German Employers' Associations, says "Twenty-five years have changed obligatory results to voluntary performance. Today everybody who views the situation without prejudice must acknowledge, and does acknowledge, that the task of employers' associations in this field, prevention and compensation, is a great blessing, not only to the workers, but to the industries and the nation. It is perfectly evident today that higher efficiency in industries has been secured by increased workers' efficiency, all brought about by relieving our workers from worries and distress on account of sickness, injury, superannuation, and invalidism. The spirit which enters into this problem is best illustrated by the fact that in addition to the systematic work carried on by the state, employers' associations, and individual employers, a large fund was raised a few years ago by voluntary subscription among employers and the general public, for the special purpose of stimulating and promoting accident prevention through investigation, education, and invention. The occasion for the establishing of this fund was the silver wedding of the German Emperor. He, with the best men of the nation, believes that a monument of this sort is of greater lasting value than marble or bronze."

It might not be amiss to quote from a recent speech made by Mr. Roosevelt along the same line. He said: "Let us remember also that conservation does not stop with the natural resources, but that the principle of making the best of all we have requires with equal or greater insist-

*Address before the Engineers' Club, Mackay School of Mines, by the Mine Inspector of Nevada.

SAFETY DEVICES AROUND MACHINERY AT MINES OF OLIVER IRON MINING COMPANY.

veloped to furnish power for hoisting and compressing air. At Vulean on the Menominee river the Penn Iron Mining Co., a subsidiary of the Cambria Steel Co., is successfully operating the Sturgeon Falls plant; at Marquette the Cleveland-Cliffs Iron Co. has completed its Carp river plant for furnishing power to its mines in the Marquette and Gwinn districts; near Iron Mountain the Peninsula Power Co. is developing the Twin Falls water-power for retailing power to independent companies in Iron River and Crystal Falls. Electricity has been successfully applied to hoisting machinery, either directly or through a motor generator set which, though costly, eliminates peak loads at the powerhouse. Air-compressors are run directly by electric power. Changes in underground practice have tended toward lighter, quicker rock-drills, run by one man, or two machines in a heading run by three men; the application of water to the drill-hole for removing chippings has been the subject of much experiment and has been solved in a variety of ways, depending upon the ground. Carbide lamps are gaining favor in place of candles or 'miners' sun-shine.' In surface construction, steel head-frames are common, as are steel and brick buildings; concrete is used a great deal, and the so-called 'hy-rib' concrete construction for building has proved satisfactory in service and is cheaper than brick.

MANGANESE ore deposits occur at Cay bay in the Dutch part of the island of St. Martin, West Indies, not far from the town of Philipsburg and quite near the sea. Some ten or twelve years ago two shipments of manganese were made to New York and sold readily, the analysis showing about 44 or 45% manganese. Not long ago the deposit was visited by a Dutch government engineer, whose opinion was favorable. Though there are outcrops of manganese in various parts of the island, Cay bay is the only place from which ore suitable for shipping has been obtained.

ence that we shall stop the waste of human life in industry, and prevent the waste of human welfare which flows from the unfair use of concentrated power and wealth in the hands of men whose eagerness for profit binds them to the cost of what they do. We have no higher duty than to promote the efficiency of the individual. There is no surer road to the efficiency of the nation." Men who have given the question thought agree that protection to the soldiers of industry adds to the strength of the nation. But how to get that protection is the question.

Superintendents and managers know from experience that the expense of providing better working facilities is more than returned by the confidence the workman has in his employer, and this awakening and strengthening of his energy which comes from the knowledge that his employer has his interest at heart and is doing everything possible for his protection. It has been well said "His is the mental attitude of the soldier who knows he is fighting under a capable leader and who stands ready to go through fire and water if necessary." These superintendents and managers are frequently denied this possible advantage by the folly of a niggardly board of directors, far removed from actual operations, and whose knowledge of mining is so limited they cannot look beyond the original cost of some device. I often think what a blessing it would be if many of the managers could follow the example set by Admiral Dewey, and cut off all communication, leading to the board of strategy and use their own judgment.

In times past it was perhaps true that liability laws passed by the states have been a fruitful source of dissatisfaction and friction between employer and employee. But in late years, especially since a majority of the courts have defined more clearly the contributory negligence clause, employers, especially the more humane ones, have taken more interest in providing systems of relief and prevention, many of which are models and have attracted the attention of thinkers in that line. The mandates of common humanity should cause all to get together on this important subject. In Nevada, since the passage of the present employer's liability law, the mine managers have met and exchanged ideas on the subject of accident prevention. Such meetings are bound to bring good results. Why not go farther in these meetings and take in the miners? Let them know they, too, have a duty in this connection. A man working daily in an atmosphere of danger becomes careless of his surroundings and thoughtlessly takes chances uncalled for and which he would not take were they called to his attention. Almost daily men not only expose their own lives but those of others. Many of them do not understand that they are asked to do or not to do a certain thing because of the law. Bosses cannot constantly watch over them, therefore they must share in the responsibility of carrying out the law. Let all meet together, discuss frankly our responsibilities, tell one another what is expected, and a better feeling will prevail. Only a short time ago, while standing at the collar of a shaft of one of the mines in the southern part of the state, I saw a cage loaded with men come up, the 'eager' was on the cage, and the gates on the cage, which under the law must be closed when hoisting men, were open. I do not believe he understood the urgent need of the gates. How much better equipped he would be to fill such a position of responsibility if he could but attend a meeting and hear discussed the duties of a eager and the terrible consequences which are almost sure to follow any carelessness on his part. Let him know that he is one of the spokes in the wheel of industry, that the law wants to protect him, and in turn wants him to help protect others. Occasionally men may be seen riding on cages with tools, contrary to orders; in fact there are many infractions of the law which could and would be done away with were they discussed in the meetings of the different labor organizations in these joint meetings as before suggested.

Unfortunately for the industry, many men work in the mines in positions where not only their own but the lives of others may be sacrificed through a failure to comprehend an order, but who can neither speak nor understand

the English language. Such a condition is deplorable, and steps should be taken by the law-making power to curtail, as far as possible, this growing evil. The other day I went through a property where most of those employed underground were unable to speak or understand our language, and there was a sharp contrast with the conditions in mines in Virginia City where English-speaking miners are employed. Here the boss and men discuss conditions, and any orders given are readily understood. In the other, well, it was impossible to make them understand either by words or signs, and the boss, in an effort to enlighten them, goes through signs and gesticulations that would make a mute think himself a professional linguist. The bosses have given strict orders for the men to pick down the places in which they work, to timber when necessary and plenty of timbers are provided, and not to place burning candles around on the timbers. And yet I found flagrant violations of those orders, and when the boss would take the pick and sound the back and, finding it dangerous, by signs and motions make them pick down, or make them put out a burning candle that had been placed on a timber, they would look at him in amazement. Evidently they did not understand the orders given. Now it seems to me when a person unable to understand the language spoken by those in charge, gets hurt or killed, even though he has violated an order given, the company should be held responsible, for the one issuing the order, knowing it was not understood, must be presumed to have done it merely as a matter of form.

Fortunate indeed is the young graduate, who has the health and strength when leaving school, who secures a place in the mines under some progressive mine manager. Take a position as shoveler, learn to run a machine, to timber, contract a little so as to be thrown on your own resources, study the different methods used, get right in and be one of the boys, learn their customs, see what they have to contend with, and you will find that you have picked up many things not to be found in books, and you will be the better for it. Add to your technical knowledge practical experience, knowledge of the habits and desires of the miners, which is only gained by associating and working with them, and your services will be sought. Many have the technical knowledge, but by reason of lack of knowledge of human nature they fail when called upon to handle men.

The history of mine inspection in the state of Nevada is brief, as the law creating the office of Inspector of Mines was only passed in the year 1909. The law was a compromise, as a bitter fight had been waged against the original bill, the claim being made that it would cause the closing of many mines. The present inspector was appointed deputy at that time, and well do I remember the frowns with which I was greeted on my first visit to many mines, and it seemed that the less the experience of the man in charge the darker the frown. Many seemed to regard the mine inspector as a natural enemy. It was a new and untried field as far as Nevada was concerned, and I realized that to properly place the functions of the office before the people one would have to move with great care. It took some time to get acquainted, but after getting acquainted, all learned that each was imbued with the same spirit; that of building up the great mining industry of our state.

With large areas of mine development comes increased risk to the men employed therein, and with such increased risk comes the necessity of better safeguarding them. So with that end in view I, believing the law as it existed failed to meet the required needs for better protection, reported to the Governor and Legislature, and made certain recommendations, which were later drawn up as a bill, introduced, and passed unanimously. This law provides that only powder enough for 24 hours' use shall be stored underground, and then only in such a place that its accidental explosion will not cut off the escape of the miners working in the mine. One not acquainted with the facts would perhaps say that provision is needless, as one would not store sufficient powder underground to do any damage. Prior to the passage of this law I have found as high as three tons stored underground, and that but a short distance from the shaft. Even then some tried to argue that there was no

danger. Some of the most terrible disasters known to the mining world were caused by just such storage. The use of wooden tamping bars is enforced by an old rule in vogue in nearly all the mining states, yet we found in some of the mines metal bars being used. The need of a law forbidding the use of gasoline was forcibly brought to my attention by the killing of two men in Manhattan. A small engine was being used to run a pump in a shallow shaft. The engine was in a small station just a few feet back from the shaft. In working around the engine the gasoline was exploded and the fumes killed the men.

Passing hurriedly by the sections relative to leaving decayed timbers underground, providing for indicators on hoists, forbidding men riding with powder, tools, or timber, I come to section 19, which provides for ladders in all shafts, and that shafts over 200 ft. deep shall be divided into two compartments, one of which shall be partitioned off and set aside for a ladderway, and that landings shall be placed in manway at intervals of 30 ft. and at all working levels. When I first entered this work there were mines in this state where the men have been compelled to climb 600 and 700 ft. on perpendicular ladders, and the only way they could rest was by sitting on an 8 by 8-in. wall or end-plate. Not a platform in the entire distance. If a man should have fallen the chances are he would have stripped the ladder from one end to the other. Even the loss of a boot-heel by one of the men might cause the loss of many lives by knocking off one of the men below, he, in turn, knocking off others while falling. Some of the mines did not even have ladders in the shafts, and only the one outlet at that. The necessity for keeping at least one raise or winze connecting levels is certainly apparent to all.

The need of section 20, providing for more than one exit, was indelibly written on my mind when I was a boy. One of the mines in the county in which I lived, and at which I sorted ore, took fire, or rather the shaft-house which covered it did. The fire started in the change room which was directly over the boilers. Some powder had been placed on the top of one of the boilers to thaw. The flames quickly reached the powder and exploded it, knocking a hole in the boiler, and allowing the steam to escape, thus leaving powerless the engineer, who bravely stood at the throttle trying to hoist the cage. This mine had only one outlet. As a result the burning building over the shaft sucked all the air out of the mine and ten men were found on the 500-ft. level dead. Had that shaft been equipped as our law now requires, the manway would have been bulk-headed at least 25 ft. below the collar, and an adit run from that point to the surface. It would have been partitioned off, the hoisting compartment would have been upcast, and the fire would have pulled the fresh air in through the adit, thus giving the men fresh air to climb through.

Section 21, requiring sign-boards underground, is simple and only asks the same protection for men underground that most of the laws governing towns and cities give to their citizens when they enter a theater or to the traveler when he enters a hotel; that is that sign-boards directing men to different outlets shall be placed at each departure from the continuous course. Crews in different mines are constantly changing and as a result many are strangers in a strange place and should anything such as a mine fire happen, without these sign-boards many of the men would be liable to be trapped. The Tonopah Mining Co. has the most complete system of sign-boards of any mine in the state. If one can read, it is absolutely impossible for him to get lost. Passing sections 22, 23, and 24, which regulate the use of gasoline underground, use of chain ladders when sinking, and the use of guard-rails in front of shaft-levels, I come to section 25, which in my opinion is one of the most important sections in the law. This section provides for the placing of gates on all cages in shafts over 350 ft. deep, the same to be made of sheet iron or steel not less than $\frac{1}{8}$ in. thick, or of netting not less than of $\frac{1}{8}$ in. diameter, these doors to extend at least 4 ft. above the bottom of the cage, the doors to be closed when hoisting or lowering men, the only exceptions being when timbermen are riding on the

cage to attend to timbers that are being hoisted or lowered, or when cage is only used for sinking. No one will ever know the number of lives this device has been the means of saving, but it is known that since this provision has been put into effect, on four different properties in this state men have fainted when coming up on a cage loaded with men, and no damage has resulted. Without the gates it is reasonable to suppose that when the men toppled over they would have knocked off some of their companions. That has been the usual result in mines where gates are not provided.

I do not want to weary you, so will not stop to comment on sections 26, requiring a pillar of ground to be left next to the shaft, 27 and 28, which deal with the erection of structures over the mouth of shafts or adits. Sections 29 and 30 deal with the questions of ropes and cables. These two sections were recommended by the committee appointed

RESCUE HELMET USED BY BUREAU OF MINES.

by the American Mining Congress and the Mining and Metallurgical Society to frame a suitable mining law for the metal mines of the United States. These sections fully cover the matter of factor of safety and have been a wonderful help to us in our work.

Section 31 provides for the inspection of boilers by a qualified person at least every six months. There are only a few steam plants in the state, and in the absence of a regular state boiler inspector, it was thought best to so fix it that a check could be kept on them. Section 33 provides that when repairs are being made in any compartment of a shaft that only the hoisting necessary to make such repairs shall be done in that compartment. This makes it possible for a man to work in a shaft with some degree of safety and not have to keep dodging a cage. One busily engaged might in a moment of forgetfulness neglect to dodge and be seriously injured. This section fixes it so he, and he alone, can use the cage, therefore he knows where it is at all times.

Section 34, providing that wages shall not be paid on any premises used for the sale of liquor, probably looks out of place in a bill of this kind, but it was found necessary to furnish the miner a little protection on the surface. In a couple of places it was found that the manager of

the property had his office in a saloon. It was presumed that he and the saloon man were working together. So many congenial spirits meeting and receiving money in such a place resulted in some of them going home broke.

Section 35 is a very important section and the text reads as follows: "The operator of every mine, whether operated by shaft, stope, or drift, shall provide and maintain for every such mine a good and sufficient amount of ventilation for such men and animals as may be employed therein, and shall cause an adequate amount of pure air to circulate through and into all shafts, winzes, levels and all working places in such mine." The matter of ventilation is probably the most serious of the many that confronts the mine operator and miner. Good ventilation, all agree, is absolutely essential both from a humane and economical standpoint. The cost of production depends to a large extent on the working capacity of the men engaged in mining and getting out the ore, this working capacity is either advanced or retarded by the health of those engaged or by the degree of comfort with which men may exert themselves. The object of ventilation is the removal of impure air and the supplying of fresh air in its place. The required amount of air which should be forced into a mine is a question upon which men may well differ. Some mines are naturally cool, and in some the ground is such that very little gas emanates from it, and in some little powder is necessary. Now it is plain that under such conditions the same amount of air is not necessary, as in a place where the ground is naturally hot and the rock constantly emitting gas, or the rock is of such character as to require the use of large quantities of powder. It is hard, therefore, to lay down a general rule. Some writers on the subject recommend, and at present I am inclined to believe it the better method, that the fitness of the air to work in be judged by the amount of gas and oxygen in it, in other words, by quality rather than by quantity. Here, it seems to me, is a splendid field for the student in this university. You have every facility for making the proper tests, and this being a question with which every mining man daily comes in contact, ought, in my judgment, to be worked out by those who have chosen this as a life work. Data should be gathered upon which to base a judgment as to the quality of the air in which men may work without endangering their health.

Some of the mines in this state are ventilated by what is known as natural ventilation, secured by being connected with one or more shafts other than its working shaft, one being a downcast, the other an upcast. By means of raises and winzes connecting levels it is possible to conduct the air through the main portion of the mine. But as a general rule devices for mechanical ventilation should be erected at most mines, especially the deeper ones. The long prospect drifts or cross-cuts are frequently at such a distance from the main air-course that no benefit is derived therefrom, and it is expensive running raises to make frequent connections with levels when the drift or cross-cut shows nothing but waste. In many places where machines are used, reliance is on the compressed air, which furnishes the proper ventilation. My experience has been that this is unsatisfactory. In many of the mines thus ventilated, as soon as the men shoot, which is generally as they go off shift, the compressor is shut down and it is only started again when the other shift comes on, consequently the mine is hot and gassy. Compressed air for ventilation alone is found to be expensive, and bosses, as a rule, want the air turned off when the drill is not running.

In most of the larger mines the working places, so situated as to derive no benefit from the natural air-course, are supplied with air by means of fans or blowers. Many of the blowers are arranged so as to be used for blowing or exhausting the air through pipes. Where used as a blower the air is forced through the pipes to the point of discharge, forcing the smoke and bad air back through the passage way. In the exhaust system the foul air is sucked through the pipe and the good air comes through the passage way. There is some difference of opinion as to which is the better method. I am inclined to

think a mixture of the two could be practised successfully. When the face is full of smoke and gas, immediately after shooting a round of holes, it seems to me the exhaust system would be the better for the reason that it would be the means of keeping the smoke from the drift through which the men must tram. But when the men go in to work, I favor the plan of forcing the air to the face through the pipe; one reason is, you can force the air a considerable distance beyond the end of the pipe, while when used as an exhaust, the current is scarcely to be detected a few feet from the end of the pipe. Then, again, if the place is exceptionally hot and moist, and the men perspire freely, all agree that the working power of a person is greatly diminished and frequent rests are necessary. In order to keep down the heat in the body, radiation from the skin is necessary, and to produce that, it is necessary to have a fair current of air to absorb the moisture, and for that purpose air should be forced to them, and in order to get the best results by the cooling effect of evaporation, the air should be moving with some velocity.

Another great menace to the lives of the miners, is that slow and insidious disease known as miners' consumption. The very nature of the disease makes it difficult to combat, for it slowly but surely saps the vitality of a miner, and ere he is aware of it he has suffered a complete breakdown. Since the introduction of the machine-drill, and especially the hammer stope-drill, the increase in the number of miners affected by this terrible disease can be noticed. While the men on the drills are the most affected, many cases have been discovered among others who work in the mines. Trammers loading from the chutes are also compelled to breathe an atmosphere laden with dust. I know of one mine in this state where no machines at all are used in the stopes, yet the air is at all times filled with a flour-like dust. These fine particles enter the lungs and slowly do their deadly work. Strong young men will suddenly notice a shortness of breath, a little hacking cough, and gradual wasting away. Then at an age when a man is ordinarily at his best he finds himself unfit to work underground, and the knowledge gained by years of experience is lost to himself and the industry. These conditions I have seen with my own eyes, and one of the officials of a labor union in one of the southern districts told me they then had seven cases of miners' consumption that they knew of in that one local. Not a year goes by that the national government and the different state governments do not spend thousands of dollars to destroy germs, worms, and insects in order to protect the fruits and vegetables of our country; yet we never hear of the spending of a dollar to guard against a disease that is daily spreading its blight and sapping the heart's blood out of those brave men who take their lives in their hands, delving in mother earth to bring forth the golden treasure to be poured into the channels of trade. You can scarcely go into an up-to-date planing or flour mill without finding exhaust pipes running to every point from which dust is created. Exhaust fans are used to pull this dust from places where men are working and deposit it where it can do no harm. Why not try something like that in our mines? Some suggest using jets, sprays, and water machines. The question is, which is the best and most practical and what conditions should govern their use? I would suggest that since there is a United States Bureau of Mines, with a brilliant man at its head and by which wonderful work is being done for the coal mining industry, it would be well for Western men to show that they, too, are interested in this Bureau and its work and want it to be interested in them. Why should not this engineering club and every organization of like kind, the miners' unions, and the different mine operators' associations, write to this Bureau and ask it to take up this question from a scientific standpoint and give data upon which to base a law that will deal fairly and squarely with all. I feel confident they will do it. I have met Mr. Holmes, the director, and some of the young men under him, and know them to be honest conscientious workers, anxious to do all in their power to aid this industry. Let us give them a trial.

Mining at Treadwell, Alaska

Upon Douglas Island, opposite Juneau, Alaska, are three great and closely connected gold mines, the Alaska Treadwell, Alaska Mexican, and Alaska United. For the whole group F. W. Bradley is consulting engineer; R. A. Kinzie, superintendent, and E. P. Kennedy, assistant superintendent. Of the three mines, the Treadwell is the oldest,

which is upon a distinct ore-shoot about 2500 ft. south of the main orebody. The geology of the deposit has been frequently described and was well summarized by Oscar H. Hershey in the *Mining and Scientific Press*, February 25 and March 4, 1911.* Briefly, the ore consists of parts of a body of meta-gabbro, mineralized in connection with the intrusion of later albite-diorite dikes. The ore is considered to be of primary origin and is a simple gold ore treated by stamp-milling, amalgamation, concentration, and recently cyanidation of the concentrate. The great size of the orebodies have led to development of interesting and unusual mining methods.

NOTE.—* For the period beginning December 16th, 1910, and ending December 31st, 1911.
† This value is derived by adding the tailing value to the returns from the Mill.

Beginning at the north in Alaska Treadwell ground the ore-shoot at the surface extends from the south boundary nearly 1500 ft. north. The pitch is to the south so that at 1450 ft. in depth about 700 ft. of the ore-shoot remains in Treadwell ground. In the 700-Ft. claim at the surface the ore-shoot extended south to the shaft, roughly 300 ft., and from that point south 900 ft., and into Alaska Mexican ground 500 ft., the rock was too lean to work. The Mexi-

*See also 'Types of Ore Deposits,' pp. 157-171.

the Mexican comes next, and the United is youngest. They all operate upon one body of ore, though the Alaska United owns, in addition to the 700-Ft. claim between the Alaska Treadwell and Alaska Mexican, and the Ready Bullion mine,

NOTE.—Interest, &c., amounting to \$31,414.36 is included in the above Operating Profits.
Other profits amounting to \$111,762.06 were also earned, making a total profit of \$3,457,534.24.
Part of the ore crushed during the two years ending December 15th, 1909, was milled in the Mexican Mill and part in the Alaska United Gold Mining Co.'s 700 Ft. Claim Mill.

can ore-shoot, however, is itself roughly 1200 ft. long and pitches north. At 700 ft. deep in the 700-Ft. claim the two ore-shoots have met and ore is found throughout the length of the claim. On the 1250-ft. level ore is continuous for 2200 ft. The Ready Bullion ore-shoot is not so long, 400 to 500 ft., but as both the shoots are 300 and more feet in width, the amount of ore is enormous. It is interesting to observe that it costs approximately \$300,000 to open each new level and that six years elapse from the time it is opened until it is abandoned. The methods of mining employed have been described by T. A. Rickard† and others.

At the close of 1910 the total measured ore reserve in the Alaska Treadwell was about 7,000,000 tons, of an average value of \$3, whereas the average value of the ore milled to that date was \$2.40, of which 85c. per ton had been paid in dividends. The report of the senior company for the year 1911 is not yet available, but from recently issued reports of the Alaska Mexican and Alaska United

companies, the accompanying tables have been taken. The historical statement of ore reserves in the Mexican mine shows a present total of 980,025 tons, worth \$3.14 per ton, as against an average reserve since 1901 of 620,825 tons, worth \$3.24. The ore milled last year amounted to 227,081 tons, worth \$3.26, the latter figure being obtained by adding the recovery to the tailing loss. The average of all ore milled has been \$3.11. Details are shown in Table I. In the case of the 700-Ft. claim the present reserve is 1,387,076 tons, worth \$3.08, as against an average of 394,913 tons, worth \$2.57. The tonnage in 1911 was 225,403 and the average value \$2.52. The average value of all ore sent to the mill since 1901 has been \$3.11. Corresponding figures for the Ready Bullion mine are shown in Table II. A comprehensive view of the business of the two companies may be obtained from Tables III and IV. The Alaska United had paid, up to 1912, \$837,930 in dividends. Hoisting is now done through separate shafts, but the 700-Ft. claim shaft has been re-timbered to the 1600-ft. level of the Treadwell and is to be used as a main central shaft for the three mines. The equipment will permit of hoisting 5000

Interest	•0012
Balance—Net profit for period	1-0909
	\$2-8657

erected and power will be sent from the Sheep creek plant to Nugget creek during the period of construction. When the new plant is completed a large part of the power will be used in pumping tailing from the various mills into underground slopes in order to fill them. The year 1911 was a busy and successful one with results quite in keeping with the quiet efficiency that has long characterized operations at these great gold mines.

Japanese Copper Production

The total copper production of Japan for the year 1911 amounted to 115,308,000 lb., equal to an increase of 5,609,333 lb. over 1910, and 30,520,000 over 1907. The value of the 1911 product was \$13,469,000, an increase of \$559,500 over that for 1910. Detailed figures for the five leading producers are given below in pounds:

	1911.	Increase or Decrease.
Ashio	16,964,227	+ 1,332,901
Besshi	15,145,070	+ 301,904
Kosaka	13,245,527	- 836,475
Hitachi	12,608,761	+ 1,863,411
Osarazawa	4,344,521	- 500,973

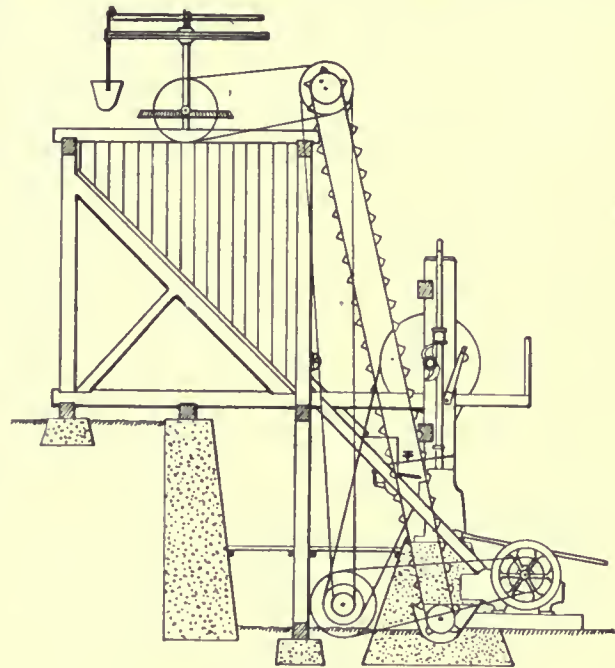

The increase in the case of the Hitachi is especially remarkable, since it brings this mine into the leading class. Improvements and extensions have kept the Ashio mine at the head, though the race between it and the Besshi for first place is becoming keener. The present will undoubtedly be a good year for the Japanese copper mines. Since January 1 the price of copper manufacture has increased 20% and the demand is good. The wire mills are especially busy.

COPPER smelting equipment is in course of erection at the Kalatinsky mines in the upper Isset district, Russia. The ore is a cupriferous pyrite containing as high as 3% copper.

An Unusual Type of Mill

By W. G. FRENCH

In the 10-stamp mill of the Fort Bidwell Consolidated Mines Co., at Fort Bidwell, Modoc county, California, the arrangement of the crushing machinery is unusual, and a description of its operation will be of interest to quartz-mill operators. The topography and other conditions existing at the millsite necessitate a departure from the usual type of stamp-mill construction and arrangement of the machinery. The ore from the mine is delivered directly to the mill-bin by an aerial tramway one-half mile in length. This ore-bin consists of two sections, one for the

ARRANGEMENT OF CRUSHER AND STAMPS.

tramway delivery, the other for the rock-crusher product or battery feed. The entire tramway delivery is conducted from the bin to the crusher, the jaws of which are set for an opening of two inches. No sizing by grizzlies or screens is employed. The unusual feature of this mill is that the rock-crusher is placed on a level with the apron plates, and to one side of the mortar. By reference to the sketch it will be noted that the crusher is belted directly to a driving pulley on the line-shaft, which runs beneath the feeder floor. Driving pulleys on this shaft operate the 5-stamp batteries and also the elevator. The tramway is also operated from a countershaft belted to this line-shaft. The entire product from the crusher is handled by means of a belt and bucket elevator, and delivered to the battery feed section of the ore-bin, whence it is delivered by the usual method to the stamps. Some of the main features to be noted in this arrangement of mill machinery are that it obviates the use of large timbers in construction of bins and eliminates the ever-present danger of oil coming into contact with the ore, through careless handling about the crusher when the crusher is set directly over the ore in the bin. When the necessary height or fall is not obtainable for the usual type of installation this method will, in some cases, solve the problem, as less fall is required. In most cases the millman can attend to the operation of the crusher, thereby reducing the cost of mill labor.

PERMISSION has been granted by the authorities of Puerto Cabello to Eusebio Rodriguez and Esteban Sivisa to exploit a goldfield, which, according to a document filed with the public registrar, they have discovered in Borburata, a small village in the suburbs of Puerto Cabello, Venezuela. They claim that the goldfield is 200 hectares (494.2 acres) in extent and has much gold quartz, which also contains other metals.

Appropriations for Mining

Funds for the United States Geological Survey and the Bureau of Mines, the two great federal organizations in which mining men are interested, are appropriated in what is known as the Sundry Civil Bill, originating in the Committee on Appropriations, of the House of Representatives. This bill carries, of recent years, over \$100,000,000 annually, covering a large part of the Government's field of activity in civil affairs. As reported this year the total proposed to be appropriated is \$109,577,414, and the bill makes up a book of 182 pages. While the amounts fixed in the report of the committee are not final, Congress has a deep rooted objection to revision downward, and the total is likely to be increased rather than the reverse.

The items for the Geological Survey are as follows: Office of director, \$35,340; scientific assistants, \$29,900; skilled laborers and temporary employees, \$20,000; topographic surveys, \$350,000; geologic surveys, \$300,000; mineral resources of Alaska, \$90,000; chemical and physical researches, including potash investigation, \$40,000; preparation of illustrations, \$18,280; preparation of the report on mineral resources, \$75,000; gauging streams and water-supply studies, \$150,000; purchase of books, \$2000; engraving and printing geologic maps, \$110,000; topographic surveys in national forests, \$75,000; making a total of \$1,295,520. In addition there is appropriated to the public printer \$145,000 for engraving and printing of Survey reports.

For the Bureau of Mines the proposed appropriations are: General expenses, \$66,100; general investigations of mine explosions, methods of mining, etc., \$320,000; analyzing and testing fuels, \$135,000; mine inspector of Alaska, salary and expenses, \$6500; purchase of books, \$1500; purchase of land and construction of railway siding for headquarters for mine rescue cars, \$4000; making in all \$533,100. A special appropriation of \$100,000 for investigations in the metalliferous mines of the West was asked but not granted by the committee. An effort will be made to amend the bill on the floor of the House so as to obtain this sum for the work.

Copper Queen Miners' Benefit Association

Benefit associations for the employees of large corporations are not new, but the results secured by the association maintained by the employees of the Copper Queen Consolidated Mining Co. have been so uniformly successful as to make a short account of the plan and results attained of general interest. We are indebted to S. W. French, general manager for the Copper Queen company and chairman of the board of directors of the benefit association, for the following data. The association is governed by a board of directors, of which the general manager is chairman, four members are heads of departments of the company and four members are workmen, elected by ballot by the members of the association. The funds of the association are provided by a yearly contribution of \$25,000 by the Copper Queen company and a contribution by members at the rate of 2% of their wages, such contribution during 1911 amounting to \$40,303. Benefits are paid for loss of working time due to accidents at the rate of half pay for each working day lost from this cause. For loss of working time due to sickness, half pay is granted for each day after the first seven days. Neither accident nor sickness benefits are continued for a longer period than one year. For serious injury, from one-half to two years average pay is granted, according to the nature of the injury. In the case of death from accident, two years average wage is paid, and for death due to sickness, one year's wages. During the year, 6.33% of the membership received benefits; 4.96% being accident benefits and 1.37% sickness benefits. At Bisbee approximately 70% of the men are members of the association, and at Douglas 60% are members. An interesting feature of the work of the association is that the cost of administering the benefit fund of over \$66,000 was less than

\$2000, since the directors serve without pay, while the duties of superintendent and assistant superintendent are combined with those of paymaster at the Bisbee and Douglas plants, the former received \$50 per month and the latter \$25 for this service. This is in sharp contrast to the report of the New York Employers' Liability Commission in 1910, where it was shown that of the premiums paid by employers to liability insurance companies less than 37% is paid to the injured employees, over 63% being paid to attorneys, claim agents, and cost of administration. In this case over 96% of the contributions is paid to the injured members. The work of the association has been satisfactory and without friction, perhaps largely because of the wise policy of the company in making no effort to secure members for the association, thus emphasizing that it belongs to the employees and is under their direction.

May Metal Review

By MISHA E. APPELBAUM

During the greater part of May copper continued to advance, principally due to domestic buying. Toward the close of the month, however, Europe had again turned buyer and another sharp advance took place, because of this. Quite a cry has been raised in some corners that copper is being manipulated, but as I stated some time ago in these columns, the advance in copper is due to the fact that none of the consumers expected the metal to go higher than 14 to 15c. When the market reached that figure they entirely withdrew, and after watching it for a little time and being absolutely in need of copper, tried to buy at the then prevailing prices without much success. The principal refineries and producers being sold out up to about the end of August, are unable to supply the spot demand, which, while not great, is enough, considering the small supply, to cause further sharp advances.

Everyone has also been predicting that on account of the high price of copper, the consumption will fall off. Past experience indicates that 4, 6, or even 18 months of high copper prices does not affect the consumption; similarly, a few months of the low copper prices does not stimulate consumption. In order for the consumption to be stimulated by low prices or to be affected by high prices, they must prevail for at least two years. Personally, I feel that if copper remains at 18 to 20c. for several years, the production will be pushed and many mines will be opened, so that in time the world supply of copper will be much greater than the consumption. Such an increased supply usually comes on the market at the time when consumption shows signs of falling off. This has been the history of the copper market for the past twenty years, and I believe that in this case history will repeat itself. However, it is safe to say that, so far as the next few years are concerned, in view of the business outlook, copper prices, irrespective of the final adjustment, will rule on a higher level, and the sooner the consumers realize this fact the more profitable it will be for them. Financial conditions are sound, and conservatism is the word. With this policy I believe a period of a few years of prosperity has begun, and I do not believe that political conditions will interfere. Both parties realize the conservative temper of the masses and will frame their platforms accordingly.

ZINC mines at Franklin Furnace, in Sussex county, New Jersey, continued their important output of metal during 1911, according to the report by H. D. McCaskey of the U. S. Geological Survey. The New Jersey Zinc Co. treated 306,168 short tons of ore at its concentrating-plant and shipped 67,896 tons of crude ore to smelters. Figured as metallic zinc, the total recoverable output was 154,890,900 lb. of spelter, valued at \$8,828,781, an increase of 17,535,681 lb. over the production in 1910. The crushing plant at the mine has a capacity of 2240 net tons in 24 hours and the separator a capacity of over 1100 tons.

Discussion

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Insertion of any contribution is determined by its probable interest to the readers of this journal.

Free Use of Timber from Public Lands

The Editor:

Sir—I note in your issue of March 30, 1912, under 'Concentrates' an item about the cutting of timber on public lands which says "there is no authorization to cut any small or limited amount of timber under this act without a permit." I quote from the circular of the Department, dated February 10, 1900: "Rules and Regulations Governing the use of Timber on Non-mineral Public Lands in certain States and Territories, under the Act of March 3, 1891 (26 Stat. 1093), as Extended by the Act of February 13, 1893 (27 Stat. 444)."

Sec. 3 says: "Settlers upon public lands and other residents of the states and territories above named may procure timber free of charge from unoccupied, unreserved, non-mineral public lands within said states and territories, strictly for their own use for firewood, fencing, building, or other agricultural, mining, manufacturing, or domestic purposes, but not for sale or disposal, nor for use by other persons, nor for export from the state or territory where procured. The cutting or removal of timber or lumber to an amount *exceeding* in stumpage value of \$50 in any one year will not be permitted, except upon application to the Secretary of the Interior, and after granting of a special permit.

Except as above provided, it is not necessary for actual residents to secure permission to take timber from public lands in said states and territories for the purposes aforesaid. The exercise of such privilege is, however, subject at all times to supervision by the Department with a view to such restrictions as may be deemed necessary."

De Lamar, Idaho, May 3.

ERNEST V. ORFORD.

[The circular quoted by our correspondent is an old one and has been superseded. The regulations as to the free use of timber from the public domain were last week discussed in full detail by T. D. Woodbury, assistant district forester in charge of silviculture.—EDITOR.]

Mr. Roosevelt and the Japanese

The Editor:

Sir—In your editorial, May 18, you condemn reference to Mr. Roosevelt's Japanese message. To me it seems so important for every voter in the United States to understand this matter, that I cannot help thinking that the important point has escaped your attention. Mr. Roosevelt threatened to use the Army and Navy of the United States to force California to grant the Japanese rights in the schools which he said were *guaranteed to them* by treaty. It seems a vital question whether the Senate and President could by treaty grant rights in our public schools which they could not grant by direct legislation. Elihu Root, when referred to, said that a treaty was beyond question the supreme law of the land, but he stopped there. It was not till public interest in the question had subsided that the Boston *Transcript* asked Richard Olney for his views. Mr. Olney in reply (published in the Boston *Transcript*) said that when Secretary of State under Mr. Cleveland he was the author of the treaty in question, and that he incorporated in the treaty a section that secretaries of state were accustomed (because of the dual character of our government) to put in similar treaties. He then quoted the section, which was in substance that any rights granted by the treaty were subject to all municipal laws and police regulations. He concluded by saying that under the treaty the Japanese could claim no rights in our public schools except such as were granted by the municipal

laws. The point that I wish to call your attention to is this, that when Mr. Roosevelt said that the treaty granted them rights in the schools, either he was attempting to discuss an important treaty without having read it, or he deliberately misrepresented the facts to the American people. It is a great risk to elect for President a man who is superficial and inaccurate as to his facts.

H. W. REED.

Salt Lake City, May 29.

[Our correspondent has slightly mistaken the purpose of our comment. We have no desire to argue the question whether Mr. Roosevelt should or should not be elected President. There are grave differences of opinion upon that point even among those who greatly admire him. Neither is the matter of aliens in San Francisco schools now a question for debate. So far as we know no alien has any *right* to entrance in the public schools, and all aliens are admitted by courtesy. The mixing of adults and infants in the same schools is bad pedagogy and likely to lead to bad morals; but to draw the line against a race rather than individuals is contrary to the spirit of our institutions and breeds trouble. To discriminate against one alien people and not another is bad manners as well as bad policy. It is the President's duty to use all the force at his command to protect aliens in whatever rights are conferred upon them by treaty, though interpretation of those rights is by no means wholly in the President's hands. However, what we said in the paragraph of which complaint is made was that "stirring up race prejudice is disreputable politics"—surely there can be no difference of opinion as to this. It cannot matter greatly whether a President was right or wrong in a particular interpretation of his duty, whether a given man should or should not be elected to office, if an appeal to underlying and unreasoning race prejudice must be made to defeat him. Rousing the passions of the multitude by such means is demagogic to the last degree. We do not believe our correspondent means to disagree with us as to this, however much he may distrust Mr. Roosevelt.—EDITOR.]

Edison and Ore Dressing

The Editor:

Sir—Referring to recent press comments concerning Thomas A. Edison's efforts in the low-grade ore problems, will you kindly state that he is not working upon a solvent, as seems to be the prevailing impression. Over a year ago my company interested Mr. Edison in the question of an improvement in concentration, utilizing his fine-grinding rolls as the basis for the prevention of sliming. During the past year considerable progress has been made in making higher savings from the finer material, and also in the general treatment of complex ores, separating the lead, zinc, iron, and copper by a system of concentration. These experiments have been conducted in a large 100-ton unit in his laboratory at Orange, but there is yet considerable to be done before we will feel justified in erecting a practical plant.

Mr. Edison does not anticipate entering mining or milling; but by his arrangement, if this improvement works to his satisfaction, my company is to attempt to commercialize it by erecting a large plant somewhere in the West, so that a thorough demonstration of its practicability can be made before offering the improvement to the mining public. Mr. Edison has made no claims whatever, as he is still experimenting on the problem. What I desire more to impress is that he is not working upon a solvent; simply an improvement in concentration.

HENRY B. CLIFFORD.

New York, June 10.

DREDGING in New South Wales continues to steadily decline in output, the yield for 1911 being 23,364 oz., a decrease of 5296 oz. during the year. During 1911 the number of bucket dredges at work was 20, handling 5,122,476 cu. yd. of an average value of 7¼c. per cu. yd. The 9 pump-dredges handled 1,260,429 cu. yd., of an average content of 7.6c. per cubic yard.

Special Correspondence

NEW YORK

EL PASO AND GUGGENHEIM EXPLORATION CO. FEATURES OF THE MARKET.—PROMISING FUTURE OF BUTTE & SUPERIOR.

The principal feature of the mining market in New York, in the way of active trading, is the effort being made to distribute stock of the El Paso Consolidated of Cripple Creek. Besides the active trading in the Street, a plan of consolidation of the leading properties in Cripple Creek is being outlined in the daily press. A corporation with a capital of possibly \$35,000,000 is to be formed, with El Paso and other leading properties going into the merger. It is claimed that the new concern will have an output of probably 20% of the entire gold production of the country. El Paso has paid about one and a half millions in dividends, and it is stated that some 400,000 shares of the stock has just been sold to certain German and Swiss banking interests. The shares of the Guggenheim Exploration Co. are now being traded in on the floor of the New York Stock Exchange, and the public is trying to analyze the value of the various holdings of this concern. The Exploration company has sold out all of its Esperanza holdings, from which it at one time received a very large revenue. Its holdings in the other Guggenheim companies, Utah Copper, Ray Consolidated, Chino, Yukon Gold, and Braden Copper, are not hard to appraise, as active markets are made in all of them; Braden Copper especially having been a favorite with traders during recent weeks. There has been a considerable absorption of Yukon Gold during the past few weeks. It is expected that the showing for the present year will be very much—possibly 50%—better than it was during 1911. The Yukon Gold company has obtained control of the placer fields at Iditarod, Alaska, and these holdings are looked upon as adding considerable value to the company's property.

The Phelps-Dodge shareholders are participating in the prosperity due to the advance in copper metal, receiving the regular dividend of \$2.50 per share and \$2 added dividend, both being payable June 28. It is said that this distribution of profits comes from earnings accumulated before the last advance in copper, and that the latter half of the current year will probably see a considerably larger disbursement made.

The stubborn skeptics on copper conditions are having their attention directed to the increased dividends as an unanswerable argument as to the position of the copper metal. In the meantime, however, the buying of copper shares continues sporadic.

The followers of Porcupine have continually pointed to the Hollinger and the Dome as the two properties that would redeem the camp. The Hollinger is evidently laboring under some financial difficulties. It owes \$125,000 to the original Timmins-McMartin-Dunlap syndicate, and it is now proposed to issue 50,000 shares of treasury stock; 12,500 shares to be taken by the syndicate in liquidation of the company's indebtedness to them, and the remaining 37,500 shares to be offered to the stockholders at \$10 per share. Inasmuch as the stock is selling in the open market at \$9.50, it is a little difficult to see how the stockholders can be expected to absorb this treasury offering very readily.

There is a very interesting rumor afloat in regard to a group of the independent properties of Butte, including the Tuolumne, Pilot Butte, Butte & Superior, and the Butte Ballaklava, anent a merger of these and one or two properties of minor importance. There has been some steady absorption of Tuolumne stock by Boston interests, said to be for the account of William A. Paine, of Paine & Webber. The House of Paine & Webber has always had a very large share of the Boston copper business between the Lake country and Boston, and traders are hoping that the present rumor will prove to be founded on fact.

Butte & Superior was particularly fortunate in developing its mine at a time when the market in zinc began its rise. A large amount of money had been expended on the Butte & Superior ground in the search for a body of commercial ore when, in sinking its shaft, the company ran into a body of bonanza zinc which is said to show ore continually from the 500 to the 1600-ft. level. The present ore reserves are estimated at 2½ million tons, 22% zinc. At the present prices for zinc, Butte & Superior is one of the most spectacular properties ever developed in the camp.

The real hope for the proper revival of mining interests in the near future lies in Mexico. While the stories of the war correspondents still picture a very much unsettled state of affairs, the railway lines report that the refugees who have been seeking sanctuary in San Antonio are returning to Mexico; work is being commenced on the extensions of the Mexican National railway, and the making of the loan by Speyer & Co., mentioned in a previous letter, is having a reassuring effect.

BOSTON

LAWSON INTERESTED IN AFRICAN COPPER FIELDS.—INCREASE IN COPPER DIVIDENDS.—BOOM IN BUTTE & SUPERIOR.

The African copper fever has infected Thomas W. Lawson. A few days ago he dispatched Charles C. Clapp on the *Canopic* from New York to Naples, where Clapp will meet a party of mining engineers. They will get up their equipment and start for Mombasa, on the east coast of Africa, whence they will travel inland to the copper fields. It is said that Lawson desired to accompany Clapp, but as he is a red-hot Roosevelt champion, and is also a candidate for the United States Senatorship to succeed Crane, his political engagements kept him from carrying into Africa a personally conducted copper campaign. Lawson wishes to emulate Roosevelt in his African adventures. He is looking for a copper mine, while Roosevelt's quarry consisted of lions and other wild beasts.

The Lake Copper Co. is on a steady shipping basis. Some 300 tons of ore go to the mill daily from its stock pile. The ore assays about 28 lb. of mineral, netting about 18 lb. per ton. This is a satisfactory showing, because it maintains the average of the Lake mine. The management expects to start shipments from its underground workings, and to work these shipments up to 800 tons per day by fall. Lake is no longer watched every day and every hour of the market, for some new sensational developments, as was the case something over two years ago, when it was a brilliant prospect. The mine has now reached the tenth level and the ground holds uniformly with that in the upper levels. The Lake lode, which created such a sensation in the Boston market, still keeps people guessing as to which way it is going. On the seventh level this famous vein turns toward the North Lake mine, but the tendency of the lode has been to wave or roll first one way and then the other, its general course being in the direction of the South Lake mine. The developments of the lode are of absorbing interest to both these neighboring properties, one to the north and the other to the south. There are also other South Range properties whose managements are narrowly watching Lake developments, hoping that the Lake lode will come into their ground. It is one of the interesting situations which are always to be found in the Lake copper country.

Almeek has increased its quarterly dividend rate from \$4 to \$5 per share, placing the stock upon a \$20 per share annual rate. At this rate the parent Calumet & Hecla will receive around a half million dollars annually in dividends from this most interesting and important subsidiary. Almeek's dividend course has been upward and onward with each quarter. Nine months ago it started paying dividends on a quarterly basis of \$2 per share; three months later this was increased to \$3; three months ago the rate was increased to \$4; now it is \$5 quarterly. The stock is inactive on the Exchange and will probably always re-

main so. It is selling around \$360 per share, which makes it a net dividend-payer of 7.2%. It is now said that if the 17c. copper market continues there will be another increase in the dividend rate of Quincy to \$1.75 per share or \$7 per year. At the last quarter dividends were increased from \$1 to \$1.25 per share quarterly, the increase being based on 14½c. copper. Quincy is earning around \$14 per share on 17c. copper. The Anaconda may also increase its dividend rate at the meeting on June 25, as it has increased production and has brought costs down to nearly 9c. per pound, almost rivaling the lowest costs of the porphyries. It is expected the rate will be advanced to at least \$3 per year. Inasmuch as Anaconda is earning \$5.50 per share on the present high copper market, evidently the directors could, if they so wished, make the dividend even \$4 per year. Anaconda can pay \$3 per year on the present market and add at least \$10,000 annually to its surplus. Another dividend increase which will exert a good effect in market circles is expected at the directors' meeting, July 20, of the Tennessee Copper Co. They will probably place the stock on a quarterly basis of \$4 per year. The last dividend, a semi-annual one, was \$1.50 per share, declared on February 20. The disposition of copper companies to share high-priced metal prosperity with stockholders without delay will do much to attract the public into the market, and is one of the best signs of the times in copper.

Not reconciled to the United States Supreme Court's decision as an ultimatum, A. S. Bigelow, of Boston, promptly petitioned the court for a re-hearing of the case of the Old Dominion Copper Co. of New Jersey against him. Bigelow hoped by this course to at least gain a considerable amount of time, as it was not thought that the Supreme Court could get around to the case until next fall. But the court has acted without postponement, and hence Bigelow has no longer any hope in that direction. It is said now that he will fight the validity of the 'trust receipt' creation and will question the rights of receipt-holders to share in the distribution of assets put up by him with the New England Trust Co. The belief in Boston is that Bigelow is now making a vain fight, after having held out for ten years and availed himself to the limit of the law's delays. His securities put up with the trust company will undoubtedly be liquidated as soon as the formal order is received from Washington, and with that will end what has been in many respects one of the most remarkable cases ever tried in the history of the courts. Bigelow has figured in something like \$15,000,000 worth of copper law-suits in the courts, his cases ranging from the lowest to the highest courts.

The Butte & Superior market boom continues in Boston. Butte & Superior has about 3,000,000 tons of developed ore running 22% zinc, with high content in silver, and within the boundaries of present development work it can be depended upon to increase this to at least 5,000,000 tons. The new mill is saving nearly twice as much of metal content as the old. The company is fully financed, having sold, in April, 30,000 shares of stock at \$27.50 per share for the treasury. On the present price of spelter, and with its capacity advanced to 1000 tons per day, Butte and Boston authorities agree in estimating the net earnings of Butte & Superior at approximately \$3,000,000 per year. Even this estimate does not include the revenues received from by-products, which amount to about 75c. per ton. Butte & Superior lies to the north of North Butte, and was for a time considered to be outside of the mineral—and especially the copper—zone of Butte. The company, encouraged by the remarkable discovery and development of the Edith May vein in North Butte, began the search for copper in its own property. It failed to find copper of commercial extent, though the management put down a shaft 1600 ft. in quest of it. It found some copper, but the ore changed into zinc—good clean zinc which is exceptionally amenable to treatment—and today Butte & Superior stands out before the world as a copper failure, but one of the biggest zinc successes in the world. The company's developments have been among the most sensational in the

history of Butte. Boston traders are freely talking \$75 per share for the stock. Nothing like the remarkable run it is making on the Exchange has been known since Lake was advanced to \$94 per share. In the south of the district, Davis-Daly and Butte Central are demonstrating that the boundaries of the rich mineralized section extend beyond the estimates of a few years ago. Davis-Daly has found a body of rich copper ore on the 1900-ft. level, and Butte Central has entered the copper zone at around a thousand feet in depth. Both Butte Central and Davis-Daly are evidence of the presence of the Ramis fault-zone, the largest fault-zone in Butte, which has given the district a considerable production to date. Butte Central has the famous shear-zone crossing its property and Davis-Daly, in the vicinity, presumably has it at greater depth. With Butte developing its mineralized boundaries both to the north and south and with its deepest workings to be developed to nearly double their present depth before its shafts are as deep as those of Calumet & Hecla and Tamarack, it is no wonder that engineers say it has many years to go before reaching the height of its productive career.

LONDON

VENTILATION IN LONDON.—USE OF OZONE.—POTASH AND KELP.

The ventilation of metal mines is receiving so much attention nowadays that any novelty bearing on the subject attracts attention. For instance, the new ventilation apparatus installed on the Central London railway is interesting. The circumstances and conditions are somewhat similar to those in mine workings. The Central London railway, commonly called the 'Tube,' is 7 miles long, with 13 stations, and is from 60 to 100 ft. below the surface. There are two lines, each contained in a tube 11 ft. 8 in. diameter, and at intervals connected by cross-overs. Hitherto the ventilation has been effected by the passage of the trains and by an exhaust fan near the British Museum; and in the night hours during which no trains run, by an exhaust fan at the western end at Shepherd's Bush. In spite of all these precautions, the atmosphere is depressing and unpleasant, but, as usual, the cause is difficult to analyze. It is held generally to be the result of organic constituents of the air due to the continuous passage of large numbers of people. The company therefore decided to adopt the 'ozonair' apparatus for introducing sterilized air containing a small proportion of ozone to give it an oxidizing effect. At twelve of the stations an independent apparatus has been provided. The air supply is first filtered in the usual way, and then passed between fine metallic gauze and mica sheets across which discharges are caused to pass by means of a 5000-volt alternating current. The current of air passed through averages 6000 cu. ft. per minute at 10 of the stations, and 10,000 and 18,000 respectively at the other two. The air is sent along mains having a cross-section of about 3 sq. ft. made of galvanized mild steel, the shape of the section depending on the space available. Some of the air is discharged at five or six points along each platform and 7 ft. above them, and the remainder into the tunnels about 40 ft. from the station in the direction the trains run, to be drawn along by the train to the succeeding station.

For several decades the Stassfurt deposits in Germany have provided the bulk of the commercial salts of potash, chiefly kainite, a double salt of potassium chloride and magnesium sulphate. The imports of this article into the United States have been large, and the imposition of an export duty by Germany greatly upset the American trade. In Norway and Japan the old kelp industry is being revived. Until the invention of the Leblanc process for the manufacture of alkali from common salt about a hundred years ago, practically the whole of the alkali and alkaline salts used in Europe were derived from kelp, that is, burnt seaweed. Along the western coasts of Ireland and northern Scotland, and also in Normandy, the Celtic population was actively engaged in its manufacture. The Gulf Stream continually carries great quantities of the marine vegetation to these neighborhoods, and its collection is a simple matter.

The amount of valuable salts is larger in the deep-sea vegetation than in the weed that grows in the shallower waters around the coast, so that attention was usually confined to the ocean drift. Unfortunately the methods of treatment were not altered to keep pace with scientific requirements, and the industry gradually shrunk to nothing. There is no reason why it should not be revived, for the scientific treatment for the extraction and separation of the salts is not really troublesome or complicated. The kelp prepared in Scotland averaged 23% potassium chloride, 7% potassium sulphate, 17% sodium chloride, and 4% of sodium and potassium carbonates, together with 45% of insoluble matter. It is probable that some other process might be adopted instead of the old-fashioned burning; maceration and retorting have both been suggested and tried on a small scale. Seaweed also contains iodine salts, and the production therefrom of iodine is at present the only commercial application of the vegetable kingdom.

BUTTE, MONTANA

WORK OF THE ANACONDA.—LOSS AT THE BUTTE-BALLAKLAVA.—NORTH BUTTE PROFITS.

The Anaconda Copper Mining Co.'s annual statement for assessment purposes has been filed and the figures, given under oath, show the vast sum of money expended and the amount realized from the properties of the company. The net proceeds this year, on which the company will pay taxes, is \$10,525,729.82, as compared with \$5,096,445 in the previous year. This is the largest profit reported in any year during the past five, and may be accounted for in two ways. First, by the many new economies put into use during the past twelve months, and, second, by the fact that for the past six months the production has been greatly increased and copper has been sold at a higher price than for a long time. The fact that the company has a little more than doubled its net proceeds in the past twelve months is clear indication of the prosperous condition of the copper industry. The statement shows that there were 4,319,994.77 tons of ore extracted, of a value per ton of \$8.86, giving a gross yield of \$38,277,753.14. The cost per ton for mining was \$3.709, and the cost of transportation to the Washoe smelter at Anaconda and the smelter at Great Falls was 0.308c. per ton per mile. The total amount of money paid for transportation was \$1,332,464.55. The cost of reduction was \$1.673 per ton, and the total amount expended in reduction was \$7,227,773.93. The company spent for labor \$13,440,936.66, while \$9,809,629.07 was paid for machinery and supplies. The marketing charge, including seaboard refining, freight, and selling charges, was \$3,168,993.04, making the total costs \$27,752,023.32. There is one item of \$9,809,629.07 for machinery and supplies, that will give some idea of the amount of money the company has put into new and modern equipment during the past twelve months.

The Butte-Ballaklava company was operated during the past year at a loss of \$45,956.94, according to the report filed with the county assessor by C. W. Newton, superintendent. It is reported that but 310 tons of ore was extracted during the twelve months, which yielded \$5.68 per ton, the total gross yield being \$1760.71. The cost of extracting the ore was \$775, and there was paid for transportation \$32.80. The cost of reduction is put down at \$930, while there was expended for labor \$40,290.90 and for supplies \$5688.95. The company is not shipping any ore at the present time. A small amount of development is going on, both on the 1400 and 1600-ft. levels, but not any ore of shipping grade has been found. For fully six months of last year the company did not attempt to do any mining, but after the fire in the High Ore had been extinguished, a considerable amount of money is said to have been expended in the shaft repairing damage alleged to have been done while fire fighting was in progress. The development now being done is in ground not in dispute with the Anaconda company and the management has strong faith in opening a body of ore on the 1600-ft. level.

The Tuolumne company is still negotiating with the Anaconda company for a lower rate on smelter charges. The present rate is \$3.25 for second-class ore and \$5.25 for first-class. The Anaconda company has offered a reduction, but Edward Hickey, president of the Tuolumne, considers that a still greater concession can be made and negotiations are still pending. In the meantime the Tuolumne is shipping about 300 tons of first-class ore per day. Development is being extensively carried on at the 1600 and 1800-ft. levels and the ore thus opened will enable the company to increase production. There will be a meeting of the directors on July 1, and at that time it is expected a dividend will be declared payable in August. Some of the directors, in discussing the matter, favor a 25c. rate per quarter, while others think that 15c. will be the amount ordered, and that, if in another three months the conditions warrant, the rate can be raised to 25c. The Tuolumne has now \$140,000 cash in the treasury, with no indebtedness.

The North Butte company net proceeds for the year are given at \$986,212.82, an increase of about 65% as compared with twelve months ago. The report shows that 411,908 tons of ore of a value of \$10.164 per ton was extracted. The cost of mining was \$4.19 per ton, and the reduction cost was \$3.426 per ton. The construction charges amounted to \$13,421 and the total expenditures \$3,200,524.32. The company paid during the year for the transportation of its ore to the smelter \$49,360.05, the cost per ton per mile being 0.12c. Development was carried on at the 2000, 2200, 2400, 2600, and 2800-ft. levels, but up to the present time no large or important bodies of ore have been found. On the Snowball vein on the 2200-ft. level the ore is still high in copper and silver, and it is from this level a large portion of the ore going to the Washoe smelter is being mined. The ore reserve as given in the annual report is being maintained.

The Raven Copper Co. was operated at a loss during the year ended May 31 of \$68,815. In explanation of this, however, it should be stated that the mine work was confined to development and the only ore shipped was that taken out in the course of development. Shaft sinking is now going on and the management is quite confident that good ore will be found at depth. The report filed for assessment purposes shows that 490 tons of ore was extracted, giving a gross yield of \$27.72 per ton. The reduction cost was \$6.06 per ton. The sum of \$46,760.77 was expended for labor, while \$4093.85 was expended for machinery and \$27,309.12 for supplies. The Butte & Superior concentrator has not yet reached its capacity of 500 tons per day, but in the course of a week everything is expected to be running so smoothly and satisfactorily that the full amount will be handled. A committee has been formed with Edward J. Carter as chairman, for the purpose of safeguarding the interests of the holders of Stewart Mining Co. stock.

JOHANNESBURG, TRANSVAAL

RANDFONTEIN CENTRAL.—UNFAVORABLE RESULTS OF CONSOLIDATION ON THE WESTERN RAND.

A mine on the Rand that has of late been commanding attention is the Randfontein Central, that occupies, on the farthest extremity of the western Rand, a similar position to that of the East Rand Proprietary Mines on the eastern Rand, its area being about three thousand acres. One feature of attraction is its huge mill of 600 stamps with the necessary equipment for secondary treatment which, by the way, has never been fully employed. This mill is situated at the northern end of the property, the southern portion being served by four other mills, each equipped with cyanide plants and formerly known as the Randfontein South. At the beginning of last year the whole of the Randfontein properties were combined under the title of Randfontein Central with an issued capital of £4,000,000.

Prior to its union with the Central, Randfontein South with its 400 stamps worked independently, and made an average monthly working profit of £44,000, with a yield of 27s. 5d. at a cost of 18s. 3d. per ton, the average working profit per ton being 9s. 2d. It was confidently expected

that with all the benefits likely to accrue in the shape of lower working costs from large scale workings, as a result of the combination the profits per ton would be increased, but, as is invariably the case on the Rand, lower working costs were accompanied by a more than compensating fall in the grade of the ore, with the result that profits per ton declined. Three hundred stamps of the Randfontein big mill were hung up in February of last year, and 105 more in April of this year. For the six months preceding the last entailment the Randfontein has maintained the highest production of any property on the Rand, and was therefore the premier gold producer of the world. Lately there have been rumors that the northern section of the property was not coming up to expectations. No. 8 and Ferguson mines were said to be sending ore to the mill assaying between 3.6 and 3.8 dwt. per ton, and frequently the screen assays at the big mill fell to about 3 dwt. per ton, which, with a working cost of 16s. 8d. per ton could scarcely be considered satisfactory. In the light of these rumors the following comparative results obtained before and after amalgamation will be interesting:

RANDFONTEIN SOUTH BEFORE AMALGAMATION

	Tons milled.	Revenue per ton.	Expenses per ton.	Profits.	Per ton.
1909..	1,121,224	27s. 11d.	18s. 8d.	£519,041	9s. 3d.
1910..	1,168,641	27s. 5d.	18s. 3d.	538,584	9s. 2d.

RANDFONTEIN CENTRAL AFTER AMALGAMATION

1911..	2,159,032	24s. 7d.	16s. 8d.	854,241	7s. 11d.
1912—					
Jan.	215,556	24s. 3d.	17s. 5d.	74,000	6s. 10d.
Feb.	211,443	23s. 6d.	17s. 4d.	65,000	6s. 2d.
Mar.	229,642	22s. 5d.	17s. 10d.	53,000	4s. 7d.

As a direct result of the amalgamation it will be seen that last year the average grade of the ore milled fell from 27s. 5d. to 24s. 7d. per ton, the working costs were reduced at the same time from 18s. 3d. to 16s. 8d., and the profits fell from 9s. 2d. to 7s. 11d. per ton. These figures attracted attention at the time of the issue of the annual report for last year, but owing to the fact that working costs had declined, and the fall of grade and profits per ton milled were only in keeping with the general results attained last year on the Rand, they lost much of their significance. Better results were prophesied for the current year, which had the effect of consoling some of the leading stockholders, but there were others inclined to express misgivings on this point from the lessons taught by the East Rand consolidation.

How these promises have been kept the monthly results for the current year appearing above will show. It is true that in March a record tonnage was milled and treated, but the recovery has fallen from 24s. 7d. per ton for the average in 1911, to 22s. 5d. per ton in March, while costs of working have risen from 16s. 8d. to 17s. 10d. per ton. The result is seen in the decline in profits from 7s. 11d. to 4s. 7d. per ton for March, being exactly one-half the average profits realized per ton by the South Randfontein south section in 1910 before consolidation, of which so much was expected, became an accomplished fact. Regarded in another light, the March results show that by adding in the proportion of a million and a half tons per year from the central section to the tonnage milled from the southern section, this extra tonnage only earned in March a profit of a penny per ton. No wonder need therefore be expressed that the chairman should visit the property and dismiss those responsible for the administration of the mines, the stockholders should become concerned, and the stocks fall in price in what, for other stocks, was a rising market.

Since that date the whole of the administration has been reorganized, but the results are not yet fully known. In April, however, 199,518 tons only were milled and treated, but the recovery per ton milled was increased to that of December last, namely, 24s. 1d. per ton. Whether costs and profits will be restored to last year's figures remains to be seen.

REPUBLIC, WASHINGTON

SHIPMENTS FROM REPUBLIC.—NEW MILL FOR SAN POIL CONSOLIDATED.—POWER DEVELOPMENT ON THE PEND OREILLE.

Shipments of ore from Republic district were lighter than usual during the month of April, amounting to only 3077 tons, as follows: By the Republic Mines Corporation, 2433 tons; San Poil Consolidated company, 360 tons; Knob Hill company, 248 tons; Rathbone Reduction Works, 35 tons. The shipments during May, contrary to expectations, were even less than for April, amounting to only 2547 tons, as follows: from the Republic Corporation, 2077 tons (including 560 tons sent to the North Washington Power & Reduction mill); Knob Hill, 196 tons, and San Poil Con., 274 tons. The decrease in the shipments is probably due to ore being held back for treatment by the local mills.

In the Surprise mine the Republic Mines Corporation is getting out a good average value of ore. Some very good ore is coming from above the 500-ft. level. On the main 500-ft. level drifts are being driven both northerly and southerly on the hanging-wall side of the veins in shipping ore, a stope has been opened which is 8 ft. wide, 50 ft. high, and 80 ft. long, and there is ore still remaining on the foot-wall. Below the 600-ft. level the underhand stope is down 73 ft., in line with the main incline shaft, and produces about 100 tons of ore per week, assaying better than \$50 per ton. From all other parts of the mine from 500 to 600 tons per week are being hoisted through the main incline. The management will probably increase the output 50% for shipment to the smelters. Recently a sample taken from across 7 ft. of the pay-shoot below the 600-ft. level assayed \$404.82, and later a grab sample from the ore-pile broken at that point assayed \$481.90 per ton, of which \$480 was in gold and \$1.90 in silver. The company has over 70 men on the pay-roll.

The Emperor-Quilp company has retimbered the Quilp mine and put it in good shape for breaking ore for the mill. Recently, while breaking ore of milling value on the 200-ft. level, some high-grade ore was found which assayed \$548 in gold and \$98.68 in silver per ton. In the San Poil Consolidated mine the North San Poil No. 2 stope, on the 300-ft. level, has been lately producing ore which assayed from \$15 to \$45 per ton from a shoot believed to be 200 ft. long. The San Poil Con. mill is completed, the machinery is placed, and the plant will begin operation as soon as a railway trestle for the delivery of the ore is finished.

The International Power & Manufacturing Co. has announced its intention of using 10,000 hp. on the Pend Oreille river, and several thousand acres of land in Stevens county will be used in manufacturing lime hydrates, nitric acid, and soil food for the enrichment of lands bordering along the Pend Oreille river. A dam will be constructed about two miles south of the international boundary at a cost of over a million dollars. The outlay of several million dollars in the enterprise is anticipated. Messrs. Ham, Yearsley, and Ryrie, of Spokane, represent the company. Slip clay, good for glazing of pottery, has been discovered in the Orient district.

The Michigan Mining Co. will build a mill on the Gwynn mine, on Hall creek, on the south half of the Colville reservation. A 200-hp. hydro-electric plant, including a compressor, drills, and concentrator, has been purchased. A body of \$35 ore has been found in the shaft, at a depth of 160 ft. It is 6 ft. wide at the bottom. The valuable minerals are chiefly copper and silver.

On account of failure to find sufficient ore of shipping value, the Hope company has closed down the Black Tail mine until arrangements can be made to mill the ore at home. The North Washington Power & Reduction mill has been completed and the machinery is wearing down to its bearings. A large tonnage has been crushed and is under treatment, and assays of the head and tailing indicate a higher extraction than was expected at the start.

General Mining News

ALASKA

FAIRBANKS

Sluicing on Sullivan creek in the Hot Springs district was started about the middle of May. The season was delayed on account of the mild winter and the shortage of snow. Unless heavy rains come as an aid to the situation, the season of 1912 will be short on the creeks in this district.

IDITAROD

The tramway which connects the town with Flat creek is being rebuilt for the transportation of the dredge material which the Guggenheims are shipping in from Dawson. Several miles of new road have also been built on Flat creek in order that the freight may be landed at the point where the dredge is to be set up.

KETCHIKAN

The Mt. Andrew Mining Co. will resume operations about July 1 with a complete crew working two shifts. Development will be confined to finishing the adit on the lower level which was begun for the double purpose of prospecting and drainage. If ore is found, another still lower adit will be driven and the mine worked continuously instead of confining operations to the summer, as is necessary with the present glory-hole system. The company is also planning to recover the 2300 tons of ore which was lost on a sunken barge two years ago. This ore was the richest mined at the Mt. Andrew, with 5.5% copper and some gold and silver. Divers will be brought north and an attempt made to save the ore.

SEWARD PENINSULA

The New Era Mining Co. has been organized in Nome to take over the two small stamp-mills which have operated in that district in past seasons and move them to Snow gulch, where the eight stamps will be assembled in one building for the treatment of a large body of quartz ore, which is reported to carry \$20 per ton.

Six new dredges are expected on the first steamers into Nome, and if it is possible to get them into operation before winter they should add materially to the output of the district. Two of the dredges expected are for the Port Clarence district, two others to be used on Casadepaga creek in the Niukluk region, and the other two are for the Kotzebue country, where they will be placed on the Innachuk river. The prospects for a favorable placer season have been greatly improved by recent heavy rains which have been general all over the peninsula. Sluicing was started in May on winter dumps and dirt hoisted from drifts, but open-cut mining was delayed by anchor ice in the streams.

VALDEZ

A new company to be known as the Alice Mining Co. has been formed, chiefly of Vancouver, British Columbia, capitalists, to operate the Alice property on Shoup bay. The mine will be in charge of M. T. Callaghan, who has ordered machinery, tools, and supplies necessary to begin operations.

ARIZONA

COCHISE COUNTY

The Copper Queen and Calumet & Arizona mining companies have granted all their employees an increase in wages, to go into effect at once. The Copper Queen has posted the following schedule: Underground employees now working 8 hours will be reduced to 7½ hours and will receive the same pay as for 8 hours work, thus increasing the rate per hour. Surface employees now working 8-hour shifts to continue 8 hours. Those now receiving \$2, raised to \$2.15; \$2.25, to \$2.40; \$2.50, to \$2.65; \$2.75, to \$2.95; \$3, to \$3.20; \$3.25, to \$3.50; \$3.50 and over, raised 25c. per shift. Employees now working 9-hour shifts will be reduced to 8-hour shifts and will re-

ceive the same pay as for 9 hours work, thus increasing the rate per hour.

GILA COUNTY

The Superior & Boston Copper Co. is shipping to the Old Dominion smelter, according to a Globe despatch to the El Paso Herald, three cars per week of ore averaging about 8% copper. The ore is coming from the stope below the sixth level on the Great Eastern vein. On the twelfth level the southeast cross-cut is being steadily advanced and is now in the Pinal schist formation. A cross-cut has also been started south toward the Limestone vein, which has been opened through the Limestone shaft to the third level, there being a considerable amount of shipping ore blocked out on the second and third levels. About 55 men are employed.

The Gibson mine, nine miles west of Miami, is shipping three cars of ore per month to the Old Dominion smelter at Globe. The ore is reported to average about 16% copper and is all coming from the fourth level on the Pasquale vein. Drifts are being driven south on the fourth and fifth levels and encouraging results are reported. Ten cars of ore have been shipped since the Gibson Copper Co. resumed the working of the mine in February. About 20 men are employed.

At the Copper Hill shaft of the Arizona Commercial, the drift west on the fourth level has reached the boundary line and connections have been made with a drift from the Gray shaft of the United Globe mine of the Old Dominion company. Work is now being concentrated on enlarging the shaft from two to three compartments, beginning at the fourth level and working upward.

The lease of P. S. Tate and the Lyle brothers on the first level of the Black Warrior mine has expired, and the mine is now being worked by the owner, the Warrior Copper company. Development work is in progress on the fifth or lowest level, where it is reported that good shipping ore is exposed. It is proposed to sink a winze below this level. A small amount of ore is being hoisted and stored in the bins. E. M. White is manager.

Churn-drill hole No. 1 of the South Live Oak Development Co., is still around the 640-ft. mark, no progress having been made for the past two weeks on account of serious caving of the ground and the loss of a string of drilling tools in the hole. The tools have just been recovered and casing will now be put in, and it is expected that drilling will be resumed within the next two or three days. The last 40 ft. of the hole has been in soft altered granite, carrying a considerable amount of copper carbonates, some chalcocite being reported. At the Southwestern Miami, churn-drill hole No. 5 is 680 ft. deep, in schist formation. Hole No. 6 is 545 ft. deep and is in schist. A string of tools is lost in the hole, which is being enlarged with a 10-in. under-reamer preparatory to driving the casing before attempting to recover the tools. Hole No. 7 is in conglomerate and is 305 ft. deep. Hole No. 8 is 100 ft. deep, in schist. None of the holes is yet in ore. One churn-drill is at work drilling hole No. 52 at the Keystone mine. Henry Krumb is making an examination of the mine for the Inspiration Consolidated Copper Company.

The sinking of one of the Inspiration Con. company's new 3-compartment working shafts has been started, and a head-frame and hoisting equipment will soon be erected. The spur from the Arizona Eastern to the millsite and mine has been located. Grading for the concentrator is expected to start in about a month. Three of the development shafts are being sunk to greater depth and the ore is being blocked out for mining. Additional boiler and compressor capacity is being provided at the portal of the main tunnel, after which the underground force will be increased. W. H. Aldridge, representing the controlling interests, is now at the mine.

MOHAVE COUNTY

The annual report of the Tom Reed Gold Mines Co., near Kingman, shows a production of \$798,630.95. Of this amount, \$69,461.76 was added from operations in March 1912, the last month of the fiscal year. Dividends during

the year amounted to 40% on the issued stock, or \$363,822. To the reserve \$25,000 was added.

PIMA COUNTY

The Pioneer smelter at Tucson has been forced to shut down for a few days by a break in the flue-dust chamber. The smelter has been running full blast for two weeks, and the storage-bins were full of ore from recent consignments, so repairs will be rushed and operations resumed as soon as possible. The break was due to the fact that the supports of the dust-chamber were not strong enough to hold up the chamber when full of dust.

PINAL COUNTY

The Douglas Copper Co., which owns 15 claims between Ray and Superior, reports the discovery of a 30-ft. vein in the No. 2 adit. A general assay of the ore showed 14% copper with 12 oz. of silver and 3 oz. of gold per ton. The company has been developing its property for the past two years, and now hopes to be able to sell a controlling interest in its claims to one of the large copper companies. The El Paso & Southwestern railroad has secured a right-of-way through the Douglas property, and the county road to Superior runs through it.

YAVAPAI COUNTY

The Bunker Hill shaft in the Big Bug district has been unwatered and the mining of ore resumed. This shaft is 200 ft. in depth and cuts three ore-shoots with a dip of about 60°. The company intends to mine the richest streak, which is 40 in. wide and averages about \$60, and mill this ore at the Little Jessie plant. The mine is also opened by an adit 2185 ft. long, which is within 50 ft. of a point 350 ft. vertically beneath the shaft. A connection will be made with the shaft for drainage and ventilation.

CALIFORNIA

CONTRA COSTA COUNTY

The officers of the Selby Smelting & Lead Co. have been cited to appear in the Superior Court at Fairfield on June 25 to show cause why they should not be punished for contempt for the alleged violation of the injunction whereby the company is prohibited from so operating its plant as to permit injurious fumes to be emitted therefrom.

The injunction was issued several years ago by L. G. Harrier, presiding judge, when he occupied the bench, but the company has succeeded, by complicated litigation, in preventing it from being enforced.

The matter has been before the State Supreme Court for a long time, but recently that tribunal handed down a decision affirming the judgment of the Superior Court in the granting of the injunction and the opportunity for the contempt proceedings is now open.

PLUMAS COUNTY

Development on the Gruss mine has opened an 11-ft. vein of \$15 ore, in the new shaft now sunk at the lower workings to a depth of 200 ft. The Gruss mine has been noted for small rich pockets, and the discovery of a wide vein is encouraging. It is reported that the company has leased the Sohrero water rights. This will give an opportunity to develop about 160 hp. with turbines working under an 80-ft. head. The 15-stamp mill on the property is being moved to the new shaft, from the old workings 1000 ft. away, and it is expected that stamps will be dropping on rock from the new orebody by the middle of July.

SACRAMENTO

The executive committee of the Anti-Débris Association met at Sacramento on June 15 and received reports from their watchmen who had made inspections of the hydraulic mining property in the state. The Neocene Placer Mining Co. at Seales, Sierra county, which was served with an injunction last month, filed an affidavit that mining would cease after the next clean-up. The Brandy City company, operating near Comptonville, Yuba county, has just been served with an injunction and will probably stop work. This company has been using two giants and attempting to restrain the débris with dams. Complaints have been

made of other companies working on the headwaters of the Yuba river.

SIESTA COUNTY

The Mammoth Mining Co. has purchased the stock pile of eoke at Coram, belonging to the Balaklala company. Approximately 1000 tons of eoke was on hand when the Balaklala closed, and this will now be shipped to the smelter at Kennett.

TUOLUMNE COUNTY

The last clean-up at the Confidence mine was made last week by C. W. Terry. All the ore about the millsite, accumulated from the active operation of the mine, was put through the mill, and several tons of rich concentrate was recovered and shipped for treatment. All the machinery will soon be sold and the mine abandoned. All the ore in sight has been taken from the mine, but the claim contains some unexplored mineralized ground. The Confidence was located in 1853, and is one of the earliest discovered quartz mines in the state. Placer mining was

GENERAL VIEW OF SELBY SMELTER.

demanding the attention of the industry at that time, and only a little work was done on the vein. Some fifteen years later Ben Holliday, the stage owner and pony express man, acquired the property and operated it profitably. Under later owners the mine was worked for years and is credited with an output of over \$4,000,000. At first the concentrate was sent to Wales and a profit of 60% realized on the shipment. Crude methods of treatment were used at the mine, and much money lost in the poor recovery made of the pyrite.

COLORADO

CLEAR CREEK COUNTY

(Special Correspondence.)—The property of the Dives-Pelican and Seven-Thirty M. Co. was sold this week at public sale to satisfy judgments obtained out of the District Court. G. W. Tarkington, who has served as manager of the mines for three years, was the successful bidder, the consideration being \$32,750. The Bard Creek M. Co. is maintaining heavy shipments of both smelting and concentrating ore. The mill ore is being consigned to the Mineral Chief plant. Hammer & Herber, leasing at the Capital mine, are producing from 125 to 150 tons of mill ore each week that is worth \$11 per ton. This ore is sent to the Combination mill at Idaho Springs for treatment. Farragher & Co., leasing on the Gambetta mine on Repub-

lean mountain, started a shipment of 70 tons of lead-zinc ore this week, the product being consigned to the Mineral Chief mill. The Scotia mill is being operated on three 8-hour shifts and lead-zinc-iron concentrates are being shipped.

Georgetown, June 15.

OURAY COUNTY

The Atlas mine, near Ouray, is reported to have discovered a body of high-grade ore.

TELLER COUNTY (CRIPPLE CREEK)

A body of rich ore has been found on the 1500-ft. level of the Vindicator, apparently a continuation of the No. 3 vein south, which produced high-grade ore in the 1400-ft. level. Three ore-shoots have been opened south of the shaft, on the 1500-ft. level and there remain to be found four more, which were mined on the upper level. A change in the drainage system will soon be made at this mine. At present the water is kept at the 1500-ft. level, being lifted from there to the 1400-ft. level, and from there sent into the Golden Cycle shaft, where it is pumped to the surface. A connection has now been made with the Cycle shaft on the 1500-ft. level, and the water will be sent through that level. The production of the Vindicator mine is limited by the capacity of the ore-house, but an attempt will be made to increase the output. The Vindicator No. 2 shaft is maintaining an output of about ten cars per month, shipped by lessees from ore found by following stringers in the old stopes.

The Jolly Tar claim, on Battle mountain, within the corporate limits of the town of Victor, has been sold to Charles Walden, of Victor, who is supposed to represent Colorado Springs capitalists. The price is reported as \$100,000.

NEVADA

ESMERALDA COUNTY

The Florence Goldfield has shipped four carloads of ore from the rich vein recently found by the cross-cut on the 250-ft. level. Development is in progress on the 350-ft. level in search of the downward extension of the same orebody. At the Goldfield Merger mine the shaft is now 1150 ft. deep, but sinking will be carried to a depth of 2000 ft. before any attempt is made at lateral development in the search for ore.

HUMBOLDT COUNTY

The Inlay Mining Co. is overhauling the plant on its property and expects to start milling before July 1. The capacity of the mill is 50 tons per day and over 1000 tons of \$12 ore has been hoisted in readiness for the run. R. H. Siddoway, secretary of the company, reports the discovery of a vein 3 ft. wide, of high-grade ore in the No. 1 level. Assays have run as high as 122 oz. of silver, 65 oz. of gold per ton, with 8.1% lead and 1.3% copper. This vein, which is on the contact between limestone and porphyry, carried only milling ore in the upper levels. It is the intention of the company to drive on the No. 2 level to the vein, unwater the mine, and then raise to this rich ore-shoot.

LINCOLN COUNTY

The railroad from Pioche to the property of the Prince Consolidated M. & S. Co. is completed and ready for operation. The company's locomotive has not yet arrived, but the line may be utilized for transporting ore by the Salt Lake route engines. The company is at present shipping 12 to 15 cars of Bullionville tailing to Tooele daily, and expects soon to be in position to ship from the reserves in the mine of the so-called iron-manganese ore. There is actually developed nearly 900,000 tons of this ore, on which a profit of \$5 is expected.

LYON COUNTY

(Special Correspondence.)—The Yerington Copper Co. is developing an excellent body of copper ore on the 250-ft. level and is sending out occasional shipments. A blower has been installed and development is about to start at the 400-ft. level, where good ore has been found. Arrangements have been made for the building of ore-

bins. D. W. McKenzie and associates have commenced shipments from their Northern Light lease. In the glory-hole a 12-ft. vein is exposed, with about 4 ft. carrying good copper ore. A hoist will be placed and the 150-ft. shaft sunk to the 350-ft. point. It is reported that the Mason Valley company is about to blow in its second furnace, as the first unit is growing inadequate to handle the ore constantly arriving. The solitary furnace is treating 700 tons per day, and producing a matte averaging over 40% copper. The blowers have a capacity of 275 cu. ft. and the blast pressure ranges from 30 to 38 oz. The sulphide ores of the Mason Valley and the carbonates from the Nevada Douglas form an excellent fluxing charge, with only about 5% of lime rock employed. Custom ore is coming in from numerous small gold properties in the district. Converters may be provided before the end of the year. At present the matte is shipped to Garfield, Utah, for conversion into blister copper. The Nevada Douglas reports steadily improving conditions. A raise is under way from the 750 to the 650-ft. level, and from the former a winze is down 30 ft. Three feet of high-grade chalcocite ore is reported exposed. A new adit is being driven below the Douglas Hill tunnel to tap the orebodies at further depth. The company is shipping over 11,000 tons per month to the Mason Valley plant. Considerable attention is also being paid the gypsum deposit, the Western Gypsum Co. recently contracting to take 4000 tons of the product, according to late advices.

Yerington, June 15.

NYE COUNTY

The report of the Tonopah Mining Co. for May shows that 14,948 dry tons were milled, with an average value of \$18.08 per ton. The bullion shipped amounted to 254,700 oz. with a total value of \$206,700. There was also 100 tons of concentrate shipped, valued at \$34,350. The net profit for May was \$141,152. The Tonopah Belmont Development Co. reports a net profit for May of \$125,646.27. There were 7956 dry tons of ore milled, with a net value of 207,405.47. Gold bullion to the amount of 2650 oz. was produced and 261,197 oz. of silver bullion. This is a decrease both in tonnage and net profits from the month of April, due to a break-down of the hoist at the Desert Queen shaft on two occasions and similar trouble with the underground hoist on the 1000-ft. level of the mine. By July 1 it is expected that the new mill will be in operation, and both the tonnage output and the profits should show improvement. Recent development on the thirteenth level has produced good ore. The MacNamara 10-stamp mill treated 2084 tons of ore in May, an increase of over 420 tons from the March and April returns.

The Catherine group of claims at Ione, which were under development by the Midas Gold Mining Co. of Tonopah have been transferred to the Manchester Gold Mining Syndicate of Manchester, England, represented by M. J. Doolin, of San Francisco, who now owns 14 claims in the Ione district.

The Manhattan-Earl property has been bonded to S. H. Brady of Tonopah and John S. Whildin of Philadelphia. Included in the deal is the Priest mill, which has been owned and operated by the Manhattan Milling & Ore Co. It is reported that the new owners will enlarge the mill, equip a cyanide plant, and enter into the competition for custom ore. They will take possession of the mine when the Swanson lease expires August 1, and will enlarge the shaft, preparatory to sinking deeper.

STOREY COUNTY

The Consolidated Virginia Mining Co. has received a net return from the Selby smelter of \$14,066.04 as a result of the recent milling of 520 tons of ore at the Kinkead mill. The concentrate consisted of about 20 tons, with an average value of \$566.82, while the bullion gave a return of \$2337.86. The ore came from the 2400-ft. level of the mine from a recent discovery in the southwest drift.

The Comstock-Phoenix Mining Co., operating on the Brunswick lode, has made a shipment of high-grade ore to the Selby smelter. This company has sent its ore to

the Fischer mill in Sixmile canyon and has shipped concentrate from there for several months, but this is the first car of ore to go direct to the smelter since last fall.

WHITE PINE COUNTY

(Special Correspondence.)—A discovery of platinum has been made on the Ely National, near Illipah in the White Pine mountains thirty miles west of Ely. A shaft was sunk for 127 ft. and a drift run for 60 ft. through heavy black sand, which gave returns from assays ranging from \$2 to \$7 per ton. It is believed that the ore can be mined by steam-shovels and treated by a process of dry magnetic separation into a product worth \$25 per ton.

The Boston Ely Mining Co. has succeeded in lowering a churn-drill to the 1240-ft. level, and will set it up to operate next week. This is the first churn-drill to be used in underground work in this district. For several weeks a diamond-drill has been operated from the same level. A company has been financed which will build a hydro-electric power plant on Cleve creek about 25 miles east of Ely. This plant is expected to cost \$200,000 and will generate 2000 hp. for use in the district.

Ely, June 20.

The Nevada Consolidated has ordered two Shay geared engines to be used in hauling the ore from Copper Pit to McGill. The incline into the steam-shovel pits is now too steep for the locomotives of the Nevada Northern. Some of the engines of the Nevada Northern are being remodeled for the use of oil as fuel. The long haul from California makes this fuel expensive, but it is expected to be more satisfactory than coal.

At the Zaek shaft of the Ely Consolidated, sinking will be resumed in a short time and continued from the present depth of 600 ft. to 800 ft. Development in the lower levels will be carried on, as fast as the shaft is deepened, in search of the continuation of the orebodies found about the 600-ft. level. The new pump in the 600-ft. station is ready for service, and a second 4-in. water column has been placed in the pipe compartment of the shaft. This doubles the facilities for taking care of the water of the mine, and it is believed that there will be no trouble with increased flow.

The California shaft of the Amalgamated Nevada at Blackhorse will be sunk an additional 100 ft. to a depth of 200 ft., and further development commenced at that level. The mill of the company at San Pedro is not running at the present time.

NEW JERSEY

A strike is in progress at the Perth Amboy plant of the American S. & R. Co. and the International S. & R. Co.'s plant at Raritan is expected to be closed shortly by labor troubles. The strikers have been very violent in their demonstrations and have attempted the destruction of the plants by fire. At Perth Amboy the guards fired on a mob of the strikers who were attacking the works, killing one and wounding others.

NEW MEXICO

GRANT COUNTY

Mining operations have been resumed at Santa Rita by the Chino Copper Co. The places vacated by the strikers were easily filled by new men, and work is proceeding as usual. The concentrator at Hurley was kept running constantly from storage reserves.

SIERRA COUNTY

The old placers of the Mesa del Oro, northeast of Hillsboro, are being prospected by J. B. Tully, of San Francisco, who has located 1400 acres. This ground has been worked at random for years and Mr. Tully hopes to prove that dredges can be made profitable.

SOCORRO COUNTY

(Special Correspondence.)—The recent fire that destroyed the ore-bins of the Treasure Mining & Reduction Co. caused only a few days delay in hauling, as new bins were promptly erected. The mill was able to run continu-

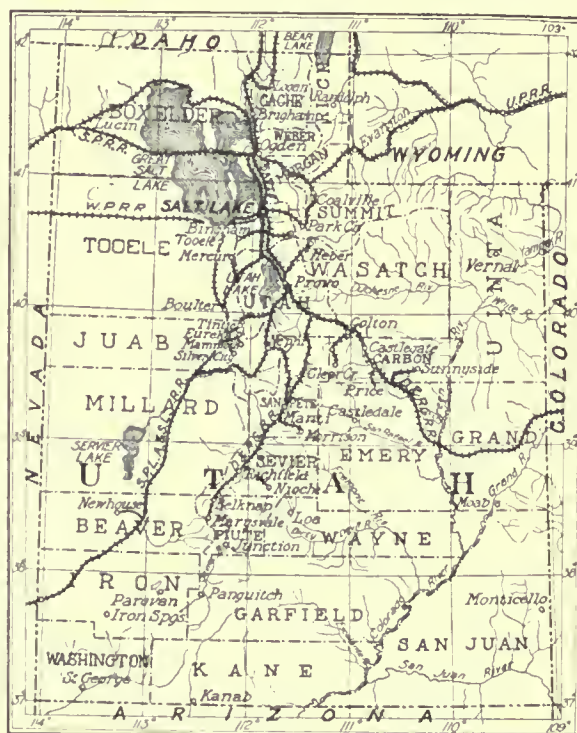

ously, from reserve tonnage, and is treating 70 tons per day. Mogollon, June 14.

Incorporation papers have been filed by the New State Smelting Co., of Socorro, with capitalization of \$25,000. The incorporators and directors are: Frank Dull, statutory agent, Socorro; B. F. Darbyshire, M. C. Edwards, W. H. Case, El Paso.

UTAH

JUAB COUNTY

The Eagle & Blue Bell Mining Co. has been examined by Dunean MacVichie, who reports that ore on the 1300-ft. level has been developed by winzes from the 1000-ft. level, for 300 ft. in length and 70 ft. in width, and the limits of the body has not been found along the strike. The company is driving a cross-cut on the 1500-ft. level to find the continuation of this orebody. High-grade ore on the 700-ft. level has been opened for 38 ft., from 10 to 12 ft. in width. Two cars shipped from this drift netted about \$6000 per car. Mr. MacVichie believes that the orebodies on the

MAP OF UTAH.

700 and the 1300-ft. levels are the same and will be connected by further development.

SALT LAKE COUNTY

The mill of the Columbus Consolidated Mining Co. at Alta has been put into commission, after a thorough overhauling of the plant and the machinery. Enough ore is in sight in the mine to furnish a supply for all summer. A stope on the 400-ft. level, and the S5 stope above this level, are being developed, and the company hopes to add to its orebodies. It is expected that the mill will turn out 20 tons of concentrate per day.

SUMMIT COUNTY

The new tailing dam at Park City, built by the Silver King, Daly Judge, and Daly-West companies has been put to use and is declared a success, as the water leaves the dam clear. The project, which cost \$50,000, has as its object the saving of the tailing from the mines, and the water from Silver creek was diverted on the Richardson flats in order to settle the tailing. The ore shipments from Park City for the month of May were as follows: Silver King Coalition, 2814 tons; Daly-West, 2536 tons; Daly Judge, 2138 tons; Grasselli, 328 tons; Ontario lessees, 64 tons; Frank Daly, 28 tons.

TOOELE COUNTY

The International S. & R. Co. has established a branch office in Spokane, for the avowed purpose of emphasizing

the usefulness of the organization in Coeur d'Alene. Another branch office has been established at Goldfield, Nevada, and F. M. Chambers has been appointed Nevada state agent for the company. The company is in the market for copper, lead, silver, and gold ores, and the competition in smelting fields should work out to the benefit of the ore producer.

WASHINGTON

FERRY COUNTY

Work has been resumed on the North Star & Washington mine, situated on the international boundary line, by the British Columbia Copper Co. In the Laurier mine, near Laurier station, the vein has been found in the adit, about 500 ft. in from the portal and at a vertical depth of about 450 ft. In Covada district the Longstreet Mining & Milling Co. has been organized, and work has been resumed on the Longstreet mine with two shifts. New buildings have been erected for living quarters and mining purposes. The Longstreet vein is 60 ft. wide and has produced shipments of very high-grade ore. The Silver Leaf mine has been bonded for \$25,000, and work will be started immediately. In Keller camp the Walla Walla company has driven an adit about 400 ft. and intersected a vein 33 ft. wide. The ore assays \$15 to \$16 per ton.

The Ben Hur Leasing Co. is breaking ore on two levels, awaiting completion of the mills for its disposal. The Knob Hill company has paid \$45,000 in dividends to date and has a cash surplus with which to pay the balance of the purchase money for the mine as fast as it becomes due. Until recently no ore was broken in the mine that would not stand the cost of mining, transportation, treatment, and a profit at the smelters, but the company has a contract for the daily delivery of 50 tons to the San Poil Con. mill, to begin as soon as the mill is ready to receive it. Of late the company has been shipping 100 tons per week to the smelters. Above the 200-ft. level, stope No. 3 has been opened, and from it a drift is advancing toward a high-grade shoot of ore that was first developed in a shaft near the surface. The No. 3 stope is 30 ft. long and from 20 to 36 in. wide, the ore averaging \$150 per ton. In the shoot is a streak one-half to one and one-half inches wide, estimated to assay \$30,000 to \$40,000 per ton. The smelter returns reported from 10 carloads of ore shipped a week or two ago ran from \$40 to \$99.05 per ton per carload. A new stope of milling ore has been opened above the 400-ft. level.

STEVENS COUNTY

At the Imperial mine the main shaft is being sunk from the 120-ft. level to a depth of 300 ft. At the latter depth cross-cuts will be driven to intercept five separate veins, which traverse the property within a range of 300 ft. at the surface. About \$25,000 has been expended on the property, and as much more is promised this year for development and equipment. Hoisting machinery, compressors, and boilers are now being placed at the mine.

CANADA

ONTARIO

The May production of the Nipissing mine amounted to 374,129 oz., valued at \$226,140. Construction work on the new low-grade mill is proceeding rapidly. The framework on the main buildings has been completed, and a large part of the interior concrete work finished. The 40-stamp mill of the Nova Scotia will be operated again as a customs plant, after a shut-down of several weeks caused by the assignment of the company's assets to its creditors.

YUKON

The Pueblo mine at White Horse resumed shipments of copper ore to Skagway, the last week in April, after being closed for two years. The crew at the mine is loading from three to four cars per day, and later in the summer mining operations are expected to increase this output.

The report of the Yukon Gold Co. for the year ended December 31, 1911, gives the operating profit of the year as \$1,462,042, from which dividends to the amount of \$1,312,-

500 were paid. The officials of the company state that the new placers recently acquired at Iditarod will add greatly to the company's assets. Engineers of the Yukon and Iditarod districts report an early season and estimate an output of gold double the production for the season of 1911. This is partly based on the production for May, which was \$490,300, as compared with \$270,400 in May last year. The average recovery was 81c. per cubic yard dredged, as against 53c. in the same month a year ago.

MEXICO

CHIHUAHUA

All the plants of the American Smelting & Refining Co. in Mexico are running, according to H. R. Wagner, general manager for the company. The smelter in Chihuahua is short-handed, however, and is only able to keep up a force of 350 men. The railway service between the city of Chihuahua and Ciudad Juarez has been crippled, and this also has handicapped the operations of the company. The smelters at Monterey and Aguascalientes are not in the war zone and have had no trouble, while the plant at Velardeña, which is in a troublesome district, has been able to keep a full force of workmen and to maintain a normal output.

SONORA

The Greene Consolidated Copper Co., a subsidiary of Greene-Cananea, has issued its annual report for April. The earnings for the company are given for the last three years as a comparison.

	1911.	1910.	1909.
Total revenue	\$6,045,834	\$5,592,050	\$5,510,846
Operating expense, tax, interest	3,738,703	4,407,301	4,408,287
Net earnings	1,307,131	1,184,750	1,102,559
Depreciation	280,180	864,097	558,542
Net profit	1,026,951	500,653	544,107

The net profit for 1911 was equal to \$1.02 per share. The total production of fine copper from the company's own ores was 37,101,119 lb., and 7,886,151 lb. was produced from ores of the Cananea Consolidated. The total production of the Greene-Cananea was therefore 44,987,270 lb. as compared with 45,680,145 for the preceding year. The total production of silver and gold was 1,295,297 and 5892 oz., respectively. The average price received for the copper was 12.886c. per pound. The cost of this copper was 9.088c. per pound, or 9.84c. including construction. The total cost per ton of ore during the year decreased from \$5.765 to \$5.257, and the extraction in the concentrate was raised to 77.67 from 75% for 1910. The average yield per ton of ore treated was 50 lb. of copper and about 75c. in gold and silver. The assets of the Greene Consolidated on January 1 were \$3,570,484, of which \$2,588,022 was in the form of cash and metals on hand.

The output of the Greene-Cananea smelter for May was approximately 6,750,000 lb. of blister copper, a larger production than the company has ever attained before. This includes, however, not only the copper mined by the company, but also the contents of the concentrate of the Miami Copper Co., which are handled by the Cananea company under contract.

Work on the property of the Nacozari Consolidated Copper Co. has been steadily in progress since last November, when a compressor and machine drills were put in operation. In the past few weeks several bodies of ore have been found. On the Copper King group, which is on the extension of the Pilaes orebody, over 100 ft. of ore was cut through in an adit recently. The adit was run at a shallow depth and the ore was leached to a great extent but samples taken from the ground assayed as high as 11% copper. In the main adit on the Galena group several drifts are being run to cut the veins of lead-silver ore that show on the surface. These drifts have exposed large masses of ore of milling grade, with one to two per cent copper and a few ounces of silver per ton. The company is planning a concentrator for the treatment of these low-grade ores, and expects to have funds for the construction of the mill available during the present month.

Personal

Professional men are invited to send news of their engagements and travels. Such news is interesting to friends.

KARL EILERS is at the Fairmont.

LIONEL BILODEAU has gone to Alaska.

HOWARD D. SMITH has returned from the East.

C. S. HERZIG has returned to London from Nigeria.

H. O. HOFMAN was in San Francisco during the week.

T. N. TURNER sails on the *Nile* today for Nikolaievsk.

PHILIP N. MOORE is expected here the last of this month.

HERBERT HAAS has gone to Arizona on professional business.

F. L. COLE has gone to Korea and Siberia on professional work.

H. D. McCASKEY is in Nevada, visiting quicksilver properties.

CYRIL W. KNIGHT has left Toronto on field work for the summer.

T. KAWAMURA sailed from New York for London, June 15.

J. D. IRVING, who has been ill for several weeks is now convalescing.

ALFRED H. PAGE will be at Vancouver, B. C., for two or three months.

M. K. RODGERS has returned from New York and has gone to Seattle.

H. C. WILMOT is now in charge of the Colorado mine, Philippine Islands.

W. A. PRICHARD has been investigating mining conditions on the Mother Lode.

W. H. STORMS attended the mining congress of Yreka, California, this week.

RALPH ARNOLD was in San Francisco last week and will soon leave for Venezuela.

GEORGE E. FARISH has returned to South Porcupine after a brief visit in New York.

G. W. METCALFE was in San Francisco and has gone to Santa Barbara for a few days.

BERNARD MACDONALD has gone to New York and will be at 35 Wall street for the present.

A. VANDER NAILLEN, JR., is now associated with Heald's engineering school, San Francisco.

EDMUND JUESSEN returned from Sutter Creek and went to Salt Lake City during the week.

NORMAN T. TRACY has been appointed manager at the San José de Gracia, Sinaloa, Mexico.

ROBERT H. RICHARDS was married June 8 to LILLIAN JAMESON, at Jamaica Plain, Massachusetts.

ERNEST R. WOAKES, temporary manager for the Cape Copper Co., has returned from South Africa.

HOWLAND BANCROFT has gone to Utah on professional business, expecting to return to Denver early in July.

N. F. DRAKE has accepted the professorship of geology at the University of Arkansas, which carries with it the state geologistship.

ROSS B. HOFFMANN left St. Petersburg, May 25, for Nikolaievsk, Amur, eastern Siberia, which will be his address for the summer.

F. B. VAN HORN has resigned from the U. S. Geological Survey to accept a position with the Compañia Mexicana de Petroleo El Aguila, S. A.

WALDEMAR LINDGREN is to leave the Geological Survey to become head of the geographical department of the Massachusetts Institute of Technology.

GEORGE I. ADAMS has accepted the professorship of geology and mining in the Pei Yang University, Tientsin, China, and will leave for the Orient during July.

H. L. DAY, former manager of the Hercules, has been made president and general manager for the Federal Mining & Smelting Co. E. R. DAY is now manager of the Hercules.

A. J. McDONALD has resigned as general superintendent of the tale mines and mills of the International Pulp Co. at Gouverneur, New York, which position he has held since the formation of the company nineteen years ago.

Decisions Relating to Mining

Specialty reported for the MINING AND SCIENTIFIC PRESS.

POLLUTION OF STREAMS BY MINING—DAMAGES

In an action against upper riparian mine owners for the pollution of a stream by the waste from their mines which flowed down and injured plaintiff's lands, evidence of general benefits accruing to plaintiff's lands, in common with all the land in the vicinity arising from the fact that operation of defendant's mines caused an increase in the population, was admissible in mitigation of damages. But plaintiffs were entitled to recover damages notwithstanding that the pollution of the stream was a necessary consequence of the operation of the mines, for the necessities of one man's business cannot be made the standard by which to measure another's right.

Arminius Chemical Co. v. Landrum. (Virginia) 73 Southeastern 459. January 18, 1912.

RIGHTS OF WAY OVER FOREST RESERVES IN ALASKA

Section 4 of the Act of Congress of February 1, 1905, which provides that "Rights of way for the construction and maintenance of dams, reservoirs, water plants, ditches, flumes, pipes, tunnels, and canals within and across the forest reserves of the United States are hereby granted to citizens and corporations of the United States for municipal or mining purposes, and for the purposes of the milling and reduction of ores during the period of their beneficial use, under such rules and regulations as may be prescribed by the Secretary of the Interior, and subject to the laws of the state or territory in which the reserves are respectively situated," has been made applicable and operative in the District of Alaska by a decision of the Land Department.

Alaska Treadwell Gold Mining Co. et al., 40 Land Decisions 426. February 12, 1912.

MINERAL SURVEYS—COMPENSATION OF SURVEYS

Under section 2234, Revised Statutes of the United States, authorizing the Surveyor General to appoint surveyors to survey mining claims, and providing that the expenses of the survey shall be paid by the applicants, and authorizing the Commissioner of the General Land Office to establish maximum charges for surveys, and under the rules of the Interior Department, the employment, manner, and amount of payment for the survey of mining claims, are subjects of private contract between an applicant and a deputy surveyor. But, where an applicant and a deputy surveyor have made an arrangement as to payment, the surveyor must make the survey and return correct field notes without delay, notwithstanding any dispute over the payment of fees.

Fish & Hunter Co. v. New England Homestake Mining Co., (South Dakota, 134 Northwestern, February 14, 1912.

NATURAL GAS HELD TO BE A MINERAL

Natural gas is a mineral, and while in place in any particular land it is a part of the land itself. It therefore belongs to the owner of the land in which it is found, and as long as it remains in the particular tract of land, the owner of the surface is the owner of the gas beneath it. It has been uniformly held that conveyances of gas in its natural state in the land require all of the formalities of a conveyance of any other interest in the same real estate, and that the ownership of the gas passes to the grantee of the land itself in event the right to the same is not expressly reserved in the deed conveying the land. It follows that by a conveyance of a tract of land, with no reservation therein the grantee obtains title to all the natural gas that exists in and is captured beneath the surface thereof, although such gas has escaped from the land of an adjoining owner.

Osborn v. Arkansas Territorial Oil & Gas Co., (Arkansas) 146 Southwestern 122. April 8, 1912.

Concentrates

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

HYACINTH is a clear brownish orange, or reddish colored zircon, which is cut as a gem.

POOD is a measure of weight much used in Russia. A pood is equivalent to 526 troy ounces.

KATANGA copper sold in Antwerp is in the form of bars weighing 100 to 400 lb. and analyzing 89 to 90% copper, 4.5 to 5% cobalt, 0.3 to 2% iron, and 0.5% sulphur.

INDUCTION motors of the squirrel-cage type should be selected for use in damp or wet places, due to the more rugged and reliable construction of the motor, making it less liable to insulation troubles.

GOLD was discovered in Russia in 1733 at the Voitsky mine, Government of Archangel, in a quartz vein. Russia is one of the few countries in which placer mining followed rather than preceded quartz mining.

TUNGSTEN is principally used as an alloy for tool steel. An addition of 16 to 20% used in lathe tools will enable them to be speeded up until the chips leaving the tool are at a blue heat; an operation that would ruin the temper of high-carbon steel.

MAXIMUM speed in hoisting is only attained for a short portion of the time that the skip or cage is in travel. At Kimberley, Alfred Williams found by test that when hoisting 2500 ft. in 59 sec., a maximum of 4800 ft. per minute was attained.

CADMIUM is now recovered as a by-product from the treatment of zinc ores in Colorado. It has long been known that cadmium-bearing minerals occurred with the zinc ores of Leadville as at Joplin, but absence of demand for the metal made it unprofitable to attempt its separation. Even now only a small part of the cadmium occurring in American zinc ores is saved. Where it is recovered it is by treatment of flue-dust caught in a bag-house.

EXTRALATERAL rights apply to the dip, not the strike, and a vein therefore which, on its course extends into patented grounds, conveys no rights upon the discoverer, even though his shaft be upon unpatented ground, except as he may follow down the dip within his actual or constructive end lines. State laws do not affect this matter though it is possible for a state by declaring mining a public use, and providing suitable condemnation proceedings, to open the way to the working of mineral under private lands.

Commercial Paragraphs

THE LODWIC CONCENTRATOR CO., of Los Angeles, claims that the statement that the United States District Court of the Southern District of California on March 5, 1912, granted a perpetual injunction against all persons claiming or pretending to have any interest in or rights under the Lampert patents, is incorrect, and that the court did nothing of the kind. The Lodwic company states that the injunction issued in this case enjoined Jacob Lampert and P. B. McCabe, their agents, attorneys, servants, and employees from claiming to have, by virtue of the Lampert patents, any rights in the invention covered by the Wilfley patents. Also that the said court did not declare the said Lampert patents invalid, and that the Lodwic Concentrator Co. is manufacturing a table which is covered by the claims of the Lampert patents.

EDITORIAL

SUNNY JIM emerged from the gloom at Chicago for a few moments last Saturday. We had thought groundhog day came in February.

WYOMING has joined the states asking for a local mining experiment station. Delaware, Florida, and Rhode Island are still to be heard from.

RECORD copper production was attained by the Utah Copper Company with a May output of over 10,000,000 pounds. As a monthly output from ores but a few years ago considered as too low grade to be of value, it is interesting evidence of how quickly our point of view can be changed, and serves to lighten the gloom when statisticians compute the brief period of years required to exhaust the known mineral resources of the United States at the present rate of consumption.

MANY stories have been told of the Japanese prince in the kitchen seeking knowledge, and it may add zest to the reading to note that Viscount Inouye, who describes elsewhere the flotation process used at the Kamioka mine, served his time as an unknown laborer at the Globe smelter. After graduating from the Imperial University at Tokyo and studying some years in Germany, he wisely went to work at the bottom to get practical knowledge. How well he succeeded is instanced by his position as professor of metallurgy in the Imperial University at Kyoto and adviser to numerous important mining corporations.

NO feature of recent development of the mineral industry is more striking than the growing importance of the minor minerals. New uses for them are being found daily and a knowledge of the mineralogy of gold, silver, copper, lead, and zinc no longer suffices the prospector. Ore worth \$400 per ton is worth the hunting, whatever be the mineral that gives it value. On another page Mr. H. C. Morris summarizes the points that will be most helpful to those who turn their attention to tungsten. Other minor metals deserve similar treatment, and an open mind as well as a keen eye is worth while to those who would discover mines.

GUIDE BOOKS are necessary evils, and official documents prop many a faulty memory. No formal report, however, gives quite the same vivid picture of a country as does a personal letter from a friend. He tells you informally the many minor points which you would have noticed promptly, but which so few remember to write. We are glad, therefore, to share with our readers the glimpse of the Rand, with which Mr. Edgar Collins has favored us. It is an attractive picture and sets one to inquiring as to steamer dates and rates. The Rand may have passed its first period of youth and may have become an old story to those who have seen it often, but mighty tasks remain and big problems are being worked out. Who wouldn't be in on the fun? Mr. Collins' story is as interesting as that told by the visiting missionary, who, as is well known, never sounds quite convincing when discussing the hardships of his life, but rouses the greatest enthusiasm when talking of its pleasures.

LOSS of gold in dredging operations was recently demonstrated by a dredge on the Ovens river, Victoria, where it became necessary to turn the dredge around and work back through ground already dredged. In two weeks 45 ounces of gold was recovered, though the yardage handled is not reported. It has been urged that the muddy water produced by dredging the whole face, with the overburden of soil, is responsible for these losses, and that the use of resoiling devices gives returns sufficient to justify their employment on the score of economy alone.

OUTPUT of new securities in 1911 amounted to \$3,956,129,000, according to a French statistician, of which \$1,562,100,000 was floated in North America. The total capital employed in manufacturing enterprises in the United States in 1910 was \$18,428,270,000, according to the census reports. Other enterprises would increase this total enormously, but, even so, the rate of growth is remarkable, and when it is remembered that of the value of the output of industry more than one-half represents the cost of work done upon them, the rapid increase of indebtedness represented by this increase of securities may well offer food for reflection.

PUMP hydraulic sluicing is an important factor in the alluvial gold mining of Victoria, Australia, the number of plants employing this method in 1911 being 34, as compared with 54 bucket dredges. The bucket dredges handled 16,400,000 cubic yards, of an average value of 7½ cents per yard, and paid dividends amounting to \$230,000 during the year. The pump sluices handled 3,000,000 cubic yards, of an average value of 12 cents per cubic yard and paid dividends amounting to \$15,000. This peculiar type of plant was described by Mr. Charles Janin in our issue of November 11, 1911. The total amount of gold recovered by dredging and sluicing in Victoria since 1900 is valued at \$18,000,000.

COMPOUNDING confusion is likely to be the result of the action of the provincial authorities of the new government of China in issuing new silver coins. One of the great handicaps of trade has been the fact that the coins in use in each province differ both in weight and fineness from those employed in the other provinces, producing endless complexities of exchange as well as much inconvenience. The establishment of a republic offered an excellent opportunity for the introduction of a uniform national system of coinage; the matter is one of so much importance in the trade relations of China, and the action of the provincial authorities is so contrary to good public policy that it should be reversed and reprimanded.

AUTHENTIC information about mines is not easily obtained, and in some districts the sway of tradition is strong. The old policy of secrecy is gradually giving way, but from certain companies and in certain districts it is still impossible to get exact data for publication. Keen observers are wont to remark that it is in just such instances that the light of day is usually most needed. Disinclination to share with others professional knowledge by no means always flows from a desire to cover crookedness, but one who is behind the times in this particular is apt to be in others. No man or company is big enough to progress alone, and the best results for all will result from the fullest permissible freedom in exchange of information.

WE publish this week a letter on Alaska development written by Mr. Julius Thompson of Katalla. That we do not altogether endorse his views is but an added reason for giving them space. Mr. Thompson is an experi-

enced mining attorney, well known in Colorado and now resident at Katalla. He presents an important and honest point of view. We have maintained, and are still of the opinion, that whether mineral land be opened by lease or by location and patent, is of less importance than the terms offered in each case. As Mr. Thompson points out, in the Australian states it is common to give the claimant the option of fee or lease, but so universal is the preference for the lease as offered, that one American mining engineer, who had operated there ten years, was at first incredulous when told that a fee could be obtained. Indeed, leasing has become so invariable that in the land office of one of the states, high officials did not know that anything else was possible until the law was pointed out to them a few years ago. Evidently, if the leasing system *per se* is so bad as is urged, the Australians have not known that they have been hurt. Not the general theory, but the actual terms of the law seem to us most important. Above all else, we condemn the paralysis that obtains at Washington. Any system is better than none. There is no possible justification for locking up the territory as a whole, and Congress will fail miserably in its duty if it adjourns without making some provision under which development in Alaska can proceed.

The Fourth and Politics

Thursday next will be the Fourth of July. The eage will hang unused in the shaft, the roar of the stamps will cease, only a thin stream of clear water will trickle down the tailing launder, and only a skeleton crew will attend the furnaces. Everywhere in the United States miners and millmen, so far as possible, will observe the national holiday. For one day at least they will turn away from stopes, stamps, and savings, and think of other things. In many an American village, and in many an American community in far away lands, the day of sports will be broken while some rising young lawyer or some 'wheel-horse of the party' reads the time-honored Declaration. As the fine phrases ring out and the sonorous sentences rise and fall, it would be well to remember that it was not words but deeds that made the Declaration vital. The signers pledged their lives and fortunes, and they and their followers freely expended both.

This is evidently to be a tumultuous year in the United States. Politics will absorb attention as in no year since the Civil War. Balanced phrases and resounding eloquence already fill the air, but acts rather than masticated wind will determine the result. Fundamental differences are to be fought out, and it is well that it should be so. Everyone acquainted with American politics has known for years that the differences within the parties were deeper and more vital than those between them. It has long been necessary in defining a man as a Democrat to say what particular kind of Democrat he was, and the differences between Taft and Roosevelt Republicans are now as great as between followers of Tammany and Bryan. Custom, however, has strong hold, and Americans have gone cheerfully ahead electing men to office who held and represented mixed ideas. There is a time for compromise and a time for no compromise. Progress comes in pulsating movements and radicals and conservatives are equally necessary and useful. No good comes, however, from continuous dodging of an issue; and, looking at the matter in retrospect, it is clear that a more radical revision of the tariff or no revision at all would have been better than the half measure actually passed three years ago. We have had four years of business uncertainty and of general turmoil, and the big reason has been that the President has not given the sort of administration that was expected by the majority of the voters

who elected him. He has attempted compromise in an irrepressible conflict between opposing and enduring forces. True results are not obtained that way, and no good can come from preserving forms after substance is gone. A dead body is only fit for a funeral. Normally the country, tired of progress with one party, might turn to the other, but what peace could Mr. Roosevelt and his followers hope to find in an alliance with Tammany? On the other hand, what comfort could conservatives find in an organization where Mr. Bryan holds the balance of power? Whatever may be our individual convictions as to the rate at which change shall come, and that alone divides radical and conservative, isn't it better to have the issue sharply joined and to fight it out? Business can adjust itself to either basis; provided there really be a definite and predetermined program. There is plenty of room for honest differences of opinion in this campaign, but no place for those who have neither convictions nor courage. For ourselves we have a decided preference for the progressive platform and would rather have the opportunity to vote for it squarely and fairly and risk defeat than to be longer distracted by side issues. The particular occasion for the quarrel, and the personalities concerned, are of minor importance. There is a higher law than that of any national committee, and an appeal to the people is always in order. We hope the issue may be clearly defined and the answer decisive; then all good citizens will cheerfully accept the verdict.

Hindsight, Foresight, and Insight

Hindsight is commonly spoken of with a tinge of contempt, as though it were a common virtue and of but little value, but such an attitude can scarcely be justified, for the possession of real hindsight is at once of great value and all too rare. Ostwald regards the scientific man as the only true prophet; one who from his accurate knowledge of facts is able to project himself into the future and unerringly determine what will be the outcome of a given combination of circumstances. Precise knowledge of available facts is the fundamental prerequisite of the twentieth century augur, and a clear and accurate vision of the events of the past is the reverse of valueless.

What the outcome of a given combination of circumstances will be can be predicted with a high degree of precision by the trained man, but to determine what will be the most probable combination of circumstances is a more complex task, calling for the exercise of foresight. The ore can be milled with determinable recovery at an ascertained cost per ton, but how much ore there is available, and whether it will change in character as depth is gained, is a projection of present knowledge into the future; an extension of hindsight into foresight that in its highest degree is rare and wins appropriate rewards. From time to time there is much discussion of the reasons why the trained engineer is too seldom found at the managerial desk and on the board of directors. The prolixity of the discussion evidences the complexity of the topic, but it is none the less clear than an important reason is that, popular impressions to the contrary notwithstanding, the engineer's mental equipment is too largely composed of insight and hindsight and too little of foresight. It has been cynically said that the engineer is at a considerable disadvantage compared with the physician and surgeon, since the mistakes of the latter are quietly buried, while those of the engineer are permanently in view and remain to confound him and cripple his reputation. Not improbably this reacts to produce an attitude of too great caution in the engineer. It is unquestionable, too, that the foresight of the engineer is subjected to more caustic tests than that of his business associates. If a business man starts a commer-

cial enterprise and the hoped-for railroad is never built, or changed conditions of living demand a different type of product from that he is prepared to supply, he is regarded as unfortunate but not necessarily inefficient. But if the deep shaft fails to intersect the orebody indicated by the surface development, or if the dam breaks in a flood greater than there was any reason to expect, the engineer in charge cannot hope to escape some, perhaps even a considerable amount, of criticism and condemnation. It is unquestionable that some engineers have never attained more than a limited degree of success largely because they were so unfortunate as to be early associated with one or more enterprises that proved failures, while other engineers have been borne to the top upon the crest of the wave of success by the enterprises with which they have been associated. Then, too, to rub elbows with success indubitably is an aid to successful achievement, while a continual outlook of gloom lowers the mental vitality. On the whole, however, great achievement has been the result of accurate and complete knowledge upon which men of foresight have dared to risk much.

Apples had dropped from trees for ages before Newton saw one fall, and saw it for the first time with insight. The significance of the simple relations between common phenomena is less obvious today than when little was known of the laws of nature, for complexity of outlook produces vagueness of vision. The farmer who sees two or three teams pass his place each day can describe them with almost photographic accuracy, while the city-dweller, at the end of his ride downtown in the morning, can describe but little of what has passed before his eyes, and that inaccurately. The man of insight is he who can eliminate the insignificant from his field of vision and concentrate his mental vigor upon the significant. Fortunate is the possessor of insight, for he shall be greatly rewarded.

Rich Ore and Litigation

National, Nevada, came into sudden prominence about two years ago by reason of the discovery of extremely rich ore. Just how rich has recently been shown by the statement of the manager, on the witness-stand, that ore worth \$94,000 was taken from a space four inches wide, three feet long, and seven feet high. Another witness referred to ore worth \$8000 per ton as 'low grade.' As seems to be inevitable in Western America, the discovery of this ore has resulted in a bitter law-suit to determine whether the National Mines Company or the Charleston Hill National Mining Syndicate is the proper owner. The case is now being tried at Carson City, and Nevada's capital, as a result, is more crowded than Anamosa, Iowa, when the Jones county calf case was up for trial. Among those present are Messrs. H. V. Winchell, H. L. Hollis, Walter Wiley, A. N. Winchell, W. A. Wilson, Albert Burch, and A. C. Lawson. With such an array of experts, the case, as a local paper states, "promises to be long drawn out and is very complex," involving such questions as earth movements, alterations, faults, dips, spurs, angles, uplifts, depressions, stages of mineralization, genesis of ore deposits, stratigraphy, structure, petrography, refractory elements, basalts, andesites, dikes, fine-grained rocks, planes, cleavages, tales, the tracing of faults, the bearing of same as it pertains to possessory rights at National, epidotes, first and second deposition, molecular replacement, quartz crystals, filling of cavities, older and newer fissures and formations, how made and the causal actions therewith, with their important bearings as it pertains to the different viewpoints of the parties in interest." If the case is as abstruse as all that, and the ore as rich, there would seem to be need even for the talent assembled.

First Impressions of the Rand

By EDGAR A. COLLINS

It is fitting that the first impressions of the newcomer to this, the greatest gold mining district that the world has ever seen (and the records of recent years make it impossible to dispute the title), should be those of amazement at the colossal extent of the mining industry. From the moment when the Cape Town train first begins to skirt the western portion of the 'reef,' with its 25 miles of continuous mining activity, one cannot fail to be impressed with the magnitude of operations. The succeeding days of sight-seeing in the vicinity of the mines only add to this feeling of 'admiration mingled with awe,' for the innumerable producing mines form as great a contrast to the ordinary Western mining 'camp,' with its half dozen producing mines, as the city of Johannesburg, with its 200,000 people, does to a camp itself.

Consider for a moment a practically unbroken line of mines for a length of roughly 50 miles, and you begin to realize why it is that the Rand 'baket' produces over one-third of the total gold production of the world.* Yet it is the magnitude of operations, rather than the number of mines or extent of the district, which finally impresses the visitor most. Elsewhere a gold mine handling 10,000 tons of ore per month is considered a large property and attracts a good deal of attention in the surrounding country. Should the owners be fortunate enough to have ore developed for two or three years' work ahead, the property gains additional notice and becomes locally famous. On the Rand, however, such a mine is so overshadowed by the bigger properties, with their practically assured tonnages for many years, that they are seldom mentioned except by the employees or those more or less directly connected. One may see by the monthly statistics that such and such a mine is maintaining its output, but it creates no further attention. And when the mine reaches a time when the probable ore reserves are less than four or five years, it is spoken of with a kindly but pathetic indifference, as of an old acquaintance already dead and buried.

It is natural that this should be so to a great extent, because the unique conditions make it possible to gauge the life of a mine with far greater accuracy than elsewhere. With the comparative regularity of the profitable ore, and the vertical bounding planes of the property, the available volume of ore can be calculated with reasonable certainty. But the point of view is also influenced very considerably by the scale of operations in surrounding properties. Instead of being one of a dozen or less the mine under consideration is an insignificant one among many.†

The city of Johannesburg is well built and has some 200,000 inhabitants (of whom some 140,000 are whites), with numerous fine buildings, offices, banks, theatres, a fine hospital, court-house, and other government buildings, together with the nucleus of a university. The streets are wide and well kept, and in the residential district a great number of trees have been planted, and there are many fine houses and gardens. The most characteristic sights in the streets, which distinguish it from other cities of its size, are the native messenger and police 'boys,' and picturesque rickshaw pullers, with their painted legs and head-dress of feath-

ers and ox horns; and the numberless automobiles which rush to and fro incessantly. Without doubt there are more motor cars in Johannesburg than in any other city of equal size. These are used primarily for business purposes—and the reason is obvious when one remembers the distances to the more remote mines.

The climate of the Rand is, on the whole, mild and pleasant. Extreme heat and cold are almost unknown, and were it not for the dust and windstorms the climate would be almost ideal. Away from the mines there is no unusual dust, except during the months of August, September, and October, when the veldt is very dry before the rains commence. But in the vicinity of the mines and enormous tailing or sand residue dumps which deface the landscape there is more or less—and usually more—dust during the greater part of the year. Generally speaking, the winter months of April to July, inclusive, are the most enjoyable. The country is then no longer green, but there is little or no wind and the days are sunny and bright, with clear cool nights.

During the summer months, December to February, inclusive, rains are frequent, accompanied by heavy thunder and lightning storms. At such times the rain pours down with tropical violence, and within a few minutes every hollow is filled with water.

It is popularly imagined by Europeans and others having no personal knowledge that the climate of the Rand is unsuited to physical labor for white people. Such is far from being the case. As a matter of fact, it is superior to that of many English-speaking countries. Moreover, even underground, in the deep-level mines, the temperature is lower than it is in many of the Nevada mines.‡ The real reason which makes it undesirable for the white man to engage in the heavier tasks of manual labor underground is purely one of race difference. Whether true or otherwise, it is generally believed that the white man will be lower in the opinion of the native if seen performing acts of physical labor. No doubt there is a certain amount of truth in this assertion, but the result has naturally tended to lower the efficiency of the white man. As is well known, there is a shortage of labor in the mines. The number recruited each year has increased until the total number employed is now about 200,000 'boys,' but the work at the mines has increased to the same, or an even greater extent, and the shortage continues and tends to increase in spite of the ever increasing use of rock-drills. At the same time the need of white men has increased in almost the same proportion, and at the present time the demand for good miners far exceeds the supply. Inexperienced workmen and beginners, locally called 'learners,' have filled the vacancies, but really skilful miners are rather scarce and in great demand. Such men can always secure good contracts and can easily earn £40 to £60 (\$200 to \$300) per month. The average white man, however, is not particularly skilful, and is, on the whole, inferior to the average Western American miner in both skill and energy. To some extent this is due to the ravages of that scourge of the Rand, miners' phthisis or silicosis, which has incapacitated or removed the elderly miner, who would otherwise leaven the majority and teach the younger generation. It cannot be ignored that this terrible disease has been responsible for a large mortality—among the white miners, at any rate—and while the preventive measures now in force in practically all of the mines will undoubtedly prove beneficial, some years must necessarily elapse before the improved results will be apparent, because of the large number of men already infected. The younger generation will undoubtedly reap the benefit, and as they will be the

*The production for the Rand for the year 1911 was 7,896,802 oz. of fine gold, approximate value \$162,220,000, while the world's production of gold was valued at \$454,874,014.

†During the month of May 1911, for instance, the following list of 16 mines milled more than 40,000 tons of ore, and of these the first three averaged over 160,000 tons each:

- | | |
|---------------------------|-------------------------|
| 1. Randfontein South. | 9. Langlaagte Estate. |
| 2. East Rand Proprietary. | 10. Robinson. |
| 3. Crown Mines, Ltd. | 11. Robinson Deep. |
| 4. Simmer & Jack. | 12. New Modderfontein. |
| 5. Geldenhuis Deep. | 13. Simmer Deep. |
| 6. Knights Deep. | 14. Witwatersrand Deep. |
| 7. Nourse Mines. | 15. Village Deep. |
| 8. Rose Deep. | 16. Village Main Reef. |

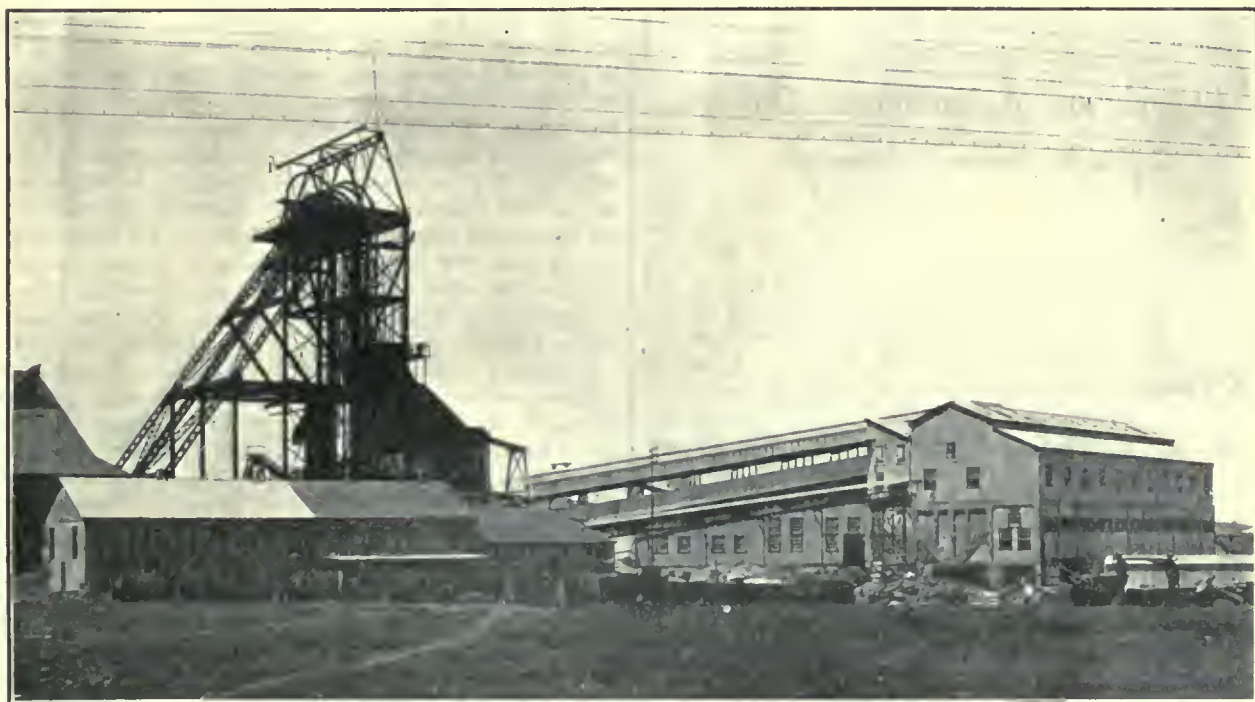

‡The natural increase in temperature due to increase in depth is unusually low on the Rand. Roughly, the increase is 1° F. for every 200 ft. in depth, as compared with 1° for every 80 ft. in the mines of Tonopah, Nevada.

miners of the future this is a most important feature.

To the newcomer—unless he has had extensive experience on a large scale in Mexico or South America—the native labor cannot help but prove a matter for grave consideration, and incidentally for surprise and interest. At many of the deep-level mines the daily underground crew consists of some 1500 to 2000 'boys,' as the natives are called. The problem of handling such a large number expeditiously, from the compound to the working points and back again, is no light matter. Many of the main working levels are over 2000 ft. deep, and even with two and three-deck cages, hoisted at high speed, it takes hours to hoist and lower the shifts. Allowing 12 'boys' on each deck, and with three-deck cages making the round trip in 6 minutes (which is quick work), it is only possible to hoist about 700 'boys' per hour, with a single winding engine. Consequently, if the full quota were to be hoisted from one shaft it would require two hoisting engines to complete the work in about

opportunity and individual preference, and forms such a large proportion of those engaged in the profession in the United States, and to a lesser degree in England and other countries, is conspicuous by his absence. The explanation is simple. Owing to its unique occurrence and origin the 'bantek' formation of the Rand does not offer the numerous promising prospects and small mines which appeal to the small operator commanding a limited capital. In addition, the fact that 75% of the mines are controlled by three or four financial groups, limits and centralizes the field of the consulting engineer.

The position of the mine manager on the Rand is also noticeably different from that of the same official in other parts of the world. Under the law he is held responsible for the carrying out of the requirements of complicated and detailed legislation. The Mining Regulations are framed by a fatherly government, and, in the main, are doubtless necessary from a humane point of view. Their observance,

THE CITY DEEP SHAFT, JOHANNESBURG.

1½ hours. As a general rule, however, there is more than one shaft available, and portions of the two shifts are handled at the same time. In this way the total time occupied in handling the shifts will probably average about 4 hours per day. In order to avoid delays and accidents from overcrowding, native police boys assist the top-man and cage-tender in supervising the loading and unloading of the cages. In some mines which are not yet producing heavily a single cage and skip is used. In this case boys are allowed to ride in both cage and skip.

Time is of little moment to the native, who will cheerfully wait for hours at the shaft station, dozing, while waiting for his white 'boss' to come down, or to be hoisted to surface. Frequently the hand-drillers (hammer boys) are allowed to go to surface as soon as they have completed an allotted task, in order to encourage them to work hard. For, although the native does not mind waiting around underground, he much prefers to do it on the surface, in the sunshine. It should be mentioned that these hammer boys are paid according to the number of inches drilled (with a minimum task), so that they gain directly in proportion to their exertions.

The status of the professional mining engineer on the Rand is unusual. He holds one of two positions. Either he is engaged as consulting engineer for one or more mines, or he is employed as a manager on one of the mines. In either case he is usually in the service of one of the large financial houses. The independent consulting engineer who undertakes inspections or mine management, according to

however, is a source of endless worry to a conscientious manager, who can never tell when the neglect of a subordinate, and the action of an over-zealous deputy inspector of mines, will result in a summons to appear before the local magistrate, with the more than possible chance of a heavy fine. In addition, the manager has, in the majority of cases, the never failing demand for increased production to spur him in his efforts, with the knowledge that if he is successful in keeping his reduction plant operating at full capacity—additional plant will probably be erected. These are of course part of the ordinary work and trouble of a mine manager in any country, where native labor is employed, with the additional effect of *intensified production*.

On the other hand, however, the manager on the Rand has very little voice in the policy or in the general plans which are formulated. New construction is approved by the Board of Directors and the work may be carried out, against his advice and recommendations. These matters are settled by the directors, acting with the advice of the consulting engineer, as is usual elsewhere, but without the advice of the manager, which is usually called for in other countries. There is a certain justification for this arrangement, for with such enormous properties it is rightly considered that the details of management are enough to occupy all of a manager's time. But where, as is sometimes the case, a consulting engineer is over optimistic, and promises more than the mine will properly produce, or where the consulting engineer is changed (a not infrequent occurrence) the unfortunate manager is not to be

envied. He is called upon to produce more than the mine can efficiently output, and is too often forced to mill unprofitable ore, or else to neglect development, and allow the mine to suffer.

It is not within the province of an article of this kind to attempt to suggest remedies, or to discuss the pros and cons of the matter. I have simply mentioned a few of the troubles which impressed me as to the position of the mining engineer, and more particularly to those acting as mine managers on the Rand. To a lesser degree these same troubles are felt by the subordinate officials around a mine, but naturally they have less responsibility. However, there seems far too much shifting around among the various officials, and efficiency naturally suffers. It cannot be otherwise, when there is a general feeling of uncertainty among the employees of a property, from manager down to 'mucker.' It is only fair to add that the evil results of such a condition as outlined are fully recognized by many of the most influential representatives of the different mining groups, but the problem is a difficult and complicated one, and it cannot be solved in a day.

Cyanidation of Antimonial Tailing

By W. ARCHER LONGBOTTOM

*The treatment of the refractory tailing produced from the mines of the Hillgrove district, N. S. W., has had the attention of metallurgists from time to time, but till lately the results were not satisfactory. The chief cause of the trouble is the antimony, which is present in varying quantities in all the mines. Even after careful concentration the tailing carries quite an appreciable amount. Antimony being present as stibnite (Sb_2S_3), it would be natural to expect a large consumption of cyanide, but work in the field has shown this is not necessarily the case. The cyanide used is never abnormal, even when dealing with the most antimonial tailing. The ore, as a matter of fact, is fairly high in cyanicides; stibnite, a little copper, and pyrite being present besides the gangue.

The chief difficulty is the extraction and the production of gold of good quality from the zinc precipitate. The stibnite is decomposed and the antimony gives trouble throughout the operation. It is an interesting problem to determine the actual manner in which the gold is contained in the tailing. After many experiments I have come to the conclusion that it is not in a free state. With the finest grinding, and studied under the most powerful glass, no free gold could be detected. The question then naturally arises as to how the stibnite and the gold are associated; whether the latter is contained by the former as infinitely small particles, or—and this seems more probable—whether the gold is thinly coated with the stibnite so as to prevent amalgamation. That the stibnite always contains gold can easily be proved. Assays of practically pure sulphide, even in a crystallized form, will show 8 dwt., or occasionally $\frac{1}{2}$ oz. per ton.

The problem resolves itself into attacking and disintegrating the sulphide of antimony, and the freeing of the contained gold for cyanidation. The possibility that at least some of the gold is intimately associated with the stibnite is confirmed by the fact that there appears to be a limit to the value of the residue, and even the most protracted treatment will not lower it appreciably. The metallurgist must start, therefore, with the assumption that complete metallurgical success is practically out of the question, though a fair commercial one can be obtained. All the mines in operation on the Hillgrove field have cyanide plants working, and in addition the tailing from the Eleanora Mines, stacked in the early days, have already been treated by cyanidation—some of them twice—and are being put through again by W. H. C. Lovely, an Australian metallurgist with South African experience.

At this plant the tailing has been exposed to the atmosphere for many years, and is strongly acid. There is some difference of opinion among the local chemists as to whether

tailing fresh from the battery is easier to treat than that which has been stacked long enough to permit oxidation. I believe that though the extraction may be a little lower on the raw tailing, the consumption of cyanide is much greater for an equal extraction of the old sand; also the zinc precipitate does not yield the same quality of gold as from fresh tailing. There are 18 treatment vats in use, each 20 by 4 ft., with a capacity of 30 tons. They are arranged in pairs, with a tram line running the full length of the series. They are fitted with the ordinary false bottom of slabs nailed together to conform with the circular section, and covered with hessian cloth, or, better still, cocoanut matting. Each tank has a 2-in. delivery pipe, and may be drained at will into the one common pipe leading to the gold sumps.

The sump capacity consists of six 30-ton tanks, and as quick and convenient means of pumping is provided, this sump room is ample. There are three gold tanks, each of 15 tons capacity, connected with siphons, and can be used separately at will. The precipitation boxes are six in number, and are 20 ft. long by 18 in. square. Pumping is done by 2-in. centrifugal pumps, so arranged that the material can be pumped into any sump required. There are two smelting furnaces for the clean-up, side by side, each capable of taking four '30' and two '90' plumbago crucibles, which are lifted in and out by means of an elevated lever, and are protected by clay liners. The zinc precipitate is treated with acid in six wooden tubs, 3 ft. in circumference, and there are besides six smaller vats. An ordinary flat sheet of thin iron is used for drying purposes, and, contrary to usual practice, the edges of this plate are not turned up. Power is supplied by a large Cornish boiler. The fuel used is ordinary billet wood, and about $1\frac{1}{2}$ cords is burned weekly.

Method of Working.—The dump has been worked on the open-cut system, starting at the middle and working toward the edges, the sand being brought up by means of an inclined tramway. At the surface level the cars are emptied by contract into the treatment vats. The residue is disposed of also by contract. The time of treatment is seven days, including time of emptying and filling, and altogether seven washes of different strengths are run on; the strong solution first, then the weak wash, and finally a quick water wash.

The tailing has been exposed to the atmosphere for many years, the metallic sulphides have given rise to the formation of acids, and this acidity—free and latent—must be dealt with. On the whole, neutral solution, or a very slight protective alkali, is aimed at to give the most successful results. I have experimented with acid solutions, making use of the nascent hydrocyanic acid for the dissolving of the gold, and, by the addition of caustic soda, giving rise to the regeneration of free cyanide according to the equation $\text{HCN} + \text{NaOH} = \text{NaCN} + \text{H}_2\text{O}$, but the method appears to have two disadvantages: (1) the consumption of cyanide is liable to be larger with acid solutions; (2) the presence of caustic soda is troublesome, and fouls the precipitation boxes. The importance of the alkalinity or acidity of the solutions cannot be overestimated when dealing with antimonial tailing. If the protective alkali is in any excess, antimony sulphide is taken into solution and deposited on the zinc as metallic antimony, which generally means trouble in smelting.

The acidity of the tailing at Mr. Lovely's plant is neutralized by lime. This is added in calculated quantities as the treatment vat is being filled, and all precautions are taken against the solution of the antimony, at the same time allowing the sulphide to release the gold. The amount of solution made up and pumped daily on the vats is 100 tons. The solution from the treatment vats is drained away into gold sumps, and from them flows to the zinc-boxes and is passed through the precipitating room in the ordinary way, and the precipitate solution is once more made up to required cyanide strength and used again. The solution is occasionally purified by the addition of some powerful oxidizing agent, as permanganate. Lead acetate is sometimes used to accelerate precipitation, and also to throw down any sulphides there may be in solution.

The Clean Up.—At regular periods the zinc-boxes are

*From *The Mining and Engineering Review*.

cleaned up. The method does not differ materially from usual practice, and a few words will suffice. Only the short zinc is treated, the long zinc being replaced in the top compartments, while the lower ones are filled with new zinc. The slime is allowed to settle all night under the sulphuric acid, to make sure that all the short particles of metallic zinc has been dissolved. The supernatant liquor is then siphoned off and the heavy black slime dried over a wood fire. This slime when dried will usually average in value about $1\frac{1}{2}$ to 2 oz. per pound. They are then suitably fluxed—soda, borax, silica, and flourspar being used—and smelted. Mr. Lovely departs somewhat from general practice, inasmuch as he obtains the gold in the form of base bullion, by the addition of lead oxide to the charge, reducing it by inserting rods of metallic iron in the charge. The bullion is then cupelled in specially prepared cupels, each one of a capacity of about 40 oz. This method has the advantage of giving remarkably clean ingots.

Mr. Lovely gives the following as approximate costs of treatment:

	Per ton,
	s. d.
Labor (total)	2 0
Cyanide	0 8
Zinc	0 $1\frac{1}{2}$
Fuel	0 2
Chemicals, etc.	0 $1\frac{1}{2}$
Royalty	1 0
Total	4 1

These costs are low, the cyanide item being particularly surprising considering the class of material being treated. All labor is on the contract system, and is quite satisfactory.

Prospecting for Tungsten

By H. C. MORRIS

Tungsten ores are found in most of the Western mining states, as well as in a few of the Southern and New England states, and usually occur in 'pockety' deposits in quartz and calcite, or as veins cutting siliceous, igneous rocks, such as granite, granitic schist, or gneiss. There are exceptions to this, and it is never wise to neglect to test a suspected mineral simply because it happens to be found in a seemingly improbable country rock. The same veins often carry one or more of the precious or base metals. Tungsten minerals almost invariably accompany deposits of cassiterite (tin stone), as in Lawrence county, South Dakota, where the tin and tungsten are found in pegmatite. Tungsten-bearing veins have also been found in limestone near igneous intrusions.

The principal commercial deposits in this country are, first, those of Boulder county, Colorado, which produced two-thirds of the total ore and concentrate mined and shipped in 1910. This is probably the most productive district in the world. The ore is ferberite and occurs in small veins and stringers with quartz in granite and gneiss. Apparently related veins nearby carry gold, silver, vanadium, molybdenum, and tellurium. Some of the mines in this district are three or four hundred feet deep with no apparent decrease in the value or quantity of the ore.

The next largest field is the Atolia district in San Bernardino county, California, where the ore is scheelite. These deposits are not only the largest of the kind in the United States, but the largest known scheelite deposits in the world. The ore occurs in quartz and calcite veins in an acid granodiorite and extends through an area of schists to the northwest, where the narrow quartz veins carry both scheelite and gold. In the Papoose, formerly the richest mine in the district, the ore was almost white scheelite which resembled coarsely crystalline limestone.

Cochise county, Arizona, produces some ore, principally hübnerite, from quartz veins in a coarse granite, but the largest production has come from placers. Comparatively small quantities of ore have also been shipped from Stevens county, Washington; from Nye, Humboldt, and White

Pine counties, Nevada; and from several other places.

There are four commercial tungsten minerals, of which the first three are so closely associated that they grade into one another and are not easy to distinguish. They are hübnerite, a tungstate of manganese; wolframite, a tungstate of manganese and iron; and ferberite, an iron tungstate. These three minerals are about three-fourths—or 76%—tungstic acid, of which the chemical symbol is WO_3 . Scheelite, the fourth mineral, is a tungstate of lime which carries more than 80% of the valuable tungstic acid.

As before stated, hübnerite, wolframite, and ferberite—particularly the first two—are so often found together and are so similar that one description will suffice for them all. The color varies from gray in hübnerite to brownish black in ferberite, and the streak or color of the powder when the mineral is scratched, ranges from light yellow to dark brown. Hübnerite is generally translucent, but wolframite transmits very little light and is nearly black, while ferberite is black, transmits no light, and often forms in crystals with chisel-shaped ends. A specimen of any of these three minerals would be about three times as heavy as a piece of quartz of equal size, twice as heavy as zinc-blende, or black-jack, and half again as heavy as magnetic iron ore. Hübnerite can be scratched with the point of a knife, but wolframite is less easy to scratch, and ferberite is still harder.

Scheelite varies in color from a rather glassy white to yellowish or reddish, and sometimes has a slightly greenish tinge. The crystals are shaped like square pyramids, and are sometimes almost transparent. Scheelite has a white streak and is easily scratched with a knife, and is more than twice as heavy as quartz, although lighter than the other tungsten minerals. Scheelite might be mistaken for feldspar, although the latter is harder and is only about half the weight of the tungstate. It is also sometimes mistaken for barite (heavy spar), but is very much harder and much heavier. All four of these minerals are most often found massive, or without easily recognizable crystallization.

The chemical testing of the tungstates is so simple that it is not worth while spending too much time endeavoring to determine them with the eye or mechanically. The only equipment needed is a little hydrochloric acid and a few pieces of zinc, or anything containing tin, such as a tin can, tinfoil, or even solder. It will add considerably to the convenience of testing if a few test-tubes are available, and an alcohol lamp made from a small medicine bottle with some twisted cotton string for a wick will facilitate heating. If these aids are not available, a china cup or drinking glass and the campfire will do.

To test scheelite, a piece the size of a pea should be powdered and put in the test-tube or glass with about a teaspoonful of hydrochloric acid and boiled until a bright yellow powder is formed, which is an oxide of tungsten. After allowing the liquid to stand for several minutes, add a bit of zinc or tin can, tinfoil, or solder as large as a dime. The liquid will then turn blue, changing to wine color, and finally become brown, but the entire change may take several hours.

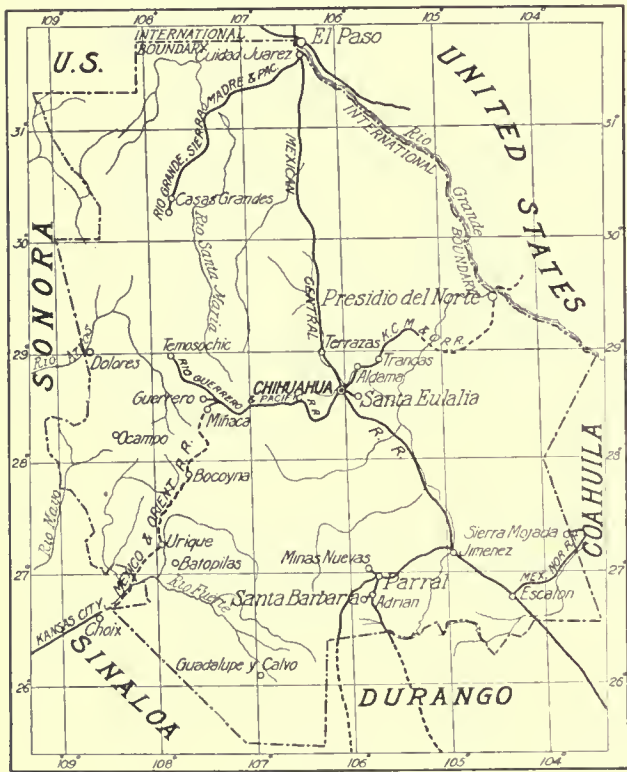

The other minerals should be tested in the same way, but the boiling should last fifteen or twenty minutes. No yellow powder will show, but the blue to brown color will appear on the addition of zinc or tin.

Tungsten ores are milled in stamp-mills, concentrated on tables, the coarse tailing reground in tube-mills, and finished on vanners and canvas. The ore, or concentrate, is paid for according to the percentage of WO_3 at so much per unit (1% of a ton, or 20 lb.). The higher the percentage of WO_3 , the greater the price paid per unit. Standard quotations are for ore running 60% WO_3 or over, and the price at present is \$7 and \$8 per unit, which would make a 60% ore worth between \$400 and \$500 per ton. Any of the large assay offices will make a quantitative determination of the exact percentage of tungstic acid in samples for about \$3 to \$4, depending on the form of combination of the mineral, and will advise regarding the best market for such ores.

Mining in the Morelos District

By G. L. SHELDON

The Morelos district is situated in the southwest part of the state of Chihuahua, just south of the Batopilas district, and north of the Guadalupe y Calvo district. It is reached from the east over the Kansas City, Mexico & Orient railway, to within about 25 hours muleback ride north of Batopilas, Morelos being over 40 miles south of there. From Parral it is 60 miles over the railroad built for lumber and timbers, to the terminus, Zandia, and thence six or seven days muleback. The best route is from the west side, leaving the railroad at Fuerte, a journey of 35 to 36 hours, in the saddle. The town of Morelos is on Morelos creek, about two miles above where it empties into the Tenerivia river, which about eight miles below joins the San Miguel, the most eastern and southern headwaters of the Fuerte river. The town lies at an altitude of 2500 ft. and is a very old one, and in the early days the govern-

MAP OF CHIHUAHUA.

ment had a mint there, coining silver slugs of 10, 20, and 50 ounces.

About 1½ miles northeast of the town is the San Pedro-Anastacio mine, and near by is the San Gil. The former has a record of nearly \$2,500,000 (I have seen the records), and in 1867 one of J. B. Haggins' men offered \$1,500,000 for it. The orebody is in diorite; when the vein passes into the granite it carries no valuable minerals. The formation and general physical conditions are the same as the famed Batopilas mine where much native silver occurs.

This mine was worked continuously from 1840 to some time in the eighties, when the old owner, who was an enterprising and practical mining man, died. His sons soon let it fill up with surface water and lost it. It has not been worked since until recently, when some Americans bonded it from the present owner, Manuel Perez, who is now the mining agent of the district and has been for the past twenty years. He was educated in California and is a competent honorable man. The Americans are extending a long cross-cut, which was driven in about 300 ft. This cut the vein and was driven some distance on it, but being in granite it carries nothing; it will cut the old workings at 300-ft. depth, in the diorite. The ore is free-milling and

was treated by the patio process, being ground in water-power arrastres.

The San Gil, which in recent years has been owned by Henrique Creel, formerly Ambassador to the United States, has the same physical conditions as the San Pedro-Anastacio. It lies higher on the mountain and is developed by adits. It has been worked largely by lessees, more recently by Conness Shepherd, of Batopilas, but this lease was not profitable. The best ore always occurs in pockets of rich native silver; in the San Gil the ore of the vein is low grade when not in bonanza. At the San Pedro the low grade runs about 20 oz., and at Batopilas 12 oz. I saw one pocket which had been taken out of one of the Batopilas mines, on the 2000-ft. level, that was not over 80 ft. in length, 40 to 50 ft. in depth, and would perhaps average 2½ ft. in width; from this they took out \$750,000.

At one time Conness Shepherd sent to the mint at Chihuahua over \$100,000 of silver bullion that had been taken from the mine, cut out by chisels. As it must be at least 975 fine in order to be received by the mint, he refused to pay the mint tax, claiming it was not bullion, as he had never refined it. The case was taken to the higher courts and decided against him on the grounds that nature had refined it for him. These rich pockets are characteristic of the veins in the diorite. The San Gil has probably produced \$1,500,000.

Immediately below these two mines is a short gulch about two miles long which is dry most of the year, but during and after the rainy season the native miners used to wash the gravel of the creek in their wooden bateas for native silver. To this they add some lead and smelt it in a blacksmith's forge, obtaining a bullion 975 fine, which contains about \$2 gold.

Three or four miles south from Las Tajos an old trail can be followed for some distance on the mountain side. This is said to be an old trail to a lost mine, from which the ore was carried down for treatment; the mine has never been found. Two miles from Las Tajos, and 1000 ft. higher, is the old Rosario mine, worked at the same time as San Pedro-Anastacio. It is only 200 ft. deep, and has a record of upward of \$1,500,000 from a silver-lead ore, with some gold value, in andesite. Near the surface the vein was only 1 in. wide, but at depth as much as 4 to 6 ft. It appears quite likely that the production was considerably greater, as there was much rich ore stolen. There are *vasos* at many places in the vicinity where the ore was smelted, wood being used for fuel, with a 25% lead flux. The ore is easily smelted when not too base; the lead is mostly burned off and lost, leaving the bullion 975 fine. I built two of these *vasos* of sun-dried brick, but their capacity is so small, 500 to 1000 lb. per day, that it is not profitable to use them for ores of less than 60 oz. silver content. The walls of the Rosario mine are soft and much oxidized. There was a small spring in the mine from which the water was conveyed in troughs to a sump and carried out in rawhide buckets on the backs of peons. Once the miners were away at a fiesta, in Morelos, for a week and the troughs fell down, softening the walls, which caved in, killing several men including the owner's son. They are still buried, as the mine has never been worked since.

In the early nineties a cross-cut was started and driven several hundred feet to cut the vein 300 ft. below the old workings, but was abandoned for want of means. Later, in 1904, some Pittsburg people completed this adit and cut a vein; in the old workings above there were two veins, one always carrying the ore; when the vein was cut the manager only drove on it, and some small pockets were found, assaying over 3000 oz., but he did not know enough to raise or sink on these, nor to cross-cut to the other vein, which may have carried the ore at that depth. The property has been idle ever since. A mile to the right of the Rosario, at about the same altitude, is an old mine with a large dump; no one knows when it was worked. Two and one-half miles to the west, at 8000 ft. altitude, is the Balojaque mine, which was worked at the same time as the Rosario; there evidently were two ore-shoots of good length worked to a depth of 100 ft., the ores being silicious brom-

ides and chlorides of silver. The old workings are in bad condition, but samples can be obtained assaying 2000 ounces. To illustrate how easy a mistake may be made in mining, I may add that I and two associates secured the property, and I wished to run an adit on the vein, about 200 ft. in length, to get under the first ore-shoot 100 ft. below the old workings. My two associates insisted on going to the creek level and driving a long cross-cut over 500 ft., because it would thus afford 350-ft. depth. The majority ruled, the cross-cut was driven 354 ft., and we had to quit because the people associated with us would not put up any more money. Not over 2000 ft. south an Indian discovered a new vein on a small mesa, where the ore would pan a little gold. The Indian offered to sell it to my partners (I was in the States at the time) for \$100. They examined it when the Indian was not there, sampling the red oxidized streak, which proved to be low grade, but failed to sample the yellow portion of the vein that was rich. The Indian sold it to Cecilio Diaz, who did 30 to 40 ft. of work and sold it to Conness Shepherd, of Batopilas, for \$28,000. Shepherd took out and shipped 8 or 10 tons of sorted ore to Parral that averaged over 1000 oz. silver and 4 oz. gold.

At a depth of a little over 100 ft. the vein widened out.

A FARO GAME IN MEXICO.

with plenty of pyrite, some zinc, and low silver. We offered to bond it at \$25,000, but he wanted \$120,000; the property has been idle ever since. About one and one-half miles northwest of Las Tajos is the old Tajos mine where considerable work has been done, with good results it is claimed. There are several other good prospects in this vicinity worthy of development. Down the Tenerivia river, four miles below where Morelos creek empties in, is the Charcas mine, quite extensively worked by Conness Shepherd, of Batopilas. The vein is about 2½ ft. wide, but while fairly rich the ore was base, and on the whole it was not profitable. Above, on the right-hand side, is an old mine; the old Spanish records give a good report of it. Occasionally when some one re-locates it a little superficial work is done.

Below Charcas, on the right-hand side of the river, are several old mines, worked more or less during the past sixty years. Silver is the principal mineral, but there is a little gold and some lead. A little lower down the river and on the opposite side, in the granite, are several gold-bearing gash-veins, but they pinch out in depth. At the old San Miguel puebla, at the junction of the two rivers, is some placer gravel where the Mexicans wash a little gold. The content is low and the gravel was probably brought down and deposited from the San Miguel river. Back in the mountains several miles west is the old Guadalupe mine, with considerable ore containing 30 to 50 oz. silver. This was extensively worked years ago, and is now owned by a German. Not far away are two silver veins, 6 ft. wide, worked during the past ten years by some Arabs of San José de Gracia; they say the ore will average 30 oz. silver.

Farther up the river on the same side, on a high mesa near the foot of a mountain, upward of \$100,000 in native silver was taken out from placer gravel. The source of this has never been found. Up the Tenerivia river, above where Morelos creek comes in, are several other old mines carrying silver and gold. About ten miles above, near the mouth of La Dura creek on the east side, is the old Las Hiegueras mine; it has a large dump of good grade and it has a good record. During the past year the owner, a Mexican who has owned it a long time, has done some work and developed a good body of gold and silver ore worth over \$1000 per ton. Before commencing work he asked \$70,000 for it. Up La Dura creek six or seven miles there is a small gold district, and for the past thirty years considerable work has been done, mostly on the Dolores, El Rico, and San Pedro. There are several other more recent discoveries. Malaney Bros. have been there for the past twelve or fourteen years, but have always been hampered for sufficient funds. They have a small Huntington mill and have taken out considerable bullion. While the Morelos district is isolated it is possible to operate cheaply; labor is abundant and cheap, and nearly all are miners. Wood and water is plentiful, with fine pine timber in the higher mountains for all building purposes, whip-sawed and delivered cheaply (delivered for \$30 per M). The climate is fine; oranges and bananas are as good as found anywhere. Three crops of sweet corn per year can be grown and tomatoes nine months of the year for two years from the same plant. Freight can be laid down from Fuerte or Choix for 1½¢. per pound, and from Parral for 2½¢. per pound. Many of these ores could now be cheaply treated by cyanide, and it is only a question of a few years when this district, which has been quiescent so long, will be rejuvenated.

Australian Dredging

An interesting statement of the output of gold and tin from the various dredges in operation in New South Wales in 1911 is embodied in the annual report of the Under Secretary for Mines (E. F. Pittman), and abstracted by the *Australian Mining Journal*. Mr. Pittman shows that the value was £307,340, or an increase of £27,132 in value on that of the previous year. The yield contributed by the gold dredges shows a decline in value to the extent of £22,496 when compared with that of 1910, but there is an increase of £49,628 in value recorded in connection with the quantity of tin ore recovered. Since 1900 the dredges have furnished an output valued at £2,449,753. In all 71 dredges were in operation. Details are tabulated below:

BUCKET DREDGES			
	Gold.	Tin.	
Number of dredges.....	20	4	
Number of cubic yards of material treated	5,122,476	577,977	
Total quantity won.....	19,939 oz.	147 tons	
Value won	£78,192	£17,565	
Average yield per cubic yard of material treated	1.87 gr.	0.57 lb.	
Average value obtained per cubic yard of material treated.....	3.66d.	7.29d.	
PUMP DREDGES			
	Gold.	Tin.	
Number of dredges.....	9	28	
Number of cubic yards of material treated	1,260,429	2,533,782	
Total quantity won.....	5,179 oz.	1,418 tons	
Value won	£19,624	£167,284	
Average yield per cubic yard of material treated	1.97 gr.	1.25 lb.	
Average value obtained per cubic yard of material treated.....	3.81d.	15.84d.	

THIRTEEN gold-mining concessions, aggregating 10,000 acres, in the Changsong district, north Phyang-an province, Korea, have been granted to Keiichiro Yasukawa, a wealthy Japanese.

Mineral Hill, Nevada

By R. H. TOLL

Bordering the wide Pine valley, in the eastern portion of Eureka county, Nevada, is a low range of mountains in which valuable minerals in profitable quantity have been found in but one notable locality—a rounded promontory a thousand feet or so in height, which extends westward toward the valley, and is aptly designated Mineral hill. This mountain was widely known in the early days of mining in Nevada, high-grade silver ore having been discovered in 1867 by two prospectors who were searching the hills for a lost horse. Mineral hill is locally credited with a production during the next decade of four to seven millions, according to the state of inebriety of the old-timer who tells the story.

The orebodies were in limestone, which forms the capping of the hill, overlying slates of unknown thickness. All the ore was mined from the eastern end of the hill, where the limestone is thinnest, and the orebodies were irregular in both shape and content, with no apparent relation to the contact between the two formations. Narrow dikes of porphyry cut the sedimentaries from northeast to southwest, and these are probably responsible for the mineralization of the lime. The orebodies do not extend downward to the slate, all those so far discovered being quite superficial; for, though the eastern end of the hill resembles an enormous honey-comb, the greatest depth of the workings is 120 feet.

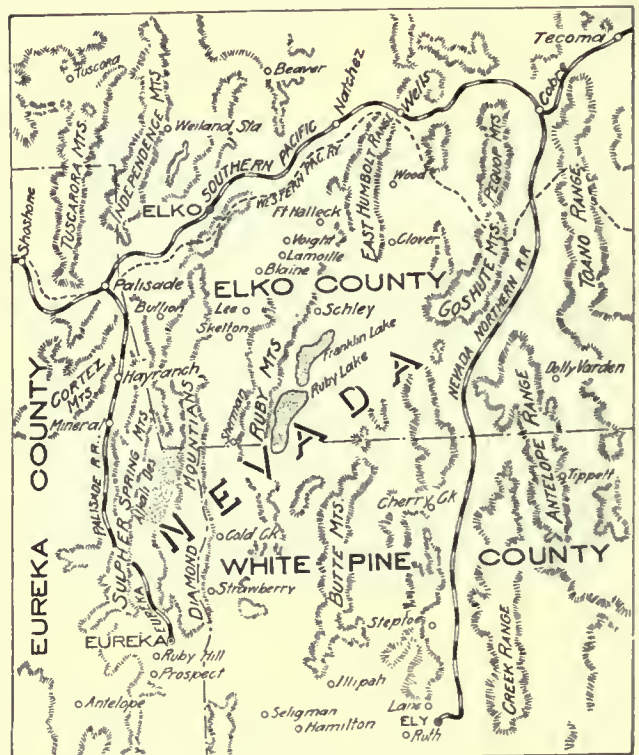

The mines were worked entirely by open-cuts and adits, and many of the stopes, as well as the cuts, are of considerable width and the ore was cheaply mined. The gangue is principally quartz, carrying 10% of lime and small amounts of iron, copper, zinc, and manganese, with traces of arsenic, antimony, and other base metals. Silver is the mineral content of value, the amount of gold being inconsiderable. In the surface ores the silver occurred chiefly as chloride, bromide, argentite, and polybasite, mixed with carbonate and molybdate of lead, carbonate of copper, and manganese. During the most prosperous times the ore contained 100 to 130 oz. silver per ton, but toward the close of the productive period the value fell to about 20 oz., after close sorting, and this appears to be the lowest grade which could be handled profitably under the most advanced methods at that time, though an extraction of 90% was made.

The treatment of these ores in the early days is a matter of historical as well as metallurgical interest, since the property was managed by no less a personage than M. Eissler, who describes the methods used in considerable detail in his valuable 'Metallurgy of Silver,' from which is taken the information here given regarding the milling process. The first discoverers of the mine shipped eighty tons of ore to Austin for treatment in the Manhattan mill by roasting and pan-amalgamation. The excellent results obtained by this method led to the construction of a 15-stamp mill, provided with a Stetefeldt furnace. The mill was situated about a half mile below the mine, and the ore hauled to it in wagons. After crushing in a Blake crusher it was dried by spreading to a depth of 4 to 5 in. on a cast-iron floor composed of plates about 1/2 in. thick. Under this floor was a system of 8-in. flues connecting with a fire-box at one end and a stack at the other. The ore was raked and turned constantly until quite dry, after which it was fed by hand to the stamps, one man attending to all the stamps.

The mortars were provided with double-discharge and 40-mesh screens; and the stamps weighed 850 lb. and dropped 8 1/2 in. 63 times per minute. The fine pulp was taken away by a screw-conveyor and delivered to a bucket-elevator of the type now in common use, which fed the furnace. This furnace delivered the roasted ore upon a cooling-floor, from which it was trammed to the pan-room; four pans and two settlers being on each side of the tram-track. Each pan was charged with 1500 lb. of ore, and water to

make the proper consistence was added, with a dipperful of sulphuric acid. After stirring for two hours 300 to 400 lb. of quicksilver was put into the pan, with 10 to 15 lb. of iron filings and borings, and the pans were run for six hours, amalgamating as much as 92 to 93% of the silver.

After a short period of operation it was found that 46% of the silver occurred as a chloride, and that this percentage could be increased to 92%, rendering roasting unnecessary. Therefore, the use of the furnace was discontinued and the ore was afterward treated by Washoe process, effecting a saving of \$5000 per month in operating expenses and permitting the handling of thousands of tons of ore which previously had been considered waste. In order to prevent the loss of silver chloride by floating away, the ore was

MAP OF CENTRAL NEVADA.

crushed dry, and about 18 tons per day was treated. The bullion produced by this process averaged about 950 fine and brought a premium at the Mint, where it formerly was penalized on account of the large amount of copper. The daily cost of operation under the Washoe process was \$220, or \$12.22 per ton.

Another mill of twenty stamps was built, but was operated on ore only a few months, on account of the failing supply. Eissler found that the tailing which had been impounded averaged about 12 oz. silver; and, having been exposed to the atmosphere for two years, some of the sulphides had been decomposed, making their re-treatment practicable, and the larger mill was altered to handle this material at the rate of 48 tons per day, making a profit of about \$20,000 from 7000 tons of tailing. As this was the first instance in Nevada of the treatment of tailing from roasted chloridized ores it is of interest in comparison with the methods in use for this purpose in later years, and with that adopted for the treatment of the dumps and low-grade ore in the mill now under construction. By reason of its record and the development of cheaper and more efficient milling methods during recent years it is quite natural that Mineral hill should have been the subject of numerous exploitations, which have been uniformly disappointing. Though the mine and dumps are said to contain a large amount of ore of profitable milling grade, the

practicability of economic extraction on a working scale remains to be proved.

About five years ago a portion of the old property was optioned by the Seenie M. & M. Co., but the panic fell on the enterprise like a wet blanket on a small flame, and smothered it before it was fairly started. Recently other property was added to the holdings of the Seenie company and the concern was reorganized as the Mineral Hill Consolidated Mines Co. Early in November last this company commenced the erection of a large mill, on the same day that marked the inception of construction work on the Eureka & Palisade railroad, which runs within five miles of the mine. Since then nearly 500 tons of freight has been hauled by wagon from Palisade, a distance of about 38 miles, and the last of the freight will be at the mill about the time the railroad is ready for operation. Instead of burning down the old mill to get it out of the way, or building a new one in a more advantageous situation, the fifteen stamps of the old-time Washoe mill were made the nucleus of the modern one, and around these have been placed parts of abandoned cyanide plants from various portions of the West, resulting in a structure which must be remodeled before it is completed. The method of treatment to be followed is probably the proper system; but the lack of design, poor construction, and the woeful arrangement of the machinery have been the despair of five engineers during the period of construction.

The ore will be trammed from the mine to a bin of 60 tons capacity, from which it will be delivered to the mill by a reciprocating gravity tramway 3100 ft. in length, two side-dump cars of 5 tons capacity being used. Thirty-five pound rails discarded by the railroad is used, and the gauge of the track is 30 in. The brake-gear is placed under the mine-bin, where it can be operated by the man who loads the cars. At the mill the cars will be dumped automatically over two grizzlies of different sizes, the one above the battery-bin having $1\frac{1}{2}$ -in. spaces, and that over the rolls-bin having $\frac{1}{2}$ -in. spaces, each grizzly being about 6 by 12 ft. and set at an angle of 30° from the horizontal. The oversize is divided between a No. 3 Gates and a No. 3 Austin crusher, which reduce it to the size of the grizzly openings, the Austin delivering to the battery-bin, and the other to the rolls-bin.

The number and weight of stamps remains the same as given above. The stamps are operated by the old-fashioned single-arm cams, and make 150 drops per minute. The screens are 4-mesh with No. 18 wire. The foundations of the battery remind one of Lincoln's joke about the length of a man's legs: It seems as if a battery-foundation ought to be long enough to reach from mortar to the ground; but such is not the case at Mineral Hill, there being a space of 18 in. between the bottom of the mortars and the top of the foundation. This is filled in with 6-in. pine blocks laid on their side, so the first few blows of the stamps will render them masses of splinters.

A set of 16 by 30 rolls receives the ore from the bin by means of a belt-driven Challenge feeder, and crushes it to about $\frac{1}{4}$ in., discharging to two 6-ft. Chilean mills, which also receive the discharge of the stamps. These mills are of special construction, similar to the Janney mills which have proved so satisfactory at the Utah Copper mill, and will doubtless be highly efficient here. A unique feature of these machines, so far as the Mineral Hill is concerned, is that some of the parts are new, every other machine in the mill being entirely second-hand. The Chilean mills will crush to 30-mesh, the pulp passing to the tables through a 6 by 8-in. launder set with a slope of $\frac{1}{4}$ in. per foot. The concentrating department comprises eight No. 3 and two No. 5 Wilfley tables, set head to head in two rows, all driven by the same line-shaft and at the same rate of speed. The line-shaft is $1\frac{1}{2}$ in. diameter, and 40 ft. in length, and, in addition to the 10 tables and 2 suction-pumps, it is loaded at the outer end with all the machinery of the sand-leaching department, consisting of a 4-in. centrifugal pump lifting 22 ft., a 7 by 6-ft. Goulds solution-pump, and two Dorr classifiers.

The tailing from the tables will be elevated to the classi-

fiers, which are set on the roof-trusses, and from the classifiers the slime will flow by gravity to the 12 by 35-ft. Dorr thickener, the sand going to six 5 by 14-ft. leaching-tanks, through a Butters & Mein suspended distributor. It is expected that three days will complete the cycle of treatment in the sand-tanks. The thickened slime will be diluted by strong cyanide-solution and flow by gravity to the agitation-tanks, which are 10 ft. in diameter and 13 ft. in total height. They are three in number, built of No. 10 steel and provided with conical bottoms. In the centre of each tank an 8-in. riveted pipe extends to within 1 ft. of both top and bottom, being held in place by light angle-iron braces from the sides of the tank. Air is conducted to the bottom of this pipe through a $\frac{3}{4}$ -in. wrought-iron pipe. In these three little tanks it is intended to treat 150 tons of slime (dry weight) per day, making an 85% extraction.

From the agitators the slime will be lifted 22 ft. by another 4-in. centrifugal pump to a 5 by 12-ft. wooden tank provided with a mechanical stirrer, from which it will flow by gravity to the Moore filter. This filter consists of two baskets of 34 leaves each, the latter being $4\frac{1}{2}$ by 6 ft. in dimensions. Goulds suction pumps are used, having 7-in. pistons and 6-in. stroke. The crane is to be operated by steam, since the small compressor will not furnish enough air for both this crane and the drills in the mine. The slime will be washed first with barren solution and then with water and discharged from the last vat by a screw-conveyor working in the bottom of the vat. The solution from the Moore filters will be clarified before entering the silver-tank by passing through an iron box similar to the ordinary zinc-box and packed with oakum. The box is so placed that each compartment may readily be flushed out by means of a hole in the bottom.

Precipitation will be effected in four zinc-boxes, each provided with seven compartments 30 in. square and 2 ft. deep. A heavy screen with $\frac{3}{4}$ -in. openings rests on wooden blocks, which holds it 2 in. from the bottom, in each compartment. The barren-solution sump is directly beneath the zinc-boxes and partly supports them. It is 10 ft. high by 12 ft. diameter, and built of No. 10 steel. The solution is returned to the storage tanks by a Deming triplex pump, size $5\frac{1}{2}$ by 8 in., discharging through a 3-in. pipe. The storage-tanks are of liberal dimensions, 13 ft. diameter by 19 ft. high, and also of steel. Two of these are to be used for standard solution, and one for wash-water, the two being primarily for the sand department, which has no sump-tanks. The barren solution and wash-water will be drawn directly from the sand by the solution pump and returned to storage or pumped into another leaching-tank, an arrangement which causes no end of annoyance when the slightest leak occurs in a filter-bottom.

Steam-power is used with coal as fuel. A Reynolds-Corliss engine runs the Ingersoll-Rand compressor and the concentration and cyanide departments of the mill, while the stamps and heavy machinery are to be operated by a 16 by 36-in. horizontal slide-valve engine which is a relic of the early days. Water for the mill, as well as for domestic use, is piped from two small springs a mile or more from the mine, which in summer will hardly supply sufficient water for domestic purposes; hence there will be great difficulty in milling during the dry season, even with most careful conservation. In fact, it will not be an easy matter for the mill to operate at any time because of the flimsy construction of the buildings and foundations. The latter are already settling and breaking, large areas of roof cave in under the weight of a light snow, and the upper trestle and ore-chute have been demolished by wind; all of which serves to demonstrate how easily a meritorious enterprise may be ruined by incompetent management.

GOLD MINES are said to have been discovered along a river seven or eight miles from Hamzuka station on the Fukuoka railway, according to the *Jiji Shimpō*. It is reported the ore averages 3 oz. gold per ton and has been estimated by authorities said to be trustworthy that \$1,000,000,000 worth of gold is within easy reach at this place.

Sulphur Trade in America

By ALBERTUS KOCH

The past ten years has witnessed the destruction of the sulphur monopoly held for many years by the British owners of the Italian sulphur mines. In the same time the United States has advanced to the position of being one of the leading, if not the dominating, factor, in the world's sulphur-mining business. The development of the great natural sulphur deposits of Louisiana is responsible for these changes. In 1900 the sulphur production of the United States, exclusive of that derived from pyrite, amounted to only 3147 tons. In the same year 167,696 tons was imported, the greater part coming from Sicily. In 1910 the production of natural sulphur in the United States had risen to 255,534 tons, and the imports from Sicily had fallen to 10,704 tons. The imports of sulphur into the United States during 1910, from all sources, was 28,647 tons. But during the same year the United States exported 30,742 long tons of sulphur. This is a remarkable contrast to the situation existing in 1900, when 98% of the sulphur consumed in the United States was imported.

As a result of the decrease of exports to America, the Italian mines are seriously suffering from overproduction, and only 380 were in operation at the close of 1910. Their stocks of sulphur on hand have increased from 310,123 tons in 1901 to 647,567 tons in 1909. As a further blow to the Italian mines, Japan has lately become the leading exporter of sulphur to America. Of the 28,647 tons imported into the United States in 1910, Japan contributed 17,377 tons, Italy 10,704 tons, and other countries 566 tons. But since Japan has so far never produced more than 40,000 tons in any one year, it is not probable that competition from that country will ever become disastrous to the industry now pretty strongly established in the United States.

The rise to prominence of the sulphur mines of Louisiana contributes an interesting chapter to the mining history of the United States, and is another fine example of success achieved through persistent scientific research and experimentation. The Louisiana deposits are in Calcasieu parish, near the town of Lake Charles. For 40 years these deposits have been known to exist, but were never, until recently, exploited successfully, though much labor and many thousands of dollars in money had been expended. Even as recently as 25 years ago the lands on which are now the best mines were sold for taxes.

The difficulty lay in finding a satisfactory method of mining the deposits. The sinking of shafts was repeatedly tried, but failed because of the overlying quicksands. A Belgian company sought to conquer the quicksand by sinking huge iron rings to shut it out. Other methods introduced by well known engineers were likewise failures, and the lands were practically surrendered. Twenty years ago these deposits attracted the attention of Herman Frasch, a German chemist then in the employ of the Standard Oil Co. in the South. After studying the difficulties, he determined on a method for mining the sulphur and formed, in 1891, the Union Sulphur Co., to undertake the work. It was through his efforts that the project was financed, the money being secured from his associates in the Standard Oil Company.

Mr. Frasch's method of mining the sulphur has been described heretofore in the technical press, but the following short review may here be given: A large bore-hole was sunk, as in drilling for petroleum, and in it four pipes concentrically arranged were let down. The outer pipe is 10 inches in diameter, the next 6 in., the next 3 in., and the fourth is 1 in. The operation consists of forcing down the 3-in. pipe hot water and superheated steam at 330°F., to melt the sulphur. Compressed air is driven down the 1-in. pipe and bubbles into the melted sulphur and water. The specific gravity of the mass being greatly diminished, it rises to the surface through the outer pipes.

It is then run off into large rectangular tanks made of rough planking. Some of these are as large as 350 by 250 by 40 ft., and they are so arranged that railroad trains can pass between them. After the sulphur cools and solidifies it is broken up and prepared for shipment.

With the solution of the question of mining, the troubles of the company were not by any means over. It was necessary to build a railroad to connect with the trunk lines, and to build and operate a line of small steamers to get the sulphur to tidewater. Then when production was finally started the company found its most likely markets in a precarious condition, because of a move on the part of the British owners of the Italian mines to crush this new enterprise and save their own monopoly. For almost a decade the Union Sulphur Co. fought the foreign combine. Though the public knew little of this industrial conflict, it was an exceedingly important one and meant either the destruction of a promising American industry or American control of the sulphur industry of the world. Inch by inch the Louisiana company won its ground, until it has practically driven Italian sulphur out of the American markets. The Union Sulphur Co. now controls practically all of the proved sulphur deposits in Louisiana, and while it is a close corporation, giving out no figures on tonnage produced or costs of production, it is known that it is yielding at the rate of close to 400,000 tons per year, and is capable of increasing this production at any time to 500,000 tons per year. The costs of production are estimated at \$6 per ton. Production was begun in 1901, when the yield was about 40,000 tons. The yield has steadily increased to the figure given above.

This one company produces 98% of the natural sulphur output of the United States, and the product is approximately chemically pure, needing no refining. It seems justifiable to prophesy a further rearrangement of the sulphur business with the completion of the Panama canal. At the present time 60% of the sulphur imported into the United States is entered at Los Angeles, San Francisco, and Willamette, Oregon, and comes from Japan. With cheaper transportation, the sulphur from Louisiana will doubtless displace the Japanese product and be in supreme control of all American markets. It has already cut down imports into Atlantic seaboard points to about 5000 tons per year.

The Chilean Andes, Mexico, China, India, and the Philippines are known to have good deposits of sulphur, but in the light of present knowledge they can hardly expect to compete with Louisiana, where the deposits are known to be of enormous extent and the costs of extraction remarkably cheap. It is appropriate to close this article with the statement that Mr. Frasch, who has rendered such signal service to the sulphur-mining industry of America, recently received from the New York section of the Society of Chemical Industry the Perkins medal in recognition of his work in connection with the development of the Louisiana sulphur deposits.

Natural Gas

The United States Bureau of Mines has been investigating the composition and use of natural gas. In a recent address before the Natural Gas Association of America, George A. Burrell, of the Bureau, pointed out that in natural gas carbon dioxide may range from a trace, as in the gases of western Pennsylvania, to as much as 30% in gas obtained from Kings county in southern California. Nitrogen may occur in quantities ranging from a few tenths of 1% to as much as 10 or 15%. As an example of an unusual and extreme case, a natural gas occurring in the state of Washington contained 98% nitrogen. In general it may be said that those gases issuing under considerable pressure in the great fields which are providing heat and light for many towns consist of paraffine hydrocarbons in which methane predominates along with smaller quantities of ethane and traces of the still higher paraffines. These gases range in heating value from 900 to 1100 B.t.u. per cubic foot at 0°C. and 760 mm. pressure, with the average

more nearly approaching the latter figure. In these days when the heating value is the important factor in determining the usefulness of a gas, such high values are very significant.

The Bureau has issued one publication having to do with the properties of liquefied natural gas. In the production of gasoline a great waste has occurred, because in order to make condensates safe for shipment, the lighter products have been allowed to evaporate. The confinement of the material in iron cylinders for use as a bottled gas is now receiving attention. A gas is produced which has a heating value of at least 2200 b.t.u. per cubic foot, and a candle-power of about 45 when burned as a naked flame at the rate of 5 cu. ft. per hour. The use of a mantle will, of course, increase this lighting effect greatly. I. C. Allen and Mr. Burrell bottled in strong cylinders the condensate obtained by applying a pressure of about 500 lb. to the square inch and a temperature of 0°C. to crude gas obtained from wells at Follansbee, West Virginia. This could easily be done with casing-head gas which is at present going to waste. In the case of the exceedingly rich gas obtained at Follansbee, about 50 cu. ft. of gas per gallon of liquid was realized. Millions of people are so situated that gas is not used by them, but if bottled gas sold at a reasonable price becomes available, the outlet for the material will be large. One company is already in the field for the purpose of exploiting the liquid gas. The new product has been named 'gasol.'

Copper Smelting at Kyshtim

By V. P. ASSAIEFF

*Production of copper in Kyshtim began in 1907, but smelting in appreciable quantities began only in 1908. This was at the Soimonoffsky plant. It was subsequently determined to construct a new copper-smelting plant on Karabasheffsky hill with large water-jackets and converters, and also to build a large electrolytic refinery at Lower Kyshtim. It was proposed to produce 400,000 poods of copper per year. In September 1911 I saw at Karabash two new water-jacketed smelting furnaces, and a third similar furnace is now being built, smelting 25,000 to 30,000 poods of ore per 24 hours. The matte obtained is turned to blister copper in two 40-ton converters. At Nizhni Kyshtim the largest Russian electrolytic refinery has been built with a daily capacity of 1000 poods of copper, to be almost doubled, it is said, by the installation of new electric machinery. Just recently at Upper Kyshtim a Siemens' regenerative furnace, 145 ft. long, has been built for smelting fine ore and flue-dust.

Between the smelters and the mines a railway has been laid down, and a locomotive (steam and electric), electric cranes, and pneumatic lifts, are at work. The principal operations are as follows:

Karabash plant—

1. Pyrite smelting in large water-jacketed furnaces to matte with 25 to 35% Cu.
2. Converting the matte to blister copper with 99% Cu in large converters.

Lower Kyshtim plant—

3. Refining blister copper and casting in anodes.
4. Electrolytic refining of copper and extraction of gold and silver.

Further important operations carried on are:

Upper Kyshtim plant—

5. Smelting fine ore and dust in large Siemens' regenerative furnaces.
6. Smelting of poor matte in small water-jacketed furnaces.
7. Converting concentrated matte to blister in small converters.

The board is sparing no expense in the search for the required ore reserves. The requirements will reach 90,000 to 100,000 poods per day. On this 400,000 rubles have already been spent, and 300,000,000 poods of ore of 3%

copper content have already been proved. Other 200,000 rubles will probably be spent this year, and five diamond-drills, two for 500 and three for 1500-ft. holes, are now at work. Three more 1500-ft. outfits may be bought this year. Most of the ore is now produced at the Konyuchovsky mine, then at the Smirnoff and Tisoff mines. Fortunately there is abundance of fluxing quartz and limestone at Kyshtim. The quartz assays 92 to 96% SiO₂, and the limestone 53 to 54% CaO. The pyrite smelting is done with very little coke, at most 1 to 1 1/4% of the mixture or 1.5 to 1.7% of the weight of the ore, so the annual consumption of coke does not exceed 300,000 poods. It comes from south Russia, England, and Germany, the cost being about the same. Wood is used for the boilers and furnaces, but recently lignite from the Cheliabinsk region is coming more into use.

Copper is now produced in the Karabash, Lower Kyshtim, and Upper Kyshtim plants. The first plant was begun in 1909, and it started full work in January 1911. The chief dimensions of the furnaces are 22 ft. long, 4 1/2 ft. wide, and 19 ft. high. There are 52 tuyeres to a furnace, of which 47 to 48 are always in use; the blowers are of about 600 hp. each, and give 30,000 to 35,000 cu. ft. per minute, under a pressure of 6 to 8 in. mercury column. The blast is cold, and 40,000 to 50,000 cu. ft. is used to 1 ton of mixture, or 50,000 to 60,000 cu. ft. to 1 ton of ore. Gas and dust pass through two wide flues. About 5000 poods of dust is extracted per day with a content of 2.8 to 3.5% copper; thus about 50,000 poods of copper (value 500,000 rubles) is recovered per year. The third furnace (now building) will have the capacity of its dust-trap more than double that of the others.

The efficiency of the water-jacketed furnaces is as follows: The mixture in July 1911 for both furnaces was ore 75%, quartz 15%, limestone 5%, coke 1.25%. The quantity of mixture smelted was 2,010,276 poods, of which 1,512,397 poods was ore. The resulting matte was 135,448 poods, dust 159,530 poods, and slag 1,282,620 poods. The average analysis of the matte was copper 26.53%, iron 41.4%, and sulphur 25.1%. The total of sulphur in the mixture was 608,593 poods, of which 5.63% passed into the matte, 4.38% into the slag, and 1.76% into the dust. The result is considered to have been very satisfactory and to quite justify the expenditure involved in construction of the plant.

To convert the matte into blister copper two Pierce-Smith 40-ton converters are installed at Karabash. From the quantity treated in July 1911, 101,669 poods matte and 24,284 poods of copper was produced. The average copper content of the matte was 26.5%. The special laboratory at Karabash employs five chemists, who made 2500 assays last August.

The blister copper from the Karabash and Upper Kyshtim plants are treated at the Lower Kyshtim electrolytic works. The blister copper is smelted into anodes in regenerative furnaces with wood gas, and the output is 2400 poods of copper re-smelted per 24 hours. One cubic sagene of wood gives 425 poods of anodes averaging 99% Cu.

The electrolytic plant is a large one-story building with 396 baths of wood, lined inside with lead 41.5 in. deep, 27 in. wide, and 68.5 in. long, in twelve series of three rows of eleven baths each. Each bath contains 9 anodes and 10 cathodes; the former are now being increased to 12. The current in the bath is 0.3 volts. The Upper Kyshtim plant provides the current by gas engines. The electrolyte consists of a solution of sulphate of copper and free sulphuric acid—solution 1.2 sp. gr.—which is led into the bed of the baths and rises up to be siphoned into subsequent series. Thanks to the purity of the anodes, the electrolyte has not been changed since starting the plant. The Upper Kyshtim plant is now an auxiliary one. At Kyshtim there are millions of poods of fine ore besides the millions of poods of dust from the furnaces, the annual production of which, at Karabash, is calculated at 2,000,000 poods. To smelt these and the fine ore a large Siemens-Martin furnace has been built.

*Translated by the Mining Journal from the Gorny Journal.

Flotation of Zinc Ores in Japan

By TADASHIRO INOUE

The Kamioka mine of the Mitsui Mining Co. is the principal producer of zinc in Japan. Up to the present ore has been marketed in the form of concentrate which has been shipped to Europe, but a smelter is now being built and it is proposed to make spelter for the local market. The mine is in the provinces of Hida and Etchu, the offices and principal works being about 35 miles from Toyama on a branch of the government railway. The property is said to have been opened twelve centuries ago, but was worked only on a small scale until purchased by the present owners in 1888. Now there are extensive underground workings reached by adits, and two large ore-dressing works, at Shikama and Mozumi, respectively, 10 miles apart. The ore is a mixed sulphide, occurring in irregular bodies metasomatically replacing limestone lenses in

of wood, and is 5 by 2 ft. in plan. It is separated by a wooden partition into two parts, of which the second, 5 ft. deep, is the deeper. At the bottom is a hard-lead cock. The heading and tailing tanks are 6 by 6 ft. and 5 ft. deep. They are made of wood and have false bottoms, through which the solution drains, being carried to the solution-storage tanks by means of a stream of water. The solution-feed and storage tanks are all made of wood, and are approximately 6 ft. deep and 6 ft. in diameter. About 16,500 lb. of material is treated in this plant in 10 hours. This corresponds to about 4% of the raw ore coming to the dressing plant. The feed, mixed middling from Wilfley tables and buddles and floated material from classifiers, contains 20 to 30% Zn. The product from the flotation plant assays 45 to 50% Zn. While finer material may be treated, the best results are obtained from ore between 50 and 100 mesh in size. The extraction is computed as 80% of the zinc, and the final tailing assays 5 to 6% Zn. The output amounts to 50 or 60 tons of zinc product per month. Following are analyses and sizing tests of the material treated:

ANALYSES OF MATERIALS TREATED

	Jig Middling, %.	Wilfley Middling, %.	Buddle Middling, %.
Pb	0.47	0.40	0.28
Cu	0.18	0.19	...
Fe	4.27	4.93	5.00
Zn	24.13	27.32	34.90
SiO ₂	35.74	34.00	28.40
Al ₂ O ₃	6.74	4.88	2.80
CaO	1.18	2.46	3.00
MgO	0.71	0.46	...
S	16.26	20.22	...

SIZE OF MATERIAL TREATED

Mesh.	Wilfley Middling.	Buddle Middling.
50- 80	4.6	...
80-100	21.3	...
100-120	13.9	0.7
120-150	10.1	1.3
150-180	18.4	2.7
180-200	7.9	4.0
200	23.8	86.7

The jig middling is 30 mesh and finer in size. The distribution of the zinc in the jig middling is shown by the following representative sets of analyses:

	Sample A.		Sample B.	
	%.	Zinc, %.	%.	Zinc, %.
30	11.0	28.0	14.6	25.5
30-50	28.2	26.0	34.2	22.7
50-70	48.7	22.2	41.9	21.8
70	12.1	22.5	9.2	21.7
Total	100.0	23.9	99.9	23.0

The following results for the period extending from May to November in 1911 may be quoted, the figures being in kan, equal to 8,2673 lb. each:

	Amount.	Zn, %.	Zn Content.
Feed	695,703	21.9	152,577
Product:			
High-grade concentrate...	143,207	52.7	75,450
Low-grade concentrate...	102,393	45.6	46,665
Total	245,600	49.7	122,115

Extraction 80 per cent.

The expense for treating 695,703 kan (about 2880 tons) in the same period amounted to Y43,590.14; equal to Y6.28

FLOW-SHEET OF MILL.

rocks of presumed Archean age. One ore-shoot in the Tochiho mine has a maximum cross-section of 50 by 300 ft. and has been mined for 1000 ft. in depth. The Tochiho ore contains 1.3 to 2.5% Pb, 10 to 16% Zn, and from 3 to 4 oz. of silver per ton. The output is about 10,000 tons per year. The ore as it comes from the mine is treated in wet-concentration plants by means of classifiers, jigs, buddles, and tables. Argentiferous lead and zinc concentrates are produced, and a zinc middling, which is re-treated in a flotation plant. The lead concentrate is roasted in reverberatory furnaces and pots, and smelted in blast-furnaces. The rich lead is liquated and desilverized. The matte is roasted and refined by the *mabuki* process.

The flotation process used at the Kamioka mine was developed locally along lines described in Potter's 'Principles of Flotation,' the principal difference being the introduction of heavy oil in the heated and acidulated solution. During treatment the solutions are kept at 80 to 85°C. In making up the solution, 12 lb. of H₂SO₄ of 54°B. is used for 100 kan or 826¾ lb. The dilution is about 2:1 of solution to ore. Of the crude ore, 0.09 to 0.14 gal. is used for the same quantity of ore. The scheme of treatment is shown in the figures above.

The pointed box in which the separation occurs is made

per 100 *kan*, or about \$7.50 per ton. The principal items were:

Labor, days pay	Y 5,277.03
Labor, contract	2,448.86
Materials	34,324.66
Repairs	1,195.46

Miscellaneous	21.06

Cyanidation at Treadwell

Gold ores at the Treadwell mines yield about half their value by amalgamation. In the case of the Alaska Mexican, the average percentage of recovery as free gold has been 46.66. In the mill of the 700 Ft. Claim the percentage has been 52.95. From the plates the pulp goes to vanners and the remaining saving is in the form of a gold-bearing pyritic concentrate. Formerly this was shipped to Tacoma for smelting, but now it is treated by cyanidation in a plant on Douglas Island, owned jointly by the Alaska Treadwell, Alaska Mexican, and Alaska United companies in the proportions of 60, 20, and 20%, respectively. The plant was described in 1911* by W. P. Lass, the capable superintendent, and the description need not be repeated. In the reports of the Alaska Mexican and Alaska United companies now available, the following interesting details regarding operation for the first half-year are made available:

OPERATING COSTS PER TON, MAY 16 TO DECEMBER 31, 1911

Milling at the Butte & Superior

At the new plant of the Butte & Superior Copper Co., Butte, the ore is dumped into the bins at the collar of the shaft, and fed into a crusher which reduces it to 4-in. ring. Thence it is carried by a conveyor belt to the secondary crusher at the head of the mill, where it is reduced to 1½-in. mesh. This is for the purpose of insuring a uniform mill-feed, both as to grade and size. From the secondary crusher the ore is automatically conveyed to the mill storage-bins, of 2000 tons capacity, which may be increased to 8000 tons at small expense. The ore is distributed uniformly throughout the length of the mill storage-bins by a mechanical traveling tripper. The crushed ore is withdrawn from the mill storage bins on apron feeders which dump it upon a third conveyor belt, and it is then fed to a set of rolls which reduce it in size to 5 mm. From the rolls the ore is elevated to the Richards-Janney hydraulic classifiers, and the larger sizes of ore are fed to the coarse jigs. The coarse jig tailing is then re-ground to 1½ mm. in the Chilean mills, and from there are conveyed to another set of Richards-Janney classifiers and the product goes to the fine jigs. All of the jigs are of the Harz type and have been adopted after thorough tests.

The tailing from the fine jigs is reground in the tube-mills and is conveyed to six large settling-tanks, each of which is 28 ft. diameter and 14 ft. high. In these tanks the jig tailing is combined with the overflow water from the hydraulic classifiers and settled to a thick pulp. The cleared overflow water is returned to the mill system and used over again and the pulp is drawn off from the bottom of the tanks and is ready for treatment in the flotation plant. The flotation plant consists of a heating box, mixing-boxes, and a spitzkasten. The ore is slightly heated and mixed with oil in the mixing-boxes and then decanted into the spitzkasten, where the gangue settles to the bottom. The concentrate is discharged into a launder by which it is conveyed to the concentrate-bins. In the concentrate-bins it is thoroughly dried, the water running off through screens. The concentrate from the coarse and fine jigs is re-treated in a set of cleaner jigs for the purpose of raising the grade from 45% to 50 or 55%. These concentrates are also carried by the launder to the shipping bins. The tailing from the cleaner jigs is sent to the tube-mills for further grinding and then to the flotation plant. The lead content of the ore is removed on three Willey tables, the only tables used in the mill. It will be remembered that the Butte & Superior was started as a copper mine but proved in depth to be a zinc mine. The zinc mineral is practically free from iron, making its concentration easy.

Bolivian Placers Again

The contradictory reports regarding the Tipuani placers in Bolivia give especial interest to the following extract from a letter published in *The Union Democrat* of Sonora, and written by R. T. McNeeley, W. E. Trosper, J. J. Seofield, and G. B. De Ferrari, four experienced California prospectors who visited the region this spring. The men feel that there are large opportunities in the country for experienced men properly financed, but warn all others against making the long and expensive trip. The excerpt is from a report to the partnership grubstaking the party. "As you all know, we started for the Bolivian goldfields on the strength of the Ferguson letter. On our arrival at La Paz we found that letter to be a fake. Naturally, we were much discouraged, but after careful investigation found that the great wealth of the Incas came from Bolivia and especially the Tipuani region. Therefore, it was reasonable to suppose, knowing that they had never been able to get below the water-line, that if a dredge could be put to work in some of those rivers—and there are many of them—we would undoubtedly find pay-dirt and lots of it. About this time, F. G. Schultz, knowing that we were there on a mining expedition, came to us with a proposal. He had his eyes on this concession for some time, but not having the capital to handle it himself, had simply been waiting for an opportunity to handle it on a royalty basis. He at one time was manager for the Boston Bolivian Rubber Co., and had gone up and down this river many times, panning all along, and had always found good prospects wherever he had worked. He spoke very highly of it and said if we could get a dredge in there our fortune was made. However, we were skeptical; it sounded too good to be true; but after discussing among ourselves and making more inquiries, we decided to go and look at the property. We were among the eight out of over a hundred who went into the country.

"We prospected all the way in, with indifferent success, and as it was too rough for dredging, we were not very favorably impressed. We finally reached the village of Guanay, where the Tipuani and the Mapiiri rivers run together, forming the Rio Kaka, and it is on this river that this concession lies. We immediately made camp and started work, and, to our great surprise, found that Mr. Schultz had told us the absolute truth in every way. Every pan of dirt prospected from twenty to thirty colors. We could not get below the water-line, but ground that will prospect in this way on the surface will undoubtedly be very rich at bedrock. After doing all we could on this end, we immediately tried to get a boat, as we wanted to go the full length of the concession, and there are some places on the river where the banks are perpendicular, so it is impossible to get down except by boat. We were unfortunate in this, as we got to Guanay just when every available boat had gone down the river with cargo to the rubber plantation and would not be back for at least two weeks. We talked it over and decided to stay and wait for the return of boats, but on looking over our stock of provisions, which had become very much depleted owing to rains and mules falling over the bank, we found it would be impossible. We had already prospected about two miles and found it all the same.

"Realizing that we had something good, we hurried back to La Paz to see if there was any opposition. On our arrival there we found everything moving in good shape, with little chance of opposition. We intended sending a cable explaining, as we had sent for a code and expected to find it with W. R. Grace & Co., but for some reason it had not arrived. It would have taken two or three pages to explain without a code, and even then it would have been indefinite. We discussed the advisability of one of us staying, but as it would be two or three months before anyone was needed and it would not cost any more to come home than to stay there, and furthermore, as we didn't know for sure whether you could handle a proposition of that size, we thought it best to come home and

give you the facts in person and assist in any way that we could in forming a company. If you wish to go ahead, we are ready to go back at any time and serve the company in any way that we can.

"We left Mr. Price and his partner at Tipuani working on a hydraulic claim. We were informed by responsible people that a great deal of money has been taken out at this place by divers, and we believe that Mr. Price and his partner have a good chance to 'make good.' Our concession starts 20 miles below where they are and is about 30 miles long. Beginning there an English company has a concession and is trying to operate a small dredge, but as it had to be packed in on mules it is a small affair and breaks down every time they start. They have raised a lot more capital and intend to go ahead."

Gold Discovery in Venezuela

By W. HENDERSON

*Some rich discoveries of gold have been made in the interior of Venezuela. One, in the municipality of El Callao, not far from the Yuruari river, has been named *Salva la Patria*. It is calculated that up to April 15 this mine has yielded over 35,000 oz. of fine gold. During the month of March more than 6000 oz. arrived at Ciudad Bolivar, and in the first two weeks of April the arrivals amounted to more than that, and the gold is coming in all the time. Near the Caroni river and also in the Paragua district gold has been taken out, but not in such large quantities. The extremely low level of the water in the Caroni river caused a small island to appear in its course, and from this some gold was taken; but the river is now rising and has covered the island, so that work there has necessarily ceased.

The following statement appeared in a letter from a merchant in the interior, in which he writes about the *Salva la Patria*:

"There are two *barrancas* (shafts) dug by a group, which are simple pools of gold. I have seen eight pieces of more than 40 oz. each, all containing more gold than rock. With such *barrancas* the greatest disorder prevails; outside people get in at night and have taken out more gold than the owners themselves, who have had to fence up the approaches and have an armed guard at night."

Of course the Government will soon restore order, and one does not now hear of any disturbance. There are some 2000 men digging or exploring around the *Salva la Patria*, but of course not all are successful. From what I understand, the gold is found in pockets or chimneys 50 to 100 ft. down, and not in true veins. Permits to work may be granted by the *jefe civil* (mayor) of the district; afterward the titles must be taken out in Caracas from the national government. The maximum permit is for 200 hectares (494.2 acres) and for a term of 90 years. It is a well known fact that the interior of Venezuela, even where gold has been discovered, has not been adequately prospected, and the larger part has not been explored, so these discoveries will probably continue. The gold now coming in is of a high fineness, and there is little expense in getting it out; but on account of various difficulties and high freight rates, due to inadequate facilities, a quartz mine has a hard time trying to make both ends meet. A concession has been granted for a railway into this part of the country, but English capital is desired, rather than American.

The only companies now working are the Gold Fields of Venezuela, an English concern which has not paid any dividends, but which is bringing in machinery and securing surrounding mines at low prices; and a French company which is opening the La Experiencia mine, situated between El Callao and Guasipati, with shafts and galleries, and expects to begin working in a few months. The old El Callao mill is crushing some quartz for private parties and is working the sands with the cyanide process. The directors of this group of mines have at last adjusted all their difficulties with the Venezuelan shareholders and propose to reorganize with a French company.

*From a consular report.

The Salida Smelter

By GEORGE J. HOUGH

The smelter of the Ohio & Colorado Smelting & Refining Co. at Salida, Colorado, is one of the most important reduction plants in the West. The works are about two miles west of Salida, on the line of the Denver & Rio Grande railroad, and are amply provided with tracks and switching facilities. The power-plant consists of one 500-hp. and one 300-hp. Corliss engine, which are served by a battery of five boilers. There are two No. 7 and two No. 8 Connersville blowers, and one engine and two blowers are used for each pair of furnaces, the two blowers delivering into one bustle pipe. The engines also furnish power for the pumps, but a large part of the power required for the plant is purchased from the local electric power company, as the samplers, the roasters, and the crushing departments are all run by electric motors. The sampling plant is complete, and has a capacity of 100 tons in 10 hours, or about three cars of ore can be sampled in one shift. A 1/10 shovel sample is taken from the cars and put through the crusher; in the case of large lots, the sample is cut down by a Vezin sampler to one-fifth, then

SALIDA PLANT, OHIO & COLORADO S. & M. CO.

passed twice through rolls and cut with a small Vezin sampler, giving 1/20 part of the original lot. But small lots, after the preliminary crushing, are crushed by rolls and then cut on the small sampler. This sample is then coned on the iron sampling-floor, and 1/5 taken in the usual manner; it is then crushed by 12 by 18-in. rolls to about 20 mesh, and cut down on a large split sampler to a few pounds in weight, duplicate samples being taken. The samples are dried 24 hours in a steam bath, ground fine in a cone-mill, then taken to the sample-room and cut down to a few ounces in weight, which is pulverized to pass a 120-mesh screen. While the ore-supply comes mainly from Colorado, ore is also received from neighboring states, Idaho furnishing a good deal of high-grade galena ore. Leadville furnishes the iron oxides for fluxing, and considerable silicious sulphide ore; the limestone used comes mainly from Garfield, a few miles from Salida, and does not carry any gold and silver. All sulphide ores are bedded before roasting, and the bedding system is very elaborate; on each side of the series of beds are the railroad tracks, while the beds are crossed at short intervals by small lateral tracks, making it easy to distribute the ore. The bedded sulphide ore is conveyed in mine-cars to the Godfrey roasting-furnaces; these are round brick furnaces of the moving-hearth type, and each has a capacity of about 35 tons per day. The sulphur content is reduced to 15%. From the Godfrey furnaces the roasted ore goes directly to the Dwight-Lloyd sintering machines, of which there are four; three large machines 48 in. wide and one small machine 36 in. wide. The improved Dwight-Lloyd machine has a moving grate similar to an endless belt, and having a width of 36 to 48 in. and a length of about 15 ft.; the ore is fed automatically on to the grate from a hopper, in such a manner as to give a uniform layer several inches thick. The charge passes under or through a fire-box with a down draft, setting up an intense roasting and sintering action in the layer of ore for a few minutes, after which the glowing sinter travels slowly for a distance of about 10 ft., when it is discharged from the grate as it revolves; the movement is slow, giving ample time for the sintering

reaction and part cooling of the ore, which is discharged directly into steel cars. The sintered ore has about 5% sulphur. The capacity of the large-sized machine is about 85 tons daily.

In the smelting department there are four blast-furnaces, two with a hearth area of 45 by 144 in., and two 45 by 180 in.; the furnaces are run in pairs of one small and one large furnace, the two being served by one blast-main and having a capacity of about 420 tons per day; the blast pressure varies from 30 to 36 oz. The furnaces are fed by hand. Slag is tapped into large matte settlers, and the overflow is received in slag-pots mounted on trucks which are hauled by electric locomotives to the dump. The lead is tapped into small bullion pots carried on trucks; the dross is skimmed off, and the bullion cast into bars to be shipped East for refining. The plant employs about 275 men; with the exception of the foremen and superintendents, the majority of the employees are foreigners, Austrians predominating.

Working Cost and Profit on the Rand

JOHANNESBURG CORRESPONDENCE

The question of how to increase the profits on the Rand continues to attract attention. Undoubtedly the fall in the average grade last year from 28s. 6d. to 27s. 7d. was, in face of the steadily increasing costs of the two previous years, namely 1911 and 1910, a serious question, but at the meeting of the institution of local engineers a speaker attributed more than one-half of the decline in grade to the unbridled scramble for tonnage during the year on the East Rand Proprietary Mines. When, however, the same speaker came to deal with the 5d. increase in the working costs the effect of this unbridled scramble for tonnage in sending unprofitable ore to the mill was totally ignored, but it is clear that if in this particular instance this practice had the effect of lowering the average yield it had likewise a similar effect on the average working cost. Probably the chronic scarcity of native labor and power troubles had something to do with the increased cost of last year, but what is more important in the gold mining industry today is the fact that now, when the native supply is increasing, the average working costs are not coming down, having increased during the first two months of the year to the extent of 9d. per ton. It must not, however, be overlooked that owing largely to the starting up of several better grade mines and the adoption of cleaner methods of mining, the average value of the ore milled has increased from 26s. 8d. per ton last August to 28s. 3d. per ton in February, an improvement of 1s. 7d. per ton. Such an improvement is encouraging in showing that since August a better grade of ore has been sent to the mills, which may, to some extent, be due to the scramble for low tonnage costs having been restrained. If, however, working costs during that same period are studied, a good deal of the encouragement disappears, for they have increased 1s. 5d. per ton, so that the net gain was only 2d. per ton. Still a net gain of 2d. per ton makes a total gain on the Rand of nearly £300,000 per year in the working profit, while a similar gain can be produced by lowering the working cost in a legitimate manner. Most engineers will agree that, with honest mining on the Rand, it is easier to lower the costs than raise the grade without being accompanied by more than a corresponding increase in the tonnage costs, so that it is in this direction of more economical mining that efforts are needed.

THE Messina mine, owned by the Northern Transvaal Copper Co., has produced to June 30, 1911, 65,788 tons of ore, yielding 9700 tons of concentrate assaying 53% copper. The estimated ore reserve to the eighth level is 430,000 tons, which, it is estimated, will yield a profit of £600,000. It is proposed to erect a smelting plant, capable of treating 120,000 tons per year, at an estimated profit of £150,000. The company has issued £250,000 6% debentures, and the Camp Bird, Ltd., has guaranteed 5 years' interest on these debentures.

Unwatering a Mine Under Difficulties

By C. B. WHITWELL

The mine at which the work here described was done is a small property in Yuba county, California. It was bonded several years ago, and a shaft sunk to a depth of 350 ft. along the vein, the real object being to intersect a parallel vein of greater dip at the 800-ft. level. During the sinking of this shaft a first-class mine plant was erected including 65-hp. and 30-hp. Western gas-engines, to furnish power for the 5-drill air-compressor, a 5-stamp mill, rock crusher, and a Cornish pump capable of lifting 75 gal. per minute. At the 350-ft. level the vein became flat. By survey the vein, which it was desired to intersect, was determined to be less than 150 ft. away, providing the flat pitch continued. Unfortunately, the cylinder of the large engine cracked, and the company, having expended all its funds in erecting the machinery and stamp-mill, was unable to get a new cylinder on credit. The mine was kept free of water for two months, but finally allowed to fill. This caused forfeiture of the bond.

Before closing down, the owner employed men to overhaul the machinery and place new pump-rods where needed. With everything in first-class condition, and with a complete plant, it was but a short time before the property was again bonded. Before signing the bond, the machinery was examined and found to be in good running condition and the pump in first-class working order. In fact, everything appeared to be favorable for unwatering the mine in a very short time and at a small expense. The water had risen to within 25 ft. of the collar of the shaft. Accordingly, pumping was started and everything went along far ahead of schedule time for three days. At midnight of the third day, the night man entered my room with the information that everything was running smoothly but that the pump was throwing no water. The only conclusion seemed to be that the pump-rods had worked loose and become disconnected. As there was no break above water, there was no remedy for the trouble save to go about getting the water out in some other way. A skip was ordered. By the time this was operating, the mine had filled again, the water having been lowered over 100 ft. The skip handled the water nicely for the first 80 ft., then trouble began, as it constantly jumped the track. A day was spent in repairing the track.

The next trouble was the impossibility of trying to get the skip past a post which was set out of line with the others and so close to the track that the pin holding the bale to the skip would not pass. This necessitated the arduous task of sawing out a piece of the timber under water. Matters continued to move along again until the level was reached to which pumping had been carried. The skip would apparently fill all right, but rose from the water off the track. At first this was thought to be due to hitting the water too hard, so that the skip floated. After several unsuccessful attempts to hoist, I made an under-water survey and discovered that a rail had been carefully removed. Several schemes were tried for spanning this gap, but without success, and therefore hoisting by skip was discontinued. A small Hooker pump was immediately borrowed nearby, attached to the hoisting cable, and lowered on trucks to the water's edge. As the shaft was equipped with a 2-in. air line, this was disconnected near the water and 50 ft. of air hose attached. As fast as the water lowered, the pump was let down by the hoist, and extra lengths of column pipe added at the top. By using the air hose, very little time was lost, as it was only necessary to screw on an extra length of pipe every 20 ft. for the first fifty.

Fifteen feet below the point to which the water had been lowered by the Cornish pump the break in the rods was discovered. Evidence indicated that the nuts had been removed from the bolts and the bolts had worked out. Otherwise the rods were in good condition, were quickly connected, and pumping was resumed with the Cornish

pump. Directly opposite the break in the rods was the space in the track formerly occupied by a rail. This rail had been removed and carried away. Unwatering a mine could not have been started under more favorable conditions. Everything indicated that the cost and time of unwatering would fall well within the limit of time allowed. The possibility of the human race producing an individual mean enough to perpetrate such a piece of work had not been taken into account; an act all the meaner since he had been employed and paid to fix things up in first-class shape. I suppose there are some who would say that he had done so.

Hoisting Ropes

A thorough study of hoisting ropes has recently been published in *Glückauf*, which may be summarized as follows:

(1) The productive efficiency of lubrication has not been clearly proved except in dry shafts. This suggests the conclusion that the present lubrication process for wet ropes leave room for improvement, though it is certain that all known lubricating agents rapidly disintegrate in shafts with acid or salt water. Future experiments in this direction may provide a remedy. (2) Galvanizing or coating with zinc does not appear to have had a really protective efficiency in wet shafts, the reason being probably that zinc coating has but little power of resistance to salt water. It is also suggested that the wires have suffered by the galvanizing process, for, though it has been proved by Winter and others that that process, when properly and carefully executed, does not unfavorably affect the ropes, it is also well known that it often reduces the tensile strength of the rope by 50% and even more. (3) The efficiency of ropes in dry shafts stands in the proportion of 100 to 60 or 70 as compared to wet shafts, which, in view of the high prices of ropes, means a substantial economic advantage for dry shafts. (4) Tensile strength between 160 and 180 kg. per square millimetre does not unfavorably affect the flexibility or hauling strength of the ropes, while ropes of more than 180 kg. per square millimetre have given substantially lower efficiency figures. (5) The greater or lesser strain, as expressed by a higher or lower safety factor, put upon ropes has had no influence upon their efficiency. It may therefore be assumed that the advantages of a higher safety factor are neutralized by its disadvantages, namely, greater rope thickness combined with reduced flexibility and greater dead weight.

United States Quicksilver Production, 1911

The production of quicksilver in 1911 was the greatest since 1907, the total output being 21,256 flasks of 75 lb. each, valued at \$927,989, against a production of 20,601 flasks, valued at \$958,153, in 1910, according to an advance chapter by H. D. McCaskey, from 'Mineral Resources of the United States for 1911.' California was the greatest producer in 1911, with 18,860 flasks, valued at \$867,749, and the remainder of the quicksilver came from Nevada and Texas. While there was an increase in the output of quicksilver last year, the amount produced was over 5000 flasks below the average annual output of 26,609.5 flasks for the decade ending with 1911. Until Texas began production in 1899, California supplied practically the entire output of the United States for the last half of the nineteenth century.

The annual domestic consumption appears to have been in recent years from 18,000 to 21,000 flasks, or about equal to the domestic production. The decrease of domestic stocks and higher prices in 1911, however, caused an increased importation of quicksilver—the heaviest in many years—from 667 lb., valued at \$381, in 1910, to 471,944 lb., or 6293 flasks, valued at \$251,386, in 1911. On the other hand, exports of quicksilver decreased from 1923 flasks, valued at \$91,007, in 1910, to 291 flasks, valued at \$13,995, in 1911—the smallest export in many years.

Discussion

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Insertion of any contribution is determined by its probable interest to the readers of this journal.

Zinc and Lead Mines

The Editor:

Sir—In your issue of the *Mining and Scientific Press* of June 8 you have a short article purporting to be a review of the lead and zinc activities of the various states, in which the writer thereof stigmatizes the lead mining industry of the Joplin district as a "rather attractive gamble" or as a "pretty speculation." Naturally the man engaged in mining here and with first-hand knowledge of the industry resents any such imputations, for the industry is not only a well established one, but the field offers to the industrious operator, engineer, or mining geologist such clear indications that prospecting and mining in this district to the student of actual conditions, not mere theories based on textbook knowledge, has passed beyond the 'gamble or speculation,' either ugly or 'pretty.' Of course we have our 'gambles,' and we have 'old-timers' selling out. We have our bad promotions no less so than other mining districts, nor more so either. For a man like yourself, who has known the hospitality of the district, made some attempt to study it, even issued a report upon it for the United States Geological Survey, to allow a journal of national importance to openly slur and insult the largest and most important zinc district in the United States seems to me incredible, and I trust that you are not personally guilty of the discourtesy and gross misstatement of facts.

OTTO RUHL.

Joplin, Missouri, June 13.

[We commend the promptness and fervor with which Mr. Ruhl flies to the defense of a district for which we own a partiality, but we do not agree that the language of our correspondent involves any open 'slur or insult' to the district. Lead and zinc deposits are as a class notoriously irregular, and in the case of the 'shallow diggings' at Joplin, to which the context shows our correspondent specifically referred, one "invests money at the risk of loss on the chance of unusual gain," and that, according to the *Century* dictionary, constitutes speculation. Men have made a profit of over \$100,000 in 18 months from an expenditure of less than \$10,000; we have also known them to make nothing from an equal expenditure, and, if anything, the last mentioned investors used the greater care and had the benefit of the more competent advice. As geologists and engineers, we would like to believe that mining can be freed from risk, but the facts are to the contrary, and we must pin our faith to the overbalancing 'unusual gain' that may fairly be expected from a certain portion of our ventures. There are men and companies that make money at Joplin and in other lead and zinc districts through times of high and of low prices alike, but to do so necessitates large capital, so as to spread the risk and average the loss. The attractiveness of lead and zinc mining for the ordinary small investor, and it is especially attractive, lies in the fact that it is always possible to enter the business with small capital expenditure and that at certain times the profits are so large as to make a "very pretty speculation" even for him who must put the bulk of his eggs in one small basket. Our correspondent was pointing out, and in this we join him, that, in view of the high price of metals, now was an especially good time to invest in lead and zinc. We are glad to note that in the Joplin district alone, \$400,000 in new capital is said to have been recently invested. That \$175,000 should have come from so careful a concern as the Consolidated Mines Selection Co., speaks well for the district. In Montana, on the Pacific coast, and all up and down the Rocky Mountains, there is an active search for zinc. The movement is not confined to America, as is

shown by the interest in Australia and the building of plants in Japan. Zinc consumption is increasing, and a margin that in tonnage loomed large a few years ago is now small when measured in percentage of output. All of which gives proper comfort to zinc producers.—EDITOR.]

An Unusual Type of Mill

The Editor:

Sir—The mill of the Fort Bidwell Consolidated Mines Co., as described by W. G. French, in your issue of June 22, has one novel feature—that the rock-breaker is on a level with the battery floor and an elevator is used to throw the ore into the bin to be fed to the stamps. In your issue of January 21, I described this 5-stamp mill as follows: "The mill has 5 stamps, 1000 lb. each, with mortar set on concrete base, battery posts made of 12 by 28-in. timbers set in cast-iron sole-plates on concrete base. For a mill of this size I consider it most economical for the rock-breaker to be placed on the same level as the battery, with an elevator to the ore-bin. The rock-breaker is here under the care of the battery-man, for in a mill of but 5 stamps one man is easily capable of doing all the work. There are other advantages in this construction, such as less height needed for ore-bin, no vibration from breaker communicated to bin or building, the breaker is always in sight of the millman and does not run for hours without attention, as is often the case when in the attic of the ore-bin, and the dust, if any, is at once settled on the ground instead of filtering down from the ore-bin to every part of the mill.

"It was found on excavating for the millsite that what appeared to be a porphyry bedrock was underlain by tough blue clay of unknown thickness. Ten holes 4 ft. deep were drilled into this clay, the bottoms sprung with one-third of a stick of powder, and 1-in. rods, previously upset, were cemented in and turned over at the top. The concrete was laid on this foundation."

It will be seen from this that the rock-breaker was put on the battery-floor level with the five stamps. This mill was erected primarily to treat the Mountain View ore; which is a strictly free-milling ore, as 80 to 90% can be extracted on the plates. The idea of putting in a tramway to the Sugar Pine mine and the addition of another five stamps were later considerations. The ore-bin was divided into two compartments, one for the coarse ore and one for the fine and the broken rock from the breaker. Mr. French says the whole product goes to the rock-breaker. This is not so; there is a grizzly for the ore from the Mountain View mine, as well as for that from the Sugar Pine.

When ore was developed in the Sugar Pine mine it was decided to build an aerial tramway. To save the expense of building up the ore-bin another story and also to allow as much fall as possible between the two terminals, for the tramway goes over a mountain, I decided to leave the rock-breaker as it was and use the elevator as hitherto. There was no trouble and a rock-breaker man was not necessary. It was then decided to put in another five stamps. This was done with snow on the ground, and shortly after the machinery arrived it was impossible to get in any more freight. On making the excavation for the new five stamps it was found that the bed of blue clay dipped downward, necessitating a higher battery block. As I only had on hand enough cement for the usual size of block I fell short, and had no means of getting any in. What more natural than that I should adopt the form of construction that in other cases has proved successful (Silver Peak, for example), namely, a wooden base on top of the concrete for the mortar to set on. Some may call this poor construction, but while not as good as an all concrete block, it is still good.

The boiler and engine in use for the five stamps was sufficient to run ten stamps and a rock-breaker on a pinch, but could not run ten stamps, a rock-breaker, the tramway, and elevator, and I informed the officials of the company that five stamps must be shut down during the time the rock-breaker and tramway were running. I had in mind at the time that power would have to be increased; for the Sugar Pine ore, not being free milling, would re-

quire a cyanide process, and more power would then have to be applied. This second battery was put up, but not completed, for it has no ore-bin. I put in a temporary chute to lead ore from the present bin to the new battery, simply to try it. As a consequence of this lack of ore-bin the structure is not as stable as it should be. The first stamps in this respect are excellent, there being almost no vibration at the base of the battery posts.

It may be well for would-be critics to consider a few items. The staff correspondent of the *Mining World* states: "This also applies when the Ft. Bidwell Con. company spent \$40,000 on a 10-stamp mill, and tried straight amalgamation, which saved but 15% of the heads on \$100 ore." The 10-stamp mill, with tramway included, did not cost \$20,000, and the original purpose for which the mill was put up was to treat the Mountain View ore, on which it saved not only 15%, but as high as 85%. The Sugar Pine ore did not come until later, and while the mill saved better than 15%, the company was not in a financial condition to install an expensive cyanide plant without some knowledge of the conditions that the ore required.

Last year the first team got to the mine in July, and the season practically closed in November. Both mills were erected with snow on the ground, and if anything was missing it was necessary to do without it. This required some figuring at times. These mills and tramway were put up by myself with what local help I could train. The one carpenter I had for a short time was very poor on rough timber work. The construction of both mill and tramway was made of hewn timbers, which cost much less than sawed lumber. This was particularly so of the tramway, which crosses a rough mountain, with the timber growing nearly where it was used.

Bishop, California, June 24.

Alaskan Development

The Editor:

Sir—After a continuous residence for the past eleven years in Alaska, and having been a close observer on the ground of the conditions prevailing here, I am led to the conclusion that the views of all writers on Alaskan development, including the utterances of W. L. Fisher and Gifford Pinchot, are much too narrow and distorted to form a safe and successful basis for government action. The main discussion in the press has magnified the importance of the Bering river and Matanuska coalfields out of all due proportion, where we are considering the 600,000 square miles of Alaska as a whole. A. H. Brooks, of the U. S. Geological Survey, estimates that under the most favorable conditions for shipment, the ocean transportation of Alaskan coals would not amount to more than 1,000,000 tons per year, which is a small matter when we are considering the development of so large a public domain as Alaska.

As matters now, and for a long time past—more than ten years—stand, the fuel and timber supply of Alaska have been so bottled up that they have not been available for use in the development of Alaska; and that is the reason why Alaska has made no increase during that time in population or its industries. Under present conditions the territory is on the decline, and must so continue until a governmental policy is inaugurated as liberal and encouraging to both labor and capital as that under which the 'States' were so successfully developed. We must still now, as in all our past, depend entirely on the prospector and pioneer to discover the natural resources and on capital to develop them. This seems too apparent to require further consideration. Neither of these forces will embark in development work without the promise and prospect of suitable reward. That reward always has been, and presumably always will be, the choice of ownership by the discoverer. The government leasing system of our lead and copper mines from 1807 to 1849 proved a dismal failure and cost the public much more to administer than it returned in rentals. Many citations by various writers of other countries, where it is said government leasing systems of public

lands are operating successfully, are entirely misleading, for they fail to further inform the reader that all these leasing systems provide that the lessees may any time during the term of the leases purchase the leased lands at a price stated in each lease. A half truth may be more misleading than a whole lie. All writers on Alaska entirely overlook the paramount fact that the coal and timber is of vastly greater importance in promoting the development of the frost-bound region than for all other purposes. In fact, Alaska never can be developed to any but a limited extent without the practically full and unlimited use of the coal and timber scattered to the farthest interior. Of the 12,000 square miles of coal measured, so far as at present known, the larger percentage of acreage lies far from water transportation, but contiguous to the many mountains containing the mineral deposits. Though most of the interior coal measures carry lignite coal, it is of greater value in developing the interior than all the coal in the Bering river and Matanuska fields because of its proximity to places of local consumption. Railroad lines are important, but much less so than are the interior fuel and timber in the early development of Alaska. Unless the Government shall build railroads into the undeveloped portions of Alaska, and that comprises all Alaska except a narrow strip along tidewater, these roads will not be built until development shows their need, or until they will pay to operate. Building railroads in Alaska much ahead of development by private capital is out of the question. It would be like building mills to treat ore before the mines were found and sufficiently developed to produce.

Leaders of ultra conservation who found their theories before they (or, indeed, anyone in the States) knew enough about conditions in Alaska to frame a 'working hypothesis' will fail in the end to reap renown or benefit Alaska by blinking facts that are sure to come to the people in the near future. Alaska is too large a national asset to remain long unknown. Even though the Government could secure net returns, which I emphatically deny, under a leasing system applied to any of the resources of Alaska, it seems clear that if such system should retard the development of that territory it would not be desirable, for all admit that the speedy development of Alaska is paramount in importance. Unjust and extortionate treatment of Alaska, either by the government or by capital should not be permitted. The urging of a leasing system as a cure for such an evil is idle and foolish in the extreme. Everyone knows that the American people are demanding that capital shall be controlled, and the present administration is actively working to that end. Either the people will succeed in controlling or regulating capital, or our government will take the form of a plutocracy instead of a republic. If our government cannot prevent robbing by the rich and powerful in the States, it cannot do it in Alaska. Any leasing system that does not confer the right of the lessee to purchase will not develop Alaska. It will, on the contrary, drive out of business, and finally out of Alaska, every prospector, pioneer, and poor man seeking to acquire land for himself and his children. All Alaskans, given their preference, favor the right to purchase what they discover, and their views will be views of all who think of coming to Alaska. Who then will develop Alaska? Of all men it is not likely to be the man back East who sits in his easy chair and writes for public consumption and with the hope that he is making a national figure of himself. Alaskans are as like as two peas to the post-army of frontiersmen who were seeking fortunes and homes in the unexplored wilds that have marked our frontier boundary since the landing of the Pilgrim Fathers. They, of all men, knew best how to develop the regions they explored. The country wisely listened to them for a hundred years and never once found them in error. Will the country listen to them once again, or turn a deaf ear and follow the leadership of the ultra-conservationists as applied to Alaska? Alaska has thrown down the shovel and pick and stands anxiously awaiting an answer.

JULIUS THOMPSON.

DENVER, COLORADO

IMPROVEMENT IN MINING CONDITIONS.—HUDSON MILL.—
SMUGGLER-UNION AND THE LIBERTY BELL.—ZINC IN
DEMAND.—WAGES AT ASPEN.

The general status of the mining industry in Colorado shows improvement over the conditions that have existed for the past few years. Manufacturing companies and engineers are active, and the prospect for a steady improvement is good. The state has about passed through a period of depression which was the result of a number of causes, chief among which were exhaustion of high-grade ore deposits, inability to treat low-grade ores at a profit, and diversion of capital into irrigation and land enterprises. The first of these has not been remedied and there is no immediate prospect or hope that it will be; but the second and third causes of our depression have been largely overcome. The treatment of low-grade ore is no longer a serious problem from the metallurgical point of view, and the tendency to withhold money from irrigation and land projects has resulted naturally from an excess of such schemes and a deficiency of water. There is, therefore, a strong probability that more capital will now be available for sound mining ventures.

Following the lead of the Hudson mill in the Idaho Springs district, where success was attained in cyaniding silicious sulphide ores having an average value of \$10 per ton, the owners of the old Newhouse tunnel have decided to erect a large custom mill at the tunnel mouth in which will be employed a combination process of amalgamation, concentration, and cyanidation. The plans call for a 300-ton sampling department, and three mill-units of 100 tons each. For the present only the first mill-unit will be constructed, and it will be completed and placed in commission this fall. Excavation has been started and machinery is now being purchased. The new plant will embody the latest in milling, and is expected to materially increase the mineral output of the district.

In the Telluride district the remodeling of the Smuggler-Union and Tomboy mills is progressing rapidly. At the former a complete cyanide equipment has been added for the treatment of slime, in addition to making changes in the stamp-mill, where Wilfley and Deister tables have replaced the old Gilpin county bumping tables. At the Tomboy mill some changes have been made in the ore-dressing system whereby the mixed lead-iron-zinc ore will be separated into three shipping products without the use of electrostatic or electromagnetic processes. The suit of the Smuggler-Union against the Liberty Bell for damages amounting to \$600,000 for trespass and unlawful extraction of 74,000 tons of ore, was heard in Denver during the first week in June. The case was hotly contested, and several experts were employed by both sides. Toward the end of the trial the Liberty Bell made a defense of innocent trespass and claimed that only 53,000 tons of ore had been taken from Smuggler-Union ground. The jury, seemingly, failed to consider the defense of innocent trespass, for in its verdict it awarded the Smuggler-Union damages amounting to \$403,000. This is one of the largest damage awards ever brought in by a jury in the federal court in Colorado. The Liberty Bell company will file a motion for a new trial.

Inquiry for zinc mines is greater than for many years past, and a number of important sales are being considered. Developed mines are scarce, but the satisfactory state of the metal market and the prospect of good prices for zinc has had the effect of stimulating search for prospects or partly developed properties. Owners of well developed mines are in a position to realize good prices for their properties, and are not anxious to sell under present conditions. The Leadville district especially is doing a good business in zinc ore, and a large tonnage of both carbonate and sulphide ore is being shipped. The smelters are taking carbonate ore of a lower grade than formerly, and some contracts have been made for ore carrying as little as 20% zinc.

The trouble at the Smuggler mine, Aspen, which resulted in temporarily closing that property June 5, has been amicably settled, and the men have returned to work. A question of wages was involved. The miners presented their case in a most courteous and friendly manner to the management, and the latter conferred personally with the miners at a public meeting. The following schedule was asked by the miners: timbermen, \$3.50 per day; machine men, \$3.50; miners, shovelers, and trammers, \$3. The schedule ruling differed from this only in the wages for shovelers and trammers, who were paid \$2.75 per day, as in the Leadville district. Although Mr. Davis, the manager, frankly pointed out to the men that he believed that wages should be graded according to skill, and that miners should properly receive a higher wage than trammers and shovelers, he acceded to their wishes and announced that the schedule proposed by the men would be adopted. As a pure question of sociology he believed that the change was wrong in principle, but, inasmuch as a similar change had been considered at Leadville, he was willing to be governed by the proposal of the miners. The possible effect of the change on the discipline of the mine was pointed out to the men, but they assured the management of their hearty co-operation in improving the efficiency of the work. It is expected that the mine will be in full operation about July 1, but future operation will depend on the success in bringing about economies which are so necessary in a low-grade mine.

JOPLIN, MISSOURI

PROSPECTING COMPANIES FOR PERSONS OF LIMITED MEANS.
—EXPERIMENT IN SHAFT RAISING.—CONCRETE COLLAR
TO PROTECT SHAFT FROM FLOODS.—ZINC AND LEAD
NOTES.

Co-operation in churn-drilling is becoming popular with persons of limited means in the Joplin district. The system may be adopted in other localities where mining conditions are similar. A company consists of 50 shares, the cost of each being \$5 per month. A secretary is chosen at a nominal salary, say \$25 per month. A churn-drill, costing possibly \$2000, is purchased on payments of about \$100 per month. These expenditures leave about \$125 per month to pay for the drilling expenses. Leases on virgin land are obtained at 10% royalty or less. If the company is fortunate in finding ore in any of the first few holes sunk, it is quite likely an operating company can be found to take over the lease at an advanced royalty. Thus the prospecting company may receive a royalty of 20 or even 25% of the ores sold, depending on its richness, and in turn pay the 10% royalty to the land owner. Or possibly the prospecting lease may be sold. In either case the shareholder reaps a big return on his investment. Several companies of this type are now operating in the district, and in almost every instance the shareholders are getting good returns.

At the Nowata mine a shaft is being dug from the bottom up instead of from the top down, and this is the only instance of the kind in the district. The shaft was started in the roof of a drift, 220 ft. beneath the surface. Hugh Correll, superintendent, is keeping careful cost figures and reports a great saving with the shaft now at a point about 100 ft. above the drift. The method of procedure is unusual. An ordinary 8-in. drill-hole was sunk at a point where it was necessary to sink the new shaft. This hole penetrated the drift. A boiler, hoister, and derrick were placed above the drill-hole and through it a heavy wire cable was lowered, being attached at the bottom to a substantial platform, containing an air-drill. The platform is raised into the shaft as though it were a cage. A drillman prepares the rounds of holes in the top of the shaft, which, in this case, corresponds to the bottom of the average shaft. A powderman loads the rounds; the cage is lowered to a point of safety in the drift, pulled slightly to one side to escape the shower of broken rock, and the shots are fired by electricity. All the costs of shoveling the broken rock into tubs to be hoisted and the heavy costs of pumping in a newly sunk shaft are eliminated. The saving in time also is proving a big factor in favor of this novel shaft-digging

system. The Yellow Jacket mine, in a district flooded beneath several feet of water when a near-by river rises, has overcome the trouble by the construction of a concrete collar about the shaft. By a small investment, O. W. Sparks, manager of the mine, has saved thousands of dollars which would have been expended in pumping. The collar is substantially constructed and is 6 ft. high; sufficient to rise above the highest floods on record.

Almost \$400,000 in outside capital, some of it from foreign countries, has been invested in Joplin mines within the past few weeks. The largest sale was that of the Mary C. mine, owned by Thomas Coyne, to the Consolidated Mines Selection Co., Ltd., of London, England, for \$175,000. The Taylor Snapp tract of 400 acres sold to the M. W. Sheridan Syndicate, of Chicago, for \$150,000. The Katy Lou mine sold to the Hydraulic Mining & Milling Co., of New York, for \$50,000. The Birthday mine sold to the Nonandoga company for \$5000. Zincblende is strong at \$53 to \$59, basis of 60% metallic zinc, with choice lots bringing \$62. Lead ore is stronger at \$58 to \$60.

BLACK HILLS, SOUTH DAKOTA

PRODUCTION OF WASP NO. 2.—ELECTRIC POWER FOR THE HOMESTAKE.—ELECTRIC FURNACE FOR DEADWOOD COMPANY.

Wasp No. 2, during May, paid \$15,000 in dividends. This was earned on the handling of 15,200 tons of ore that returned a little less than \$2 per ton. The introduction of a number of labor-saving devices, the most important of which is a steam-shovel for stripping overburden, has made this accomplishment possible. The ore is a quartzite, mined in open-cuts, and is crushed to about $\frac{1}{8}$ -in. mesh and cyanided. During the past month some unusually high-grade ore has been shipped to smelters, but the proceeds were not available for the May distribution of profits. This material has averaged more than \$250 per ton. It is only a small body, occurring under the quartzite, and is removed after the quartzite is mined, so that the tonnage is comparatively small, and no particular effort is made to hurry its production. General samples assayed around \$275 per ton, and the screenings gave better than \$8000 per ton. H. C. Osterman, who has a lease on the Merritt mine, at Galena, is opening up this old property and taking out a first-class grade of lead-silver ore. The streak is not large, but there is enough of the ore in sight to make it an attractive proposition. He intends to make regular shipments to the Omaha smelter.

The Kiemer Gold Mining & Milling Co. was recently organized with the following officers: H. H. Kiemer, president; Olaf Seim, vice-president; Mrs. Elizabeth R. Kiemer, treasurer; Jesse Simmons, secretary, all of Deadwood. The company has 210 acres of ground adjoining the city limits of Deadwood, where there is a large showing of phonolite porphyry. On the surface careful sampling has shown an average of \$5.20 per ton for a width of 30 ft., and the company intends to thoroughly develop this shoot. The Echo company, at Maitland, will soon resume work in its shaft, which is now 75 ft. deep, with the intention of quickly completing it to 200 ft. This decision was arrived at recently when some Eastern parties who are heavily interested in the property visited it. An electric hoist will be installed.

The work of electrifying the Homestake property is progressing at a good pace. All of the stamp-mills were equipped with the new power some weeks ago, and this week the work of placing motors for driving the crushers was completed. The crushers are put at the different shafts where ore is hoisted, and had previously been operated by independent Corliss engines. The New Reliance company has levied an assessment of 1c. per share to take care of floating indebtedness and make some few changes preparatory to starting the mill. Since the return of good weather the Bismarck company has put a good crew of carpenters at work on the completion of its mill, adjoining the Wasp No. 2, and every effort will be made to finish the plant this summer. The severe winter made it necessary to suspend

construction. The Deadwood Zinc & Lead Co. announces that it has decided to erect an electric furnace for smelting its ore. The ore carries about 9% zinc, 5% lead, \$5 gold, and 5 oz. silver per ton. There is an immense quantity developed, and tests which have been made assure the officers that electric furnace will save a high percentage of the contents at a moderate cost.

The Castle Creek dredge at Mystic is in operation, and will be put in condition to withstand the coming winter and operate continuously. Last year, the first season it operated, was productive of good results, both financially and from a technical standpoint. Several things were learned about the ground, with the result that during the winter suspension a number of changes were made that should increase the efficiency of the boat. The main trommel has been lengthened, iron rings inserted, and a pump added to throw a constant stream of water into the trommel. These changes are planned to break up clay balls which it was discovered carried off a portion of the gold. Other minor changes have been made. The Golden Summit mill at Hill City is operating continuously on a vein 5 to 6 ft. wide

WASP NO. 2 MILL.

that contains a 2-in. streak of rich ore. This material is being sacked. The Forest City mill near Hill City is rapidly nearing completion, and is one of the most complete 5-stamp plants in the Black Hills. This property contains a small body of high-grade ore, practically all of which is free milling.

WASHINGTON, D. C.

CONSIDERATION OF APPROPRIATION BILLS.—SURVEY APPROPRIATIONS VOTED.—ECONOMIZING ON THE BUREAU OF MINES.

Interest at Washington the last two weeks has naturally centred on the two conventions, none the less, business is being transacted. In the House the Sundry Civil bill was taken up June 14 and has brought out some sharp debate, though not the usual fireworks. After an earnest consideration of the food served at Soldiers' Homes, with reading in detail of menus that made the reporters want to go out and get a bite, the annual contest between the cow and the oleomargarine trust came up. This time the cow lost. In the course of debate on the proposal to abolish local Registers and Receivers of the land office, A. W. Rucker, of Colorado, tried to persuade Congress to turn over the remaining public lands to the States, but received little encouragement. The annual effort was made to reduce the appropriation for protecting the public lands from land thieves, after which the committee steam-rolled F. W. Mondell, who thought that at least \$50,000 per year should be spent in Wyoming on surveys. The Geological Survey appropriation aroused neither comment nor opposition, recalling the happy country that had no history, rather than 'the watch-dog's honest bark' that characterized the 'welcome as we drew near home' in the good old days of Holman from Indiana. However, the Bureau of Mines provoked a storm. The committee had granted an increase of \$35,000 for fuel testing, but the best efforts of M. D. Foster failed to get a special appropriation of \$50,000 for investigations and inquiries into the mining and treatment of ores and

other mineral substances,' and J. R. Mann, whose bright little snickersee is always working, saw to it that if there be any more mine inspection in Alaska it shall be paid for out of the general funds. The fact that the inspector was authorized to use a sleeping car if he could find one was too much, and the item was excised from the bill with a rush. So careful and virtuous had the Committee of the Whole become by that time that it indignantly refused to authorize the Secretary to accept land for laboratories or switch tracks for mine-rescue cars if offered for nothing to the Government. In the interest of economy rent will be paid. Then having corrected the totals and adjusted its papers the House passed to the next item, national parks, and hurried on the 'pork,' public building bills. In the Senate there has been much official debate over the army appropriation bill, and unofficial discussion whether F. E. Warren, of Wyoming, is to be allowed to keep his fort and promote his nephew. It is feared that the veto by the President will prove too popular and that a choice will need to be made between nephew and fort. Incidentally, the tariff has been discussed in a desultory way, but the tariff, like the poor, will always be with us, and no one feels hurried.

LONDON

REVIVAL OF INTEREST IN CORNWALL.—FORMATION OF NEW COMPANIES.—PROFITABLE OPERATIONS ON TAILINGS.

Cornwall is at the present time attracting attention once more, and appears to be at the threshold of another period of renewed prosperity. For instance, John Taylor & Sons are assuming the management of the Droskyn and Wheal Ramoth tin mines near Newquay. A syndicate called Droskyn Syndicate Limited has been formed with a capital of £7000 to acquire these ancient shallow mines and to carry out the preliminary work advocated by James Roberts, who is the prime mover in the scheme. The re-entry of John Taylor & Sons into Cornish mining is a noteworthy event. It is to be hoped that their experience this time will be more fortunate than their last venture in East Cornwall, namely, Drakewalls. They are now starting on rational lines, and, before erecting expensive mining and ore-reduction plant, propose to test the property by clearing and unwatering the Droskyn hoisting shaft and then extending the 40-fm. level on the main lode in both directions, and proving the backs so laid open by means of raises. If this preliminary work gives satisfactory results, a company is to be formed with a nominal capital of £118,000, of which £60,000 will be working capital. It is satisfactory to note that the grantee of the lease is content to transfer the option in exchange for 8000 fully paid shares in the larger company when formed, so that the whole of the capital of the syndicate is available for prospecting. The formation of the West of England Tin Corporation is another noteworthy event. This private company has been organized to acquire and deal in mining claims in the West of England, and generally to act as an exploration company. The capital is £50,000, all of which will be available to carry on operations. The directorate includes John Gilbert and Horton Bolitho, both of Carn Brea & Tinerof Mines, and A. V. Agar Robartes, while E. S. King is associated with the company. It is interesting to find that Lord Clifden, through his son, is active in the revival of the country's chief industry, and it is to be hoped that some of the other large landowners will follow his excellent example. Such a company as this can do much to direct attention to the mineral resources of Cornwall, and, controlled by practical men, should have a successful future.

The reward of vigorous development in a good district is clearly shown by recent discoveries made on the Carn Brea & Tinerof, and the lesson should not be lost sight of by those other mines in the country which are content practically to mark time in this respect. The 320-fm. cross-cut has intersected Duncan's lode at 97 fm. from Martin's East shaft. The full width is not yet known, but for the first 8 ft. it assays 30 lb. of black tin per ton. It is interesting

to note that it was estimated by the late management that this cross-cut would reach the lode at a distance of 65 fm., but at the shareholders' meeting in February last, when already 80 fm. had been driven, Mr. King, who had re-surveyed the position, said he thought 100 fm. would be nearer the mark, and this proves to be the case. A good deal of criticism locally has been leveled at Mr. King on this point, but he must now be glad that he stuck to his guns. The other discovery is the North lode at the 160-fm. level from Highburrow East shaft, which, at the point of intersection, was 3½ ft. wide and assayed 90 lb. of black tin per ton. This lode, however, has always been patchy where worked in other parts of the property, so it will be safer to await further development before working much of it. Ten rock-drills are now in operation at Carn Brea & Tinerof solely on development. For the first five months of the year 34,328 tons of ore has been treated, producing, according to the ticketing sales, 411 tons of black tin, or 27 lb. per ton. The concentrate has realized £47,281, or an average price of £115 per ton. It is quite evident that the current six months will show record figures all round, and the gross profit should exceed that shown in the best half-year so far in the company's history, when an amount of £10,162 was earned. In spite of the greater development, the normal working cost has not increased, although, of course, the advance in the price of coal owing to the coal strike had an adverse effect, for 1,500,000 gal. of water is being pumped each 24 hours by the five pumping engines. Experiments have recently been made by Mr. King with a revolving buddle, which, by means of scythe-shaped knives, automatically removes the three products, concentrate, middling, and tailing, and so does away with the heavy labor involved by the shoveling on the buddle, a point to which visiting engineers to Cornwall have so often directed attention.

The Cornwall Tailings Co. started eighteen months ago to treat the vast dumps at Carn Brea & Tinerof. The moving spirits financially were Australians connected with Broken Hill and other mining interests in the Commonwealth. The results obtained show that the company is one of the most profitable, if not the most profitable, in all Cornwall. A review of the yearly report for the period ended February 29 last will be of special interest. A profit of £11,264 was made, out of which a dividend at the rate of 25% was paid. In addition, a reserve fund has been set aside for depreciation, amounting to £5000. The tonnage treated was 62,578 wet tons, including the re-treatment of 6643 tons of by-products; thus the weight of tailing handled from the dump was 55,935 wet tons, equal to 47,535 dry tons, assaying 20.9 lb. of metallic tin per ton (as compared with 19 lb. for the previous year), and containing a total of 442 tons of metallic tin. From this was recovered 277 tons of black tin, containing 170 tons of metallic tin, the gross value of which was £31,380, which, less smelter charges, £3534, and cost of purchase, treatment, etc., £12,658, left a working profit of £15,188, from which head-office charges, depreciation, etc., £3924, must be deducted to arrive at the net profit of £11,264, stated above. The recovery of 170 tons of metallic tin equals an extraction of 38.5% of the tin contained in the tailing as shown by chemical analysis. The interesting statement that 13 lb. of black tin per ton was extracted, whereas the vaning-assay of the tailing only showed 10 lb. per ton, makes it clear that, on a large scale, a more complete extraction of slime tin is possible than by the vaning-assay method. The gross value of tin extracted per ton of wet tailing was 11s. 2½d., less smelting costs, 1s. 3d., leaving 9s. 11½d. per ton. The costs of purchase, treatment, etc., including the re-treatment of by-products, amounted to 4s. 6d. per ton, leaving a profit of 5s. 5½d. per ton. The new pipe-line, through which it is proposed to pump the tailing by aid of water, will shortly be at work, and this change from carting the stuff, it is anticipated, will save 5d. per ton. It is estimated by Arthur Richards that there still remains 1,100,000 tons of tailing for treatment. Ross K. Macartney, for several years chief engineer at Mount Bischoff, has recently been appointed general manager of the works.

BOSTON

STRIKE AT REFINERIES AFFECTS COPPER STOCKS.—REPORT
OF LAKE COPPER CO.—UNFAVORABLE SHOWING OF
UTAH CONSOLIDATED.

The East has not yet had a repetition of the extremely hot weather which last year characterized June and July, and caused a considerable curtailment of copper refinery output, but there has been something of a stand-off with last year's conditions in the strike situation at Baltimore and Perth Amboy. This strike affecting the Guggenheim interests, has been protracted for over a month and will undoubtedly be a substantial factor in holding down the copper deliveries to be announced by the Copper Producers' Association early in July. It seems that labor complications came at the psychological moment to further strengthen copper metal conditions. With the further decrease of visible stocks abroad, and the trouble experienced at these important Eastern refinery plants, there is no prospect of any increase in copper stocks during the summer, and the chance of cheaper copper seems remote. The political situation has apparently no bearing upon copper metal sentiment. There is a strong combination of natural trade forces sustaining copper even at the present high levels, and this seems to measurably override any unfavorable factors in the market.

In the Lake Superior district the possibility of important lode discoveries keeps Boston guessing. The Houghton Copper Co., the shares of which are traded in on the Curb here, has lately been active and advanced in quotations. This is due to the company finding the rich west lode which was opened up by the adjoining Superior mine. Houghton has heretofore been a neglected and inactive stock though its developments are reported to have been for some time in favorable ground. The present discovery is said to be one of the richest showings ever made south of Portage lake. Houghton has a small share capitalization and its position, sandwiched between Isle Royale and Superior, gives the stock a prospect of much promise. News recently received from Isle Royale, Superior, and Houghton points to important ground being opened in that territory. The Hancock shaft has cut at the bottom rock heavily impregnated with copper, that is believed to be the Pewabic lode, making the subsequent proceedings of great importance to Boston. The annual report of the Lake Copper Co. has been the subject of study. It showed a balance of quick assets over all indebtedness of \$87,512, of which \$59,462 was cash. Notwithstanding this greatly reduced amount of working capital, William A. Paine, president of the company, gives the assurance that no new financing will be necessary. The company has placed and paid for all of its important equipment, and is now developing its capacity to shipments of 500 tons of rock per day. From these shipments, and a 17½¢ copper market, it is figured that the company will be self-sustaining. Lake now has the benefit of an experienced and conservative management. Lake is a rich mine and should make good, despite the fact that its recovery now is but little better than 15 lb. of copper per ton. This does not include mass and barrel copper, which is shipped direct to the smelter, enabling the company to increase its average content somewhat above the present recovery. The trend of the Lake lode has not yet been definitely ascertained. The dip to the west is now less than it was some months back, and while extensive underground work has been done, no intelligent theory as to its direction or correlation with other formations in the district can be made.

It is evident that Utah Consolidated, at one time the greatest mine of the Bingham district and the lowest cost copper mine in the world, is in danger of passing. For the past two or three years Boston has been receiving periodical sensational accounts about the decline of this property. Last year certain Boston interests, believing that the management had acted disingenuously with the stockholders and the public in the giving out of particulars concerning the physical condition of the property, made an effort to

wrest control from the Broughton crowd. The effort came within an ace of succeeding, though it was not renewed this year. Early in the year, Boston was regaled with the naive statement that Utah Consolidated was fast turning into a lead mine. It will be remembered that it was originally a gold mine, at a time before Bingham developed into importance as a copper producer. When the mine turned into a copper producer, for a period it was considered the biggest copper mine in Bingham. The facts now seem that Utah Consolidated has been gouged of all its rich ore and has only about 200,000 tons of copper ore running a little better than 2%, helped out by about \$1.25 per ton in gold and silver. Added to this is a small tonnage of lead ore, but the lead developments to date have been disappointing, and no shipments of lead ore are being made at present.

KALGOORLIE, WESTERN AUSTRALIA

The April production of the important mines of Western Australia was as follows:

Name.	Tonnage.	Value.	Profit.	Div'd.
Associated	10,530	\$70,500	\$8,500
Associated Northern...	1,282	20,500
Burbans Main Lode...	1,700	21,000
Golden Horse-Shoe....	24,269	169,000	9,500
Golden Ridge	2,936	26,300	8,500	*\$34,500
G. Boulder Perseverance	20,758	106,000	7,000
G. Boulder Proprietary.	17,702	235,800	129,000	*\$328,000
Great Fingall	5,557	50,500	5
Hainault	5,622	32,400	2,500
Ivanhoe	20,330	190,400	80,000	†\$350,000
Kalgurli	10,310	106,000	45,000	†\$120,000
Lake View & Star....	17,704	105,000	17,000	†\$50,000
Mountain Queen	3,735	17,000	5,600
Oroya Black Range....	4,700	42,500	13,200
Oroya Links	11,010	66,500	16,500
Sons of Gwalia	†\$101,000
Sons of Gwalia South..
South Kalgurli	9,351	59,500	13,400	†\$37,500
Yuanmi	4,280	43,500	20,400

*March. †April. ‡May.

The Perseverance made \$7000 profit on the treatment of \$4.80 ore. The April gold output from the state was valued at \$2,420,000.

Labor troubles of a petty nature have upset the smooth working of the mining industry. All the foundries have been shut down now for ten weeks, and the molders are just returning to work after a signal defeat. As a result of the strike the Lancefield mine is closed indefinitely, although the eighth level at present shows 23 ft. of ore worth \$9 per ton. The company was out of repair parts and was forced to stop work. Over 400 men are out of employment. The finances of this company are somewhat involved, but will probably be now adjusted. The latest producer, the Yuanmi, is also down on account of the trammers demanding more wages and refusing to submit to arbitration. There has also been trouble with the engineers at the Ivanhoe, though that is now settled. The Gwalia South is to be closed, and the property sold to the Sons of Gwalia for \$27,500, if the shareholders agree. The company has not done well of late, and has examined many properties with a view to purchasing a new mine. Work on the water-supply for the Ora Banda and Marvel Loch districts is now being rushed. The plant of the Associated Northern at the former place is somewhat behind, through the molders' strike and the water not being ready. There has been little heard from the Poynesville district of late. Some six months ago it promised fairly well, although the lodes were small. The Associated is looking better of late, likewise the Oroya Links. Cross-cutting from the Edwards shaft of the Boulder at 2650 ft. the Horse-Shoe has cut No. 4 lode from the east, and 460 ft. from the northern boundaries; assays are high. At the 210-ft. level, Bullfinch main shaft, the south cross-cut of the west drift at 44 ft. cut a mineralized vein, from 49 to 67 ft., which was 28 in. wide and assayed \$18.70.

General Mining News

ALASKA

COPPER RIVER

Shipments of copper for Seattle, in May, were 1,720,391 lb. This brings the total for the first five months of this year up to 14,455,589 pounds.

JUNEAU

The report of the Alaska Treadwell G. M. Co. for May states that 84,280 tons of ore was crushed and 1585 tons of concentrate saved. The estimated value of the free gold was \$104,555.37; of the concentrate, \$88,970.63. The value of the total production was \$193,526, with a realizable value of \$191,590.74. The estimated net profit was \$71,602.19. The yield per ton of ore milled was \$2.30. The stock of broken ore was increased 2926 tons, and development for the month amounted to 929 feet.

VALDEZ

The Mineral Creek Mining Co. has found a vein of rich ore in an adit driven during the winter to prospect for an ore-shoot showing at the surface. Where the vein was cut it was only 18 in. wide, but in a drift the ore has widened to 28 in. Samples taken have assayed from \$50 to \$100 in gold with 30 oz. of silver per ton. This ore is higher in silver than any yet discovered in the district. The Kenai M. & M. Co., operating placer ground on Copper creek, has discarded its hydraulic elevator and will operate its claims this season by hydraulic mining. Prospecting has proved the ground to contain \$1 per yard, but this amount has not been recovered by the elevator. The company has several giants ready for operation and a good head of water from a ditch line supplied from Stetson creek.

ARIZONA

GILA COUNTY

(Special Correspondence.)—Superior & Boston continues to ship ore from the stope below the sixth level on the Great Eastern vein and is preparing to reopen the Limestone shaft and mine the ore that is blocked on the second and third levels of the Limestone vein. A winze has been started on the shoot of ore disclosed by the drift on the twelfth level on the Great Eastern vein. Crosscuts are being driven east and south on this level. Enlargement of the Copper Hill shaft of the Arizona Commercial continues. After the foreclosure sale in July, it is proposed to erect at this shaft the double-drum hoist now at the Eureka shaft and connect it with an electric motor. Power will be transmitted from the Old Dominion power-plant. Compressed air for the drills will also be furnished by this plant and development started below the fourth level. The Old Dominion company is canceling many of the leases on its various properties on account of the passage by the state legislature of the miner's lien law which provides that liens shall attach to mining claims for debts contracted by lessees.

At the Miami mine construction has been started on the new mine machine-shop and the new change-house at No. 4 shaft. These buildings will take the place of the ones at No. 2 shaft, which are situated directly over the orebody and will have to be abandoned, as the extraction of the ore by the caving system progresses. No. 4 is the permanent working-shaft and is situated at some distance from the orebody.

The Guggenheims have relinquished their option on the Needles group of 27 claims and the so-called independent group of 13 claims, three miles west of Miami and adjoining the claims of the Southwestern Miami and the South Live Oak development companies. The claims contain a considerable area of mineralized schist that is believed to hold possibilities for the development of a body of low-grade copper ore similar to the Miami and Inspiration deposits. The option called for total payments of \$625,000. The ground was examined by five of their engineers at various times, and orders have been placed

for machinery and supplies for churn-drilling, but it was finally decided not to prospect the property.

Underground work has been discontinued at the Black Warrior mine. E. M. White, the manager, says that this is temporary, and that development and mining will be resumed in three or four weeks, after the construction work now under way is completed. A new stable and warehouse are being erected at the mine, necessitated by the recent sale of the camp-site to the Inspiration company for the erection of its proposed 7500-ton concentrator. Ore that has been accumulating in the bins is being shipped. At the Duquesne mine, seven miles northwest of Miami, three men are mining the gold-lead ore on contract and about 100 tons of ore is on the dump ready for shipment. The ore occurs as free gold and lead carbonate with limonite-stained quartz at and near the intersection of fissures in limestone closely associated with porphyry dikes and averages \$15 to \$25 per ton in gold and lead.

Globe, June 20.

PINAL COUNTY

The Ray Consolidated Copper Co. is increasing the output of the mines, and the June shipments to the Hayden plant are expected to exceed those of May, when 2100 cars, estimated to hold 126,000 tons of ore, were delivered to the concentrator. The foundation for the new compressor has been finished, and the building is well under way. The excavation for the foundations for the hoist and crusher at the No. 3 shaft is being rushed, and the foundations will be begun in July. The electric pump that was recently placed in the Humboldt shaft has drained the water entirely from the central section of mine No. 2. A precipitating plant consisting of 600 ft. of launders is being erected in Copper canyon at the southern extremity of No. 2 mine. If the results of this are satisfactory, another plant will be placed near the entrance to the same mine. A new hospital will be erected by the company at Ray to replace the one now maintained at Kelvin. The business portion of the town of Ray was recently swept by a fire which caused damage estimated at \$400,000, with about 5% covered by insurance.

YUMA COUNTY

The Horn property in the Turtle mountains, about 20 miles southeast of Parker, has been bonded to William Neagle, in the interest of W. A. Clark. Work will be resumed at once. The shaft is to be deepened and development carried on in the adits where orebodies are exposed. The machinery for the new mill to be constructed near Rineon Landing in the Whipple Wash district, has arrived, and the work of assembling the machinery and erecting buildings started.

CALIFORNIA

INYO COUNTY

The May production of the Skidoo Mines Co. is reported as \$17,720, from 1209 tons of ore milled. The cost of development for the month was \$1504.18, and of operation \$7202.08, giving a net profit of \$9013.74. Lost time in mill operations during the month amounted to 10½ days.

MODOC COUNTY

(Special Correspondence.)—At High Grade the snow is rapidly melting, roads are being opened, and active prospecting has commenced. A number of lessees are operating on claims in the district. The Sunshine company, which recently passed into the hands of Charles Fulton, B. N. Dawson, and associates of Los Angeles, has leased the Lucky Dutchman to R. L. Wade and Fred Schrott. The Ajax, Cedar, and Gold Stripe claims have been taken by A. Keitel, F. D. Sherry, and associates of Denver. The April Fool claim, near the Sunshine, has been acquired by Frank M. Myers, who is supposed to represent San Francisco people. The Del Floy has passed under bond and option to F. L. Evans, of Portland, Oregon. On the Shasta View, which is reported under a three-years lease to George Kent, of Seven Troughs, Nevada, the prospect shaft is down 50 ft. and is advancing to the 120-ft.

point. It is also reported that the property of the Fort Bidwell Con. Mines Co. is to be opened to lessees, and that the company plans to mine the developed ore and to order a cyanide plant.

Fort Bidwell, June 21.

PLUMAS COUNTY

The Old Bullion quartz mine, on the Indian Johnson property, half a mile west of Greenville, has been leased again, and will be reopened for development. In early days the property was worked by various lessees, but the shaft was allowed to fill with water several years ago, and the mine was abandoned. The shaft is now being drained and the seepage water shut off. The mine, as far as it has been developed, showed one small vein of rich ore.

COLORADO

JEFFERSON COUNTY

The new experimental ore-dressing and metallurgical plant built for the Colorado School of Mines at Golden, at a cost of \$125,000, will be opened July 1. Plans for the building were drawn by Frank E. Shepard, president of the Denver Engineering Works Co., and were approved by D. W. Brunton and Philip Argall. The plant is in charge of W. Traphagen, and William G. Haldane is manager.

TELLER COUNTY (CRIPPLE CREEK)

Operations have been resumed on the 1000-ft. level of the Camilla shaft. The shaft-house was destroyed by fire about two months ago, and it was necessary to shut down to make repairs to the machinery. In a drift at the 1000-ft. level a vein had been cut two days before the fire, and development will now be continued at this point. The Beacon hill property of the Black Belle G. M. Co. has been divided into four leasing blocks, and reasonable working conditions and low-grade royalties are provided in the terms of the contract. In the Orpha May mine of the Stratton estate a large orebody has been found. The mine is operated through the deep shaft of the John A. Logan claim adjoining, and the ore was discovered in a cross-cut from the 1000-ft. level of the Logan shaft. The ore is low grade, and from 9 to 12 ft. wide, so cheap mining is possible. Twenty sets of lessees are now engaged in the development of the Raven and Gold hill holdings of the Doctor-Jack Pot Mines Co., and shipments are being made from the Lugham, Lucky Corner, Jack Pot, and Doctor mines. The ore shipped averages about \$20 per ton, but from this the company is paid a fair sum in royalties. The main building of the Gaylord mill, at the Dante mine on Bull hill, has been enclosed, and work has commenced on the other mill buildings. The machinery will be placed as soon as delivery is made at the mine, and it is expected that the plant will be in operation by September 1.

The annual report of the Findley Con. Mining Co. shows that the company operated at a loss of \$2189 last year. The output of the mine was 3597 tons of ore which netted \$19,378. During the year the company drove 1331 ft. of cross-cuts and drifts and 300 ft. of raises. A promising orebody was opened on the twelfth level, but it extended only 100 ft. upward, and as soon as it was exhausted the company abandoned underground operations. Negotiations are now under way for the sale of the low-grade ore dump. The company recently organized a new corporation, the Findley Mines Co., incorporated under the laws of Wyoming, with a capital of 2,000,000 shares with a par value of 2½¢ each, instead of 1,250,000 shares of \$1 each which was the old capital. Shares will be issued in number equal to those outstanding so the *pro rata* interest will be the same. The new company takes over all the property of the old.

IDAHO

BONNER COUNTY

The Idaho Continental mine, north of Priest lake, and 23 miles from Parthill, will be equipped with a concentration plant. John D. Ryan, president of the Interna-

tional S. & R. Co., has advanced \$150,000, which will be used for the purchase of machinery required for a 300-ton concentrator, a hydro-electric power plant, a 12-drill compressor plant, and a sawmill, and also for the erection of the buildings necessary to house the machinery and furnish accommodations for the employees. At a recent meeting of the directors of the Idaho Continental company, a ten years' contract was signed with the International S. & R. Co. which gives the latter company the right to handle the entire output of the mine. The road from Parthill to the mine is to be prepared so that auto trucks may haul machinery and ore in the summer months. Ore-sheds of large capacity will be built for the storage of the winter output. The Idaho Continental group consists of 20 claims, on which \$100,000 has been spent in the last two years, developing the mine to a depth of 500 ft. Several years ago the mine was operated for a time, and several tons of high-grade silver-lead ore shipped. The property was examined recently by Frederick Burbidge, of Spokane, formerly general manager for the Bunker Hill & Sullivan company; Reno H. Sales, chief geologist for the Amalgamated Copper Co.; and Fred T. Greene, formerly with the Amalgamated Copper Co., but now a general mining engineer at Butte; and their reports agree on an estimate of \$1,000,000 net of ore in sight above the 500-ft. level.

IDAHO COUNTY

The Mineral Zone group of eight claims, two miles north of Elk City, has been sold by Mrs. M. A. Parr to J. R. Painter. This group of claims was recently examined by J. H. Mackenzie and B. C. Austin in the interest of Fred W. Bradley, of San Francisco, who held an option on the property pending the examination. After the final report Mr. Bradley was unable to make terms acceptable to Mrs. Parr, and upon the lapse of the option the claims were immediately bought by Mr. Painter. The Colonel Sellers and Enterprise claims are considered the most important of the group. Upon the Colonel Sellers a rich shoot of ore was found last winter while assessment work was being done. It is reported that a body of ore 125 ft. long and 5 ft. wide has been opened, with an average value of \$30 per ton.

MONTANA

LINCOLN COUNTY

(Special Correspondence.)—The Vermillion Silver & Lead Co., owning quartz claims near the boundary line between Sanders and Lincoln counties, will begin shipping ore about July 1. Four men are engaged in running an adit in on the vein, and this adit is now in 225 ft. As the mountain is very steep, they have a depth on the vein of nearly 400 ft. The vein is about 7 ft. wide, with a streak of shipping ore about 20 in. wide. The ore contains gold, silver, and lead, and the average value of the entire vein is about \$12 per ton.

Libby, June 22.

SILVERBOW COUNTY

(Special Correspondence.)—The East Butte Copper M. Co. has filed a report with the county assessor which shows that in the year ended May 31 the net earnings of the company were \$250,187.32, as compared with \$118,986.84 for the preceding year. The output of the mine during the year was 94,532 tons of ore, with an average yield of \$16.51 per ton, making a total gross yield of \$1,560,660.52. The cost of mining was \$4.31 per ton, and the treatment charges were \$4.91 per ton. Transportation and selling charges amounted to \$225,288.88, while additions to the mine and surface equipment cost \$11,795.30. An item in the report of \$202,080.85 is called 'smelter deductions' and represents the difference between the assay value of the ore and the actual smelter recovery. The total expenditures were \$891,226.83. At present the East Butte company is producing copper at the rate of 1,400,000 lb. per month, and the value of the May output was \$260,000.

The Butte mines payroll for May was \$1,350,000, which is \$100,000 greater than any month since 1907. It is expected that the June payroll will even exceed May, and

that by the close of the month of July the wages paid the miners of Butte will total a million and a half a month. This does not include the payrolls of the Washoe and Great Falls smelters of the Anaconda company.

The Montana chapter of the American Mining Congress has been formally organized. Among those who became associated with the chapter are John Gillie, general superintendent for the Anaconda company; E. P. Mathewson, manager of the Washoe smelter; A. B. Wolvin, president of the Butte & Superior; Sam McConnell, superintendent for the Butte Central Copper company; C. J. Stone, manager of the Butte-Alex Scott; Oscar Rohn, manager for the East Butte company; John D. Pope, manager for the North Butte company; Ed. Hickey, president of the Tuolumne company; W. B. Fisher, manager for the Davis-Daly company; Charles W. Goodale, J. C. Adams, and B. H. Dunshee of the Anaconda company.

Butte, June 22.

The North Butte M. Co. mined 411,908 tons of ore in the year ended May 31, 1912, as compared with 429,511 tons in the preceding year. The report on the year's work contained the following comparison of results, per ton treated:

	1912.	1911.
Yield	\$10.16	\$8.64
Mining	4.19	4.11
Smelting	3.43	3.36
Total expenses	7.77	7.23
Profits	2.39	1.41

NEVADA

ESMERALDA COUNTY

The Jumbo Extension Mining Co. has taken a lease for a year on the Bonnie Clair 20-stamp mill, 3S miles south of Goldfield. Experiments have been made on the ore which indicate a profitable return after the payment of all charges. E. S. Van Dyck, manager for the company, estimates that there is enough ore on the dump and in the slopes of the Polverde workings, adjoining the Clermont on the southeast, to keep the mill running for a year, treating 100 tons per day. Development has been carried on in the Polverde for a year, and the ore deposit is now proved from a point below the 900-ft. level to a point above the 800-ft. level, a distance of 275 ft. along the dip. Along the strike it is proved for a distance of nearly 300 ft. It ranges from one foot to ten feet in thickness. Portions of the body will produce a good grade of shipping ore, and the balance a good grade of milling ore, but it is intended to break the entire mass as a whole and thus deliver a higher-grade milling product, with an average value, according to samples taken for milling tests, of \$20 per ton. The company also owns claims in Diamondfield that aggregate about 66 acres. Lessees are now operating these claims and report the discovery of a vein with 2 ft. of \$28 ore and 4 ft. of \$7 ore.

The Blair M. & M. Co. has purchased, in Goldfield, machinery for a mill and cyanide plant of 50 tons daily capacity. This company owns a group of six claims, and has taken a bond on the Barton mine, a mile from the Pittsburg Silver Peak. The plant will be on the site of the old Blair mill, the ground having been leased from the Pittsburg Silver Peak, and ten 850-lb. stamps of the old plant will be used with the new equipment. The flow-sheet of the new mill was designed by Willett Barton, formerly mill superintendent for the Florence Goldfield Mining Co. The ore will be crushed in a Phillips 9 by 15-in. crusher to 1/4-in. size; then by finishing rolls and the ten stamps through a 20-mesh screen. Dorr thickeners will be used in the mill, and the final precipitation will be by the Merrill process. The water for the plant will be furnished by the Pittsburg Silver Peak company from its main pipe-line, and the electric power will be supplied by the Nevada-California Power Co. The new company already has in sight about 5000 tons of milling ore, and about 1400 tons is on the dump at the mine. The mill tests conducted on this ore indicate that it will average about \$18 per ton, and that a profit can be made on \$8 ore. Development on

the old Barton mine has been resumed, and other properties which have milling ore exposed will be leased. The plant will also be conducted as a custom mill, and it is intended to treat the low-grade silver and base ores found in the district. W. O. Bradley, manager for the Pittsburg Silver Peak company, has been aiding the new enterprise and the mill tests have been conducted at the Silver Peak plant. E. R. Noyes, of Goldfield, president of the new company, and C. V. Bob, general manager, hope to have the mill ready for operation in August.

LYON COUNTY

The report of the Nevada Douglas Copper Co. covering the period from December 1911 to and including March 1912 shows receipts from ore settlements, gypsum mining, and miscellaneous sales, of \$152,428.89. The expenditures of the company for development, mining, maintenance, and general expense amounted to \$105,599.84. There was also \$33,101.29 due from sales of copper in accordance with contract. The total profits for the period were therefore \$79,930.34. The total assets of the company were given as \$6,265,350.95, including all property, investments in the Nevada Copper Belt railroad, and treasury stock.

NYE COUNTY

The Adaven Mining & Smelting Co. has leased its property to George Wingfield, who will operate the plant and eventually become one of the largest stockholders. The company owns a group of claims near Marble in the Lodi district and a fully equipped modern smelter. The ore, which is low grade, is a carbonate carrying lead, gold, and silver, with the gold in higher proportion than in most silver-lead mines.

In the Mizpah Extension mine a body of good ore has

THE TONOPAH-BELMONT SHAFT.

been found in the east drift on the vein on the 1000-ft. level. The shoot, which is 3 ft. wide, has been opened for 50 ft. in the drift, and by a short raise. The average assay of the samples runs from \$9 to \$12 per ton, but there are occasional small kidneys of specimen ore which show ruby and native silver. The vein has not yet been identified with any of the known veins in the Belmont company's territory. In raise No. 9 on the shaft-vein of the Tonopah-Belmont from the 1100-ft. level, a shoot of ore 5 ft. wide has been opened. When this vein was cut in sinking, no ore was found, and the present discovery is therefore encouraging. On the thirteenth level, both east and west drifts on the vein continue in good milling ore. The work of building ore-bins on the head-frame of the shaft is progressing, as is also the construction of the automatic railway to both the waste dump and crushing plant. New 1 1/2-in. cables, each 1800 ft. long, together with heavier sheave wheels, have been placed on the head-frame, to handle the safety cages and the 3-ton skips. At the new mill the piping is being placed, and a trial run will soon be made of the tube-mills and pumps on the tank floor. The refining-room is nearly completed, the precipitate presses, melting furnaces, and slag crusher are all in place. The mill is expected to be in operation by July 1, but the old mill at Millers will be run until August, as at least a month will be required to get the new plant into smooth running order. The output of the

Montana-Tonopah for May was 4611 tons, and the same rate has been maintained in June. In stope 162 on the shaft-vein a good body of rich ore has been found which is being used to grade up the poorer ore from some of the lower levels. This vein, which is flat, is being explored on all levels from the 162 intermediate down to the 700-ft., and a cross-cut is being driven to pick up the downward extension of the vein on the 765-ft. level. The May output of the Tonopah Extension was 4497 tons, and of the West End 3206 tons.

WHITE PINE COUNTY

(Special Correspondence.)—The Copper Mines Co. has commenced shipments from the mine in the Robinson district to the Steptoe smelter, on the same basis that the ores of the Giroux are treated. The Copper Mines Co. has 3000 tons of sulphide ore on the dump which will average 15% copper. This ore is produced on the 215-ft. level and from a winze 75 ft. in depth which is going down on a 4-ft. vein. Ore with less than 6% copper will be shipped to the concentrator at McGill.

Ely, June 20.

The Giroux Con. Mines Co. is now shipping 1000 tons of ore per day to the Steptoe plant. A part of this ore is coming from the stock piles of the Morris and Bunker Hill, but the mines are now hoisting fresh ore from the stopes. The Bunker Hill is now equipped with skips, and 500 tons of ore can be hoisted daily from the shaft. The Morris shaft is also equipped to handle a large tonnage, but the underground workings are not in condition for a large output. The old dumps are being loaded by a steam shovel with a clam-shell dipper at the rate of 15 to 20 cars per day, and in a few weeks the stock-pile ore will be entirely cleaned up.

NEW JERSEY

The strike in the Perth Amboy plant of the A. S. & R. Co. has been settled. The men have been granted an increase in wages of 10 to 15 cents per day. Two months ago a bonus system was put into effect, and the present advance, which the men will now receive, equals the bonus which was paid to them heretofore. So the men are really returning to work with no increase.

NEW MEXICO

GRANT COUNTY

The fourth section of the Chino Copper Co.'s mill will be started in July, and the fifth section in August, according to D. C. Jackling. An average of 3000 tons per day is now being treated by three sections of the concentrator. The stripping is well ahead of the mining, and the tonnage can easily be increased.

PENNSYLVANIA

(Special Correspondence.)—The University of Pittsburg School of Mines announces a change in the undergraduate courses. The purely elective system has been replaced by the group system, four groups of studies being provided: Group I, Mining, with two options, one in general mining and one in coal-mining; Group II, Metallurgy, with two options, one in general metallurgy and one in metallurgy of iron and steel; Group III, Geology; Group IV, Ceramics. The work of the first two years is common to all courses, and is intended to lay the broad foundation necessary for all engineering. A course in management intended to train men along executive lines, has also been arranged as a graduate course. For practical men who cannot afford the time to take the full mining course, short courses have been arranged, intended especially for those who desire to secure a fire-boss' certificate, a foreman's certificate, a state mine inspector's certificate, or a training for mine electrician.

UTAH

SALT LAKE COUNTY

It is reported that the Yampa mine will resume operations July 1, and the smelter will be started later if the showing in the mine is satisfactory. The Yampa company

closed its smelter nearly two years ago, when an excellent contract was secured with the Garfield plant of the A. S. & R. Co. Later when the smelter refused to renew the contract the mine was closed. An examination of the property by engineers of the Utah Consolidated demonstrated a large body of low-grade ore which can be worked profitably at the present high price of copper. The May production of the Utah Copper Co. was 10,068,336 lb., the largest in the history of the company.

The Michigan Utah Consolidated company has started the construction of a tramway to extend from the old City Rocks adit to Tanners flat. This tramway will consist of fourteen towers of concrete and steel, protected against snowslides and so arranged that the cables may be operated unless several successive towers are removed. Ores from other companies will also be transported over the cableway, and a hoist will be placed at the City Rocks adit where connection was made with the Solitude adit 300 ft. below. The Solitude adit will still be used for development purposes and all waste will be transported to dumps on the Big Cottonwood side.

UTAH COUNTY

The Beck Tunnel Con. Mining Co. has issued its report for the year ended June 1, 1912. The production of the mine was 4241.57 dry tons of ore, with a market value of \$46,141.62. The silver produced amounted to 68,381 oz. and the gold to 840.3 oz. Operating reports show 1816 ft. of development for the year, with costs per ton as follows:

OPERATING COSTS

	Mining.	Development.	Total.
Supplies	\$0.011	\$0.015	\$0.026
Explosives	0.287	0.136	0.423
Lumber and timber.....	0.034	0.007	0.041
Blacksmith	0.116	0.052	0.168
Power	0.168	0.168
Air	0.473	0.089	0.562
Water	0.015	0.002	0.017
Payroll	3.747	0.406	4.153
General office	0.460	0.460
Totals	\$5.311	\$0.707	\$6.018

These costs were further distributed to show purpose for which the money was expended.

MINE

		Per Ton.
Development	\$16,365.05	\$3.429
Tramming	1,030.07	0.216
Hoisting	4,232.49	0.890
Surface expense	1,440.90	0.302
Surveying and assaying	1,100.83	0.230
General expense	1,162.85	0.244
Totals	\$25,332.19	\$5.311
Exploration	3,374.64	0.707
Total	\$28,706.83	\$6.018

PLANT

		Per Ton.
Supplies	\$175.84	\$0.037
Lumber and timber	13.06	0.003
General office	135.00	0.028
Totals	\$323.90	\$0.068
Buildings and fixtures	31.56	0.007
Cars and tracks	22.34	0.004
Machinery	270.00	0.057
Totals	\$323.90	\$0.068

The treasurer's report shows cash on hand at the beginning of the period, \$3722.90, and an overdraft at the end of the year of \$1296.21.

The Yankee Con. Mining Co. has found zinc ore in the old stopes, opened in the early history of the property, and is planning shipments to Oklahoma smelters.

CANADA

BRITISH COLUMBIA

The Granby smelter at Grand Forks is treating 22,000 tons of ore per week, nearly all of which is from the company mines. The total shipments of blister copper from the smelter amounts to nearly 10,000,000 lb. to date this year. A large portion of the Granby mine above the third level, that had been deprived of its pillar supports, caved recently, bringing down a large amount of ore that can be shipped at a small cost for handling.

ONTARIO

The ore shipments from Cobalt for the first five months in 1912 shows a decrease from a similar period in 1911 of 1236 tons, due to the increased proportion of ore now treated by concentration. The bullion shipments from the district show a corresponding increase, and give promise of an increased output in silver for the year. The shipments from January to May inclusive are as follows:

ORE	Tons.
Buffalo	517.47
Chambers-Ferland	193.60
Cobalt Townsite	6,569.61
Colonial	41.60
Coniagas	882.73
Crown Reserve	230.06
Hudson Bay	312.65
Kerr Lake	333.62
La Rose	1,527.66
McKinley-Darragh	1,123.56
Nipissing	874.54
O'Brien	244.98
Right of Way	153.48
Temiskaming	489.92

City of Cobalt	1,618.40	1,000.00
Colonial	1,698.00	1,018.00
Miscellaneous	16,268.81	10,798.64

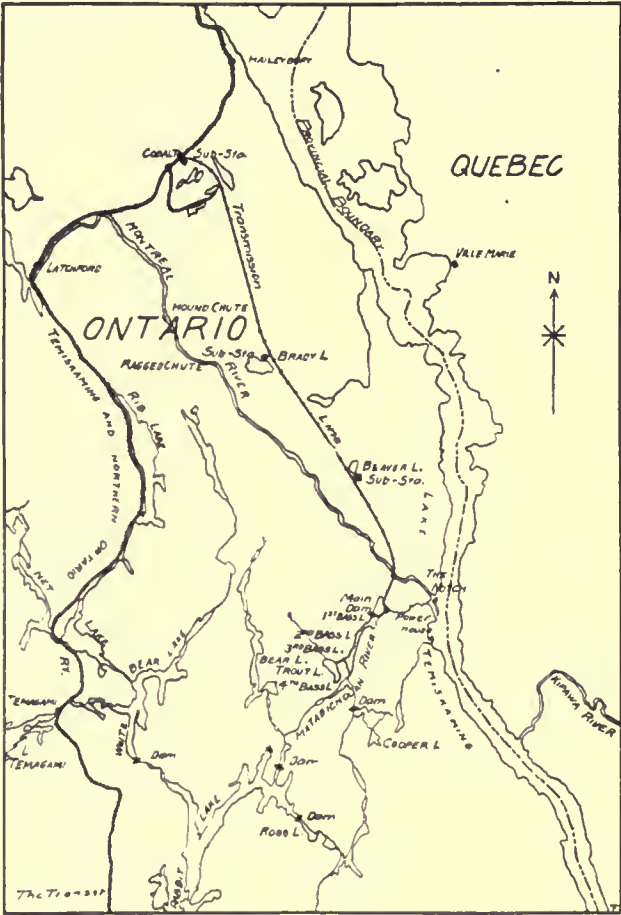

Totals 2,071,036.88 \$1,202,632.09

The Casey Cobalt Mining Co. has shipped a carload of ore, with the highest value of any single lot ever loaded in Cobalt. The ear contained 43¼ tons, which averaged over 5500 oz. of silver per ton. The total value of the ear was \$132,235. The best previous record for one ear was held by the Temiskaming at \$127,000 for a shipment made early in the year.

The Buffalo Mines, Ltd., has issued a report for the year ended April 30, 1912, which states that 50,167 tons of ore was broken in the mine during the year, of which 44,510 tons was hoisted and 5657 tons left underground. The mill treated 46,801 tons, averaging 32.35 oz., a total of 1,490,760 oz. with a recovery of 80.63% in the shape of concentrate weighing 1064 tons and averaging 1017 oz. per ton, and 1796 lb. of bullion. The cyanide plant treated 7744 tons of slime from the concentrator, averaging 10 oz. of silver, and re-

covered and turned into bullion 48,476 oz. The total recovery by milling and cyaniding was 1,250,453 oz., or equal to 83.88% of the original content. The financial statement of the company shows an income from mining operations of \$853,807.58, and from other sources \$3293.86. The expense of operation and administration was \$325,482.24 and for transportation \$80,465.01. From the net income of the company dividends to the amount of \$370,000 were paid, and \$81,154.19 added to the surplus, which now amounts to a total of \$389,577.67. During the year 1157 ft. of driving was done, and 53,864 sq. ft. of stoping.

At the Hollinger mill 10 stamps have been put into operation dropping on ore, and the others will gradually be brought into action. It is reported that all the machinery

PART OF ONTARIO.

is running smoothly. The Vipond mill has also started ore through the crushers and is preparing to treat the full capacity of 150 tons per day.

MEXICO

SONORA

The production of the Greene-Canaanea Copper Co., including the output of subsidiary companies, for the past four years is given in the annual report as follows:

	1908.	1909.	1910.	1911.
Copper, lb.	19,128,000	45,547,689	45,491,500	44,897,466
Silver, oz.	449,246	933,549	1,159,789	1,295,297
Gold, oz.	3,046	5,877	5,570	5,892
Net income.	\$606,305	\$1,102,559	\$1,184,750	\$1,318,472

L. D. Ricketts reports that the Cananea Duluth mine has been opened to the sixth level. During the year 1911 the fifth and sixth levels were thoroughly developed and the main hoisting shaft was raised through. These levels are now ready for production. The orebody on these levels is not as wide as on the upper levels, but is richer in copper and contains notably more silver, so that the showing on the sixth level is better than any other level in the mine. The cost of the copper produced by Greene-Canaanea is given as 8.907c. after deducting a credit for gold and silver content.

Personal

Professional men are invited to send news of their engagements and travels. Such news is interesting to friends.

R. L. BEALS is in Nevada.

ROBERT LINTON is in New York.

S. H. BALL has gone to Europe.

ROY H. CLARKE has gone to Nome.

F. W. TWEEDY was in San Francisco.

VICTOR G. HILLS has gone to the Yukon.

F. L. GARRISON was at Ely, Nevada, last week.

F. L. SIZER has left for Arizona, expecting to visit Bisbee.

L. F. VOGT expects to return to Pittsburg about August 1.

GELASIO CAETANI has gone to Telluride, Colorado, for six weeks.

W. E. DEFTY has gone to Pinal county, Arizona, on examination work.

J. C. BRANNER has gone to the Hetch-Hetchy valley on professional work.

A. G. KEILLER has gone to the Aguacate mines, San Mateo, Costa Rica.

F. W. BRADLEY has gone to Alaska, expecting to return early in September.

DANIEL VAN WAGENIN has completed an examination of the Lander oilfields.

GEORGE W. EVANS has gone to northern British Columbia on professional work.

T. H. JENKS has returned to Denver from a professional trip to Nuevo Leon, Mexico.

F. D. FRASER is now superintendent of the North Star mine at Orient, Washington.

J. H. HARTLEY is with the Abangarez Gold Fields of Costa Rica, in charge of the Mina Guacimal.

HOWARD W. DUBOIS is on his way from Prince Rupert to the Quesnelle placers, in the Cariboo district.

F. H. PROBERT has gone to New York, on his way to London, expecting to be away about six weeks.

H. H. ARMSTEAD has gone to Colorado Springs, where he will remain a few weeks before proceeding to Guanajuato, Mexico.

E. J. SCHRADER has been appointed acting general manager for the Nevada-Rockland property, at Pine Grove, Nevada.

HOWARD POILLON has returned from a two-months' inspection of the vanadium deposits of New Mexico, Arizona, Colorado, and Utah.

J. H. NELSON has resigned as mill superintendent for the El Favor Mining Co. and is now with the Cia. Minera Barreno y Anexas, San Luis Potosi.

M. K. SHALER, who has been opening a placer mine in the Belgian Congo, has completed his work and is on his way home. His address temporarily will be 921 Ohio street, Lawrence, Kansas.

Obituary

THEODORE ALBERT, for a number of years president of the William Powell Co., died May 27 at his home in Cincinnati, Ohio.

JAMES MOFFET recently died at his home at Los Angeles, at the age of 75 years. Mr. Moffet was largely interested in the Orphan Girl mine, near Butte, and had large interests in Mexican mines.

SAMUEL P. LEWIS died at his home in Buffalo, June 10. The son of one of the first ironmakers to come from Wales to the United States, he was in the employ of the Illinois Steel Co. for nearly 30 years, finally going to the Lackawanna Steel Co., of which he was superintendent in charge of mills at the time of his death.

Company Reports

ROUND MOUNTAIN MINING COMPANY

This company was organized in 1906 with an authorized capital of 1,000,000 shares of \$1 each, to operate mines at Round Mountain, Nye county, Nevada. The company owns 222.08 acres of patented ground and 121.63 acres of unpatented ground. The seventh annual report, for the year ended March 31, 1912, shows that 874,018 shares have been issued. The quotation March 31 was 47c. per share. The report of the president, J. R. Davis, shows that during the year 54,915 tons of ore of a gross content of \$7.09 per ton was milled, yielding \$6.24 per ton, or 88% of the total content. The operating cost was \$4.96 per ton. Miscellaneous earnings made the net operating profit \$1.36 per ton. At the beginning of the year the ore reserve was estimated at 111,928 tons; at the end of the year it had been increased to 145,820 tons, of an estimated content of \$7 per ton, 7508 ft. of development work having been done during the year at a cost of 90c. per ton milled or 56c. per ton developed. For mine and mill construction during the year \$33,999.91 was expended. The following figures of production and operating costs per ton will be of interest:

	Per Ton.
Gross content of ore.....	\$7.09
Tailing loss	0.85
Net realization	\$6.24
Miscellaneous earnings	0.08
Shipping cost	\$2.00
Development	0.90
Milling	1.16
Bullion tax, transportation, marketing, insurance	0.07
Office expense, taxes and insurance, general expense	0.32
Depreciation	0.31
Litigation	0.20
Net operating profit	\$1.36
	\$6.32 \$6.32

DEXTER WHITE CAPS MINING COMPANY

This company, with an authorized capital of 1,000,000 shares, of which 777,475 have been issued, owns properties at Manhattan, Nevada, which are being operated by lessees. Previous operations by lessees have yielded 1249 tons of ore with a bullion return of \$44,579, yielding a royalty to this company of \$5121. In January 1912 this lease was purchased by John B. Kirchen and others, since which time development work has been carried on. The new lease, operative until November 1, 1913, provides for the performance of a specified amount of work per month and the payment of royalties on ore of \$5 grade or better. The chief feature of the report are the results of an examination of the property by S. C. Durkee, who concludes that 17,500 tons of ore of milling grade can be considered as developed, but gives no exact statement as to the estimated content of the ore per ton.

THE LUCKY TIGER-COMBINATION GOLD MINING COMPANY

This company, which has an authorized capital of \$8,000,000 in shares of \$10 each, \$7,153,370 having been issued, owns all the capital stock of the Tigre Mining Co., S. A., of El Tigre, district of Moctezuma, Sonora, Mexico. During 1911 the latter company mined 46,945 tons of ore, of which 1866 tons was shipped and the remainder milled; 5922 tons of old tailing was treated by cyanidation in addition to current tailing. This ore, which had an average content of \$27.75 per ton, was mined at a cost of

\$3.05 per ton and milled at a cost of \$4.33 per ton; other expenditure brought the total operating cost to \$14.825 per ton. The profits during 1911, after deducting depreciation of \$88,675, were \$328,846, and dividends amounting to \$357,601 were paid. During the year 46,980 tons of a gross value of \$23 per ton was developed, the total ore reserve amounting to 218,315, with a content of \$19.20 per ton, and 86,894 tons of tailing, of a content of \$9.17 per ton. During the year the new stamp-mill, cyanide plant, and electric-power plant were completed at a cost of \$50,104, \$221,208, and \$239,207, respectively. The work of this company was described at some length in the *Mining and Scientific Press* of March 16, 1912. For the purposes of the federal income tax assessors, the depreciation upon the investment per ton of ore mined has been fixed at \$6 and a depreciation of \$753,826 has been entered upon the company's books for ore mined during preceding years. During the past four years dividends amounting to \$1,267,601 have been paid. The following summary of mining and milling costs will be of interest:

	Per Ton.
Development	\$0.65
Stopping	1.129
Filling	0.037
Framing	0.472
Timbering	0.612
Hoisting	0.024
Pumping	0.027
Sorting	0.473
Blacksmith work	0.160
Sampling and assaying	0.096
Surveying	0.043
Superintendence	0.262
Mine construction	0.005
Mining cost	\$3.990
Stamp-mill:	
Crushing	0.458
Regrinding	0.062
Concentrating	0.456
Cyanide plant:	
Conveying and screening.....	0.131
Tube-milling	0.934

Precipitation	0.181
Melting	0.252
Alterations	0.360
Milling cost	\$4.287

Dividends

Copper Range has declared a dividend of 50c. per share. The Calumet & Arizona has declared a dividend of \$1 per share.

Superior & Pittsburg has declared a dividend of 30c. per share.

The Tonopah-Belmont M. Co. has declared a dividend of 25c. per share payable July 1.

The Nipissing has declared a regular dividend of 5% and an extra one of 2½ per cent.

THE agreement for amalgamation of the Kaiping (Chinese Engineering & Mining) and Lanchow coal mining companies, signed in January last, has been ratified by the Chinese Government and the British minister. The combination will be called the Kai-lin Mining Administration. The Kaiping company receives 60% of the profits and the Lanchow company 40% up to a total of \$1,500,000, above which there will be an equal division. On the expiration of ten years the Lanchow company will receive the right of purchasing the whole of the Kaiping properties at a price to be arranged.

Book Reviews

Any of the books noticed in this column are for sale by, or can be procured from, the MINING AND SCIENTIFIC PRESS.

COALFIELDS AND COLLIERIES OF AUSTRALIA. By F. Danvers Power. Pp. 412, ill., index. Crichtley Parker, Melbourne and Sydney, 1912. For sale by the *Mining and Scientific Press*. Price \$10.

Whereas there have been many books published describing the goldfields of Australia, this is the first comprehensive account of the great coalfields which now yield more in annual return, as they mean more for the industrial independence of the commonwealth, than the gold in all the states. In 1910 coal ranked first among the minerals won, with a value of £62,000,000, as against gold at £58,000,000 and silver-lead at £52,000,000. Australia contains the great coalfields of the Pacific. In New South Wales alone it is estimated that there is 115,000,000,000 to 150,000,000,000 tons of available coal, counting on mining as practicable to a depth of 4000 ft. In the other states there are important though smaller coalfields, and the industry is less well developed. Mr. Power has described not only the coal itself but the methods of mining and utilizing it. Following chapters on the nature and origin of coal, its sampling and analysis, irregularities in beds, gases in mines and ventilation, are several chapters describing the coalfields of the individual states. These chapters are succeeded by five in which are discussed coal-mining conditions in New South Wales, explosives, and the individual collieries. The last two chapters in the book treat, the one of the coal trade, labor conditions, analysis of coals, and rescue apparatus, and the other of the Victorian state coal mine; the latter chapter being contributed by G. H. Broome, the general manager.

In preparing the book, Mr. Power has read the literature of coal widely as well as studied the local industry. His general chapters are fresh and notably superior to those generally found in such books. He has quoted extensively from the work of M. R. Campbell, E. W. Parker, and J. A. Holmes, and their associates in the work started by the United States Geological Survey at St. Louis. Apparently the later work done at Pittsburgh by the Bureau of Mines, at Urbana, Illinois, by S. W. Parr and his associates, in Chicago by A. Bement, U. G. Abbott, and others, and the writings of David White were not available in New South Wales in time to be incorporated. This is to be regretted, since the book must probably stand for some time unrevised. American engineers will be mainly interested in the discussion of mining conditions and mining methods. As to the latter, Australians as well as Americans have built mainly on English models. The mines are opened mainly by adits and worked either by long-wall or by a room and pillar system much like that common through the Middle West. Shafts where sunk follow the English model, being round and brick lined. Steel tripplers seem to be common. In design, the Australians seem here to have something to learn from Americans if steel is to be economized. As to machinery, there is so much that is familiar that few American names are missing. Babcock & Wilcox, and Sterling boilers, Sullivan, Goodman, and Jeffrey machines, Norwalk compressors, Aldrich pumps, McEwan engines, show that good machinery is cosmopolitan. Even machines with strange names, such as the Pick-quick long-wall coal cutter used in the thin veins at Mt. Kembla, show many points of resemblance to foreign types. This particular machine is closely similar to the Lee long-wall coal cutter developed at Mystic, Iowa, about twenty years ago. The Australian type draws itself along by winding a rope, whereas the Iowa prototype could be made to cut to an irregular face, since it traveled on short rails and was fed forward by rack and pinion. However, the Lee machine never found any place for itself outside the field in which it was developed. The 'Pick-quick', we will hope, may do better.

It is interesting to note that this, the most recent man-

ual on coal-mining, is exclusively an Australian product. The author is lecturer on mining at the University of Sydney, and the publisher is equally an Australian. It is an excellent piece of work and a book well worth having.

H. F. B.

James Lewis & Son's Copper Report

Standard copper steadily advanced in price during the month of May, from £70 3s. 9d. to £75 10s. for cash, and £71 to £76 for three months prompt. This was due to the rapidly improved statistical position and the serious depletion of stocks, arising from the expanding consumption both in Europe and the United States in conjunction with diminished supplies. During the month European stocks diminished 6952 tons, and in view of the large export of 32,582 tons from the United States to Europe and the active demand for home consumption, a material reduction in the stocks of American refiners is expected to be announced in the course of this week, strikes having occurred at the works of two refining companies. About 60,000 tons of standard copper changed hands on the London metal exchange, and closing values on June 3 were £76 17s. 6d. for cash, and £77 7s. 6d. for three months.

European stocks have decreased 6952 tons and the visible supply 7302 tons during the month. The German consumption for the first four months of the year has increased 15,769 tons to 70,564 tons, as against 54,795 tons in the same period last year. The total European increase this year is 18,288. The demand continues satisfactorily for manufactured copper, and India is now coming into the market for the metal.

The total arrivals in England and France for the month were 13,683 tons and the deliveries 18,516 tons fine. The arrivals in England from Chile during the month were 1331 and the deliveries 1591 tons fine, and from other countries the arrivals and deliveries were 7422 and 11,219 tons respectively. The arrivals in Liverpool and in Swansea from the United States were 1727 tons bars, etc., and 495 tons plates, etc., equal to about 2211 tons fine copper. In London the arrivals were 275 and in France 4250 tons fine. The Chile Charters for the month were 1650 tons, including 650 tons for the United States. The total imports to date this year are 7655 tons and the deliveries 5544 tons less than during the same period last year.

Quotations June 3 were: Standard, £76 17s. 6d. for cash and £77 7s. 6d. three months prompt; English best selected ingots, £81 to £82, and tough cake £81 to £82 per ton, less 2½% delivered Birmingham; electrolytic wire bars, £78 5s. to £78 15s. net cash c.i.f.; 13s. 6d. to 13s. 9d. for ore of 20%; and 14s. to 14s. 3d. per unit for Chile regulus or American matte free from silver.

COPPER MINES are being opened in Hupeh province, China, not far from the iron mines of the Han-Yeh-Ping company. A portland cement plant is now in operation near Shih-hwei-yao, on the Yangtze, a wire-rope tramway being used to carry the barrels of cement to the warehouses, by the river.

Decisions Relating to Mining

Specially reported for the MINING AND SCIENTIFIC PRESS.

TIMBER AND STONE ENTRY—RESERVOIRS AND DITCHES

Reservoirs and ditches constructed by a placer claimant for use in connection with his mining operations on another subdivision are not such improvements as will prevent the acquisition of the land upon which they are situated under the Timber and Stone Act, for the reason that all patents granted under that act must contain reservations of all vested and accrued water rights and ditches and reservoirs used in connection therewith.

John H. Parker (Land Department), 40 Land Decisions 431. February 21, 1912.

MINING LEASES—CONSTRUCTION

Where a lease was executed to certain parties to work an asphalt mine over a period of 50 years on a royalty basis, and after four years of operation the lessees shut down their plant, owing to trust competition and failed to prosecute any further work during the next seven years, the lessor was allowed to cancel his lease, notwithstanding that he had been paid a nominal rental of \$20 per year while operations were suspended.

Breckenridge Asphalt Co. v. Richardson, (Kentucky) 146 Southwestern 437. April 3, 1912.

PATENT IMPROVEMENTS—MEASURE OF VALUE

In determining whether the requisite expenditure of \$500 in labor or improvements has been made upon a mining claim for which a patent is sought, the proper test is whether the reasonable value of the work performed or improvements relied upon amounts to that sum. Proof of the actual amount paid or the actual number of days spent in prosecution of such work is not conclusive. They are elements to be considered in arriving at the reasonable value, but the value of each of these elements must be shown to be reasonable in itself.

Samuel B. Beatty *et al.*, (Land Department) 40 Land Decisions, 486. March 6, 1912.

INNOCENT PURCHASER OF MINING CLAIM PROTECTED IN ALASKA

A lessee in possession of a mining claim in Alaska under an agreement to work the same continuously and pay over to the lessor a percentage of the minerals extracted is a purchaser for a valuable consideration within the meaning of the act of June 6, 1900, which protects such purchasers against prior unrecorded conveyances. And a prior conveyance is deemed unrecorded where it was not acknowledged in such a manner as by law entitles it to record—for example, where it has but one witness where the law requires two, and where an erasure and alteration was made subsequent to the acknowledgment.

Waskey v. Chambers (United States Supreme Court) 32 Supreme Court Reporter, 597. May 13, 1912.

LODE CLAIMS—SUCCESSIVE RE-LOCATION BY SAME PERSON

Where a locator had initiated several times the location of a certain claim, using different names for the claim each time, but had perfected only the last of these locations by making a proper discovery, his last location will be valid, providing the rights of third parties have not intervened before the location is finally perfected. The rule that a locator cannot, by re-location, extend the time within which the necessary steps must be taken to complete his location, does not apply if he perfects it before the rights of others intervene. The completion of a discovery cut already commenced, so as to make its dimensions conform to the requirements of law, is sufficient discovery work in this case to support the last location.

Eureka Exploration Co. v. Tom Moore Mining & Milling Co., (Colorado) 123 Pacific, 656. May 6, 1912.

Concentrates

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

PLATINUM coins were first struck in Russia in 1828 in an effort to make a market for the metal. Originally platinum trading was a state monopoly and the official price was fixed at about \$3.13 per ounce.

BEACH SAND containing gold and platinum occurs at many points along the Pacific coast. Attempts have been made frequently to work the material by some concentration process. Cost of handling and metallurgical losses have prevented any great success. Attempts to treat by direct cyanidation have met the difficulty of high cyanide consumption. It is claimed that large tonnages containing 80c. to \$1 in gold occur where available for reclamation by suction dredges.

SOFT COAL is often stacked in piles out of doors and requires no careful grading. Anthracite must be protected from the weather and means must be provided for careful handling at all times, and for sharp separation of sizes, as also for screening to remove all dust and small sizes before shipments is made. Anthracite especially is a fuel for winter consumption only, being used through the Northwest almost exclusively for domestic heating purposes. Its handling, therefore, becomes almost entirely a matter of receiving during the summer months, and storing in ample quantities for shipment to meet the demands of an entire winter, when navigation is closed and no shipments can be received by water.

MINERS' INCH as a unit of measurement of quantity of water was adopted to furnish an easy method of approximation. It may be roughly defined as the quantity which will flow through an orifice 1 in. square, with a head of 6½ in. on the centre. This is an inaccurate unit, since the quantity which will flow through a hole 2 in. square does not equal 4 times the quantity passing a 1-in. hole. Bowie found in 1885 that in California the unit varied from 1.2 to 1.76 cu. ft. per second. For this reason many states have fixed the value of the miners' inch in terms of feet per second; thus in California and Montana 40 miners' inches = 1 cu. ft. per second; in Colorado 38.4. In Arizona, Idaho, Utah, and Nevada 50 miners' inches is taken as equivalent to a cubic foot per second; this makes the miners' inch correspond to 1.2 cu. ft. per minute.

FIRE prevention is more important than putting fires out after they are started. This rests upon the construction of the building and upon management and internal administration. Buildings may be classified into fire-resisting, or what is ordinarily called fireproof construction. The choice lies between the steel frame skeleton, enclosed with fireproof tile, or that enclosed with reinforced concrete. There is little to be said in favor of one over the other, except that with reinforced concrete a more skilled control is required through all the building processes. The high first cost of this class of construction is justified by the long term of life possible. Up to date, no limit has been found of general acceptance, and a probable depreciation of 1% per annum seems the best available figure. The second type of construction is what is known as mill, or slowly burning construction. This means that while the interior construction may be combustible, the heavy plank floors and their massive supporting timbers offer no hidden spaces, nor are they readily attacked by flame. The third type is the ordinary, or light joist construction, particularly objectionable from the fact that it presents the largest exposed area subject to ready ignition, and is the most difficult, both as respects prevention and fighting of fire. Its low cost is offset by the expensive upkeep and the high rate of depreciation, averaging 4 to 4½% per annum.

Recent Publications

TECHNOLOGIC PAPERS OF THE BUREAU OF STANDARDS. NO. 7. THE TESTING OF CLAY REFRACTORIES, WITH SPECIAL REFERENCE TO THEIR LOAD-CARRYING CAPACITY AT FURNACE TEMPERATURES. By A. V. Bleining and G. H. Brown. 78 pp.; ill., maps, index. Washington, December 15, 1911.

TOPOGRAPHIC MAPS have been issued by the U. S. Geological Survey recently as below:

Biggs, California, in Butte county; scale 1:31,680.

Butte City, California, embracing parts of Butte, Colusa, and Glenn counties; scale 1:31,680.

Caldwell, Ohio, embracing parts of Morgan, Noble, and Washington counties; scale 1:62,500.

Canal Dover, Ohio, embracing parts of Carroll, Stark, and Tuscarawas counties; scale 1:62,500.

Kosmosdale, Kentucky-Indiana, embracing parts of Bullitt, Hardin, and Jefferson counties, Kentucky, and Floyd and Harrison counties, Indiana; scale 1:62,500.

Meridian, California, embracing parts of Colusa and Sutter counties; scale 1:31,680.

A map of North America (28 by 38 in.); scale 1:10,000,000 (approximately 158 miles to 1 inch).

Catalogues Received

STEPHENS-ADAMSON MFG. CO., Aurora, Illinois. 'The Labor Saver,' May issue.

ALLIS-CHALMERS CO., Milwaukee, Wisconsin. Pamphlet No. 4028, 'Pulverator.' 8 pages. Illustrated. 3½ by 6¼ inches.

DENVER FIRE CLAY CO., Denver, Colorado. Pamphlet, 'Antidote to Cyanide Poisoning.' 4 pages. Illustrated. 6 by 9 inches.

CHICAGO PNEUMATIC TOOL CO., Chicago. Pamphlet, 'Chicago Pneumatic Compressors.' 12 pages. Illustrated. 3½ by 6¼ inches.

INGERSOLL-RAND CO., 11 Broadway, New York. Form No. 4021, 'Jackhammer Type BCR-43 Drill.' 12 pages. Illustrated. 6 by 9 inches.

MANHATTAN DRILLING CO., 25 Broad street, New York. Catalogue No. 51, 'The Dobbins Core Drill.' 20 pages. Illustrated. 6 by 9 inches.

NELSON VALVE CO., Philadelphia, Pennsylvania. Catalogue S, 'Nelson Steel Valves and Fittings.' 62 pages. Illustrated. 5 by 8 inches.

HYATT ROLLER BEARING CO., Newark, New Jersey. Bulletin No. 604-E, 'Hyatt Roller Bearings as Applied to Mine and Industrial Cars.' 24 pages. Illustrated. 7 by 10 inches.

MACOMBER & WHYTE ROPE CO., 507 South Clinton St., Chicago. Catalogue K, covering its line of wire rope, including patent Kilindo non-rotating wire rope. 72 pages. Illustrated. 7 by 10 inches.

BROWN HOISTING MACHINERY CO., Cleveland, Ohio. Catalogue J, 'Brownhoist Cranes.' 42 pages. Illustrated. 6 by 9 inches. Also Pamphlet S, 'Brownhoist Suspended Bins.' 36 pages. Illustrated. 6 by 9 inches.

INGERSOLL-RAND CO., 11 Broadway, New York. Form No. 4204, 'Are Valve Tappet Rock Drills'; 16 pages. Illustrated. Form No. 4111, 'Type "BC" Hammer Drills'; 16 pages. Illustrated. Form No. 7004, 'Cameron Steam Pumps'; 12 pages. Illustrated. All 6 by 9 inches.

HYATT ROLLER BEARING CO., Newark, New Jersey. 'Something About Hyatt Roller Bearings.' This is a beautiful specimen of printing as well as an interesting description of the plant of this company. The various departments are handsomely illustrated and a perusal of this book will convince the reader of the superior equipment and the careful attention given to the manufacture of Hyatt roller bearings. 52 pages. 9 by 12 inches.

Commercial Paragraphs

THE NEVADA ENGINEERING CO. has a contract for a 10-stamp mill for the Esmeralda Mining Co. at Gold Circle, Nevada.

THE DORR CYANIDE MACHINERY CO. of Denver announces that its offices are now situated at 733-5 First National Bank building.

Two units, each consisting of thirty-two 8-ft. diameter HARDINGE conical pebble mills, are about to be constructed at Lake Linden for the regrinding of the copper tailing which will be reclaimed from Lake Linden.

THE ABENDROTH & ROOT MANUFACTURING CO., with general sales offices at 50 Church street, New York City, announces the appointment of the Mexican Steel Products & Machinery Co., 208 Mutual building, Mexico City, as general agents for the company in Mexico, handling the complete line of Root water-tube boilers, Root spiral riveted pipe, and hydraulic mining machinery.

A. Vander Naillen, Jr., who for many years conducted the school of mines bearing his name, now announces that he has become associated with the HEALD'S SCHOOL OF MINES in San Francisco. He has arranged at the school, 425 McAllister street, suitable rooms which visiting engineers, architects, surveyors, and draftsmen may make their temporary headquarters without charge. A reference library, desks, drawing tables, and instruments are provided, and they are open to use by all engineers.

THE MANHATTAN DRILLING CO. has purchased the patents for the 'Dobbins Core Drill,' and is now manufacturing various types of Dobbins machines, and also operating a general core-drilling contracting business. Offices are maintained at 25 Broad street, New York. One of this company's drills at the Battery Park building, No. 24 State street, boring a 6-in. well has reached a depth of 500 ft., and at this depth is drilling from 10 to 16 ft. per 9-hour shift. At the Grand Central Station a class 'M' drill, boring a series of 6-in. holes, has averaged over 19 ft. per 9-hour shift.

In spite of the fact that the Mexican rebels still insist on making trouble along the American border, mining is going on briskly in the lower and middle sections of Mexico. Some inconvenience is caused to mining machinery manufacturers in trying to get machinery into the country. As an instance, the OLIVER CONTINUOUS FILTER CO. recently had occasion to ship a filter to the Cubilete Mining Co. at Ocotlan, Oaxaca. Instead of shipping this filter by rail direct by way of Mexico City, it was shipped by steamer from San Francisco to Salina Cruz on the west coast, thence by rail by way of Santa Lucrecia to Veracruz, and from Veracruz to Ocotlan.

Announcement was made June 1, 1912, that the three associated companies, the ALBERGER CONDENSER CO., ALBERGER PUMP CO., and the NEWBURGH ICE MACHINE & ENGINE CO., will in future be known as the ALBERGER PUMP & CONDENSER CO. The officers of the new company are George Q. Palmer, president; William S. Doran and D. H. Chester, vice-presidents, and William R. Billings, secretary-treasurer. The main offices are at 140 Cedar street, New York. The large amount of condenser and centrifugal pump orders in hand has demanded important additions to the plant and equipment of the company's works at Newburgh, New York. Important orders are being executed for the U. S. Navy Department, Isthmian Canal Commission, U. S. War Department, American Gas & Electric Co., Public Service Corporation of New Jersey, Cleveland Electric Illuminating Co., The Robin's Dry Dock & Repair Co., and many others of the largest corporations in this country and its dependencies. The line of apparatus manufactured by the Alberger Pump & Condenser Co. consists of surface, jet, and barometric condensers of various designs, cooling towers, a complete line of volute and turbine type centrifugal pumps, steam turbines, feed water heaters, hot water service heaters, and expansion joints.
